MOUNDING UP. The first soil used in mounding should invariably be the forkings, well broken up, from the sides of the trenches. That allows ample scope for the later mounding. The soil should in all these operations be well broken and be fairly dry, doing it in treacherous weather on such dry days as can be found, as in some soils, especially in wet weather, small slugs are plentiful. It is well before adding fresh soil to give it on each side of the rows a liberal dusting with fresh slacked lime, as that helps to destroy the pests and to keep the Celery clean. Good cultivators make it a rule before commencing to earth up the plants to get them fairly strong first. That condition is readily helped prior to the earthing by having a trench which will retain water or liquid-manure. Once the mounding begins, such waterings are difficult, if not impracticable.

Then, every soil is added, all short, immature leafage and stems, and especially any suckers which may have formed at the bases of the plants, should be pulled away, as these often harbour slugs and hinder efficient blanching. Anyone anxious to have the blanching as perfect as possible will find it worth while to tie the stems of each plant with hast a little loosely, as that prevents soil from getting into the hearts, and greatly facilitates good earthing up.

A. D.

POTATOES IN KENT.

The remarks of "J. C.," on page 314, are, unfortunately, too true. Considering the lack of rain in Kent, the disease is very prevalent, and I have observed it, especially in the Maidstone district. Some varieties appear more liable to attacks than others, yet it is impossible to judge by this alone. My Potato ground is completely open, and is adjoined by numerous other plots. The only variety to show the disease to any extent is British Queen, and strangely enough it is confined solely to one half of that variety. Most of the plots around are in a deplorable state, although scarcely so bad as last season, when my own, with the exception of Up-to-Date, were a complete failure. The ground has been under culture five years, the first two producing good results. During the whole period I have made numerous experiments, growing in 1898 over fifty varieties, and testing numerous and various manures, the last two seasons depending upon artificial manure. The soil is sandy loam, with the birching tendency of clay. The soil was thoroughly basted trenched, a good coating of manure being placed on the lower spit after breaking up. The soil lay fallow throughout the winter, and was turned lightly in March. The furrows were made April 1st, a sprinkling of superphosphate, kainit, and nitrate added when they were completed. Seed was planted April 15th, Ringleader being the earliest to lift, mid-July, followed by Centonny. Both of these have given very fair results, but not equal to Ideal, which I am at present using. One thing that baffles me is the non-decay of many of the seed tubers planted. Such a seed may produce plenty of healthy haulm, yet when lifted only one or two small tubers are visible, whereas another plant in the same row may produce twenty to thirty tubers, the seed in this case being totally rotten. Potato scab, referred to by "T. Fowler Ward," page 316, has appeared for the first time this season. Sandy soil is considered to foster scab; but why has it not appeared before? That time, or want of it, is the cause, is scarcely creditable, as I dressed a part of my soil with lime after trenching. The soil contains no rough substances or anything liable to promote fungoid growth. However, compared with Potato disease, scab is a minor detail, and I consider my immunity from it due to thorough trenching, plenty of space between the rows, and well firming the soil when earthing, taking especial care to make the ridges as pointed as possible to prevent furrows on the ridges, which I am inclined to believe materially help the disease.

KENT

NOTES AND REPLIES.

Parsley.—We often find a dearth of this herb, especially from February onwards, when a little more forethought and attention given to it this month would have put matters right. Breadths of early spring sowing should be all cut back about the middle of this month, excepting the few centre leaves, then scatter a little soot or artificial manure between the rows, hoeing the same in, when fresh growth will soon push up, and by November the ground will again be covered with fine leaves that ought to carry the supply on until the new year. Sowings made at the end of June or middle of July should be thinned out 6 inches apart, and the thinnings transplanted to a warm south border or any sheltered nook where a two or three light frame can be placed over them as soon as hard weather threatens. Often plants put out at the foot of a south wall will pass the winter safely if during the severest weather a little straw or Bracken be scattered over the plants, or a few dozen plants may be set out on the border of an unheated orchard house, where they can be protected from the cold cutting winds, which do quite as much mischief as do hard frosts. In transplanting Parsley much better results follow if the taproot is kept intact, similar to Lettuce, Beetroot, etc. Slugs will at times play havoc with it in a young state, when apply lime and soot.

Seakale (M. T.).—The "gardener," so-called, who is no better informed on the subject of Seakale than is apparent by your letter, should obtain a few lessons in growing it. Seakale is only used as an article of food early in the year, and when subjected to forcing. What is known as forcing-crowns should be not less than 1 inch in diameter and 8 inches long. These crowns are set close in a bed of earth, generally supported by boards of nearly 1 foot deep, and, being of convenient size, are covered up with boards and then thickly covered with the long straw from stable manure. In this way a gentle warmth is generated, and the "Kale" growing quickly, is of a tender, succulent nature, and blanches like Celery, by reason of the darkness. When a few inches long, and prior to the flower appearing in the point, the Kale is cut, the growths then being from 5 inches to 8 inches long. It is cooked and served with white sauce. The same condition of growth is brought about by the use of Seakale pots—i.e., large earthen pots for covering up the crowns in the open beds, the pots again being covered with long litter from the stable, as before. This latter is the most convenient way for amateurs and others requiring a small quantity, the first-named method being that employed in market-gardens where this vegetable is grown largely. You surely must have seen the bundles of the Kale exposed for sale in the greengrocers' shops in spring. The purple leafage is not used, but should be encouraged to develop for the benefit of the crowns. Small quantities may be forced in a box kept dark under greenhouse stage or in a warm cellar, the principle being much the same as forcing Rhubarb early in the year.

KENT UNIVERSITY OF ILLINOIS AT URBANA-CHAMPAIGN

PLANTS AND FLOWERS.

OUTDOOR PLANTS.

FLOWER BORDERS, COLOURS IN.

I SEE in a recent issue a letter from "Slow Coach," which interests me much, as I had just the same idea—i.e., to keep the colours in my flower borders distinct. I venture to think that my small efforts in this direction, and that a list of the flowers which I found made a good succession (and that is the difficulty, to keep up the supply without gaps) may be of some slight use. I began last autumn, and prepared the way by removing or eradicating until I nearly succeeded in keeping the colours apart. The blue bed has been the best one. I think, for certainly blue flowers do not contrast very well with other tints, but when massed together the many varying shades of the colour are most enchanting. In your reply to "Slow Coach," I understand you to speak of the Iris as suitable for the blue border. Now I must say I should never admit any Irises among the blues; their place surely is with the lilacs and purples. To begin, therefore, with the blue border. Earliest of all came the Scillas, a row edging the border (April), then a thick border of Forget-me-nots (May), followed by Veronica prostrata (June). These, of course, were planted the previous autumn. Also big clumps of Anchusa semperflorens and a low-growing Bugloss. I sowed a broad stretch of Nomophila late in March and at intervals during the following four or five weeks. This ensured a long period of flowering, and the result was a turquoise blue carpet for several weeks, which is only just over. Lobelias, planted in wherever a gap could be found in June, have taken its place. This border is five or six feet wide, in front of a brick wall about 50 feet long, and faces west. At the back, close to the wall, were planted two rows of Delphiniums, about thirty, in shades of true blue, from pale turquoise to deep French blue (all the purple and bronze metallic shades are in the purple border). These formed a good background, and were at their best in July. Between and in front of them are groups of the lovely Salvia patens (August) and of tall-growing Veronicas (July), two or three sorts, Commelina (August), Borege, and Bavarian Gentian (August). Phacelia campanularia (July) was a failure: only an odd plant or two came up and flowered. It is my despair; I cannot succeed, try as I can. Sown in pots or in the open ground, early or late, the result was the same. It would, indeed, be an addition to any blue border. I must not omit to mention the glorious giant Anchusa italica (July) which, when grown as I saw it this summer in a Gloucestershire garden, is such a glory in blue. The blue Lord Anson's Pea is still flowering, as it has done for nearly two months, and has taken the place of the Delphiniums. Then there are Gentians to be thought of. I have none, but they are the ideal edging for a blue border. I must not take up too much of your space, and will just run through the names of the flowers I have found useful in the other beds. In the pink one, for instance, Rhodanthe Mauglesii, Schizanthus, Pyrethrums (May); Sweet Peas (the pink ones must be selected according to taste, Lord Kenyon, Oriental, and Gorgeous are all good), Valerian, Shirley Poppies, Campanula calycanthema, Sweet William, pink Spiræas (June and July); Pontstemons, Linum, Phlox, annual Asters, single and double, Sedum (the giant one), Perennial Phloxes, Godetias, pink Geraniums, and Fuchsias, planted out *ad lib.* (August and September). Of course Roses must not be forgotten.

LILACS AND PURPLES.

Pansies, Aubrietias (April, May), English Iris (July), Erigeron speciosus, Campanulas of several sorts (June and July), Lupinus, single and double annual Asters, the lilac and purple Sweet Peas—such as Fascination, Countess of Cadogan, Lady Radnor, Lady Grizel Hamilton—Schizanthus, Galega, Aster Amellus bessarabicus, Lavender (all in August), Statice, and all the beautiful tribe of Michaelmas Daisies for September and October. In the pink and lilac borders there are many

white flowers admitted, but none among the blue and yellow. The yellow I found the easiest to manage; it is also very attractive, always gay, and the reds and oranges of Nasturtiums, Montbretias tone well with the pure yellows. Dornicum, Crocus, Daffodils (April, May), Spanish Iris (June), Iceland Poppies (June), Calceolarias, Coreopsis, both annual and perennial. Tagetes, Yellowstrife, Nasturtiums (August), Helium striatum, Montbretias, Rudbeckia, (Ecnothera, Eschscholtzias, Helichrysum, Mimulus. Then all the coarser Sunflowers and such-like yellow Daisy flowers could have a place here if desired.

E. A.

SWEET PEAS.

THE attention which the Sweet Pea has received in recent years, is largely responsible for its popularity at the present time. While one will always highly esteem these flowers, no matter whether they be grown in a mixed

Sweet Peas. From a photograph by Mr. W. A. Smith, 154, Hagley Road, Birmingham.

row, or whether they be grown in clumps of named sorts, it cannot be denied that greater satisfaction is derived when named varieties may be gathered separately. There is always a tendency with mixed seed to sow much more liberally than is desirable in the best interests of the flower, and this is one of the reasons why named sorts of distinct colours are to be preferred. Now that named collections can be acquired so cheaply, the need for sowing rows of mixed seed is considerably reduced. A collection of twenty-four sorts is quite large enough for even a large grower of these flowers, and there are now so many charming colours represented in the Sweet Peas, that one may, with little trouble, acquire those sorts for which a special liking exists. There are rich cream or primrose, bluish, pink, rose, purple, crimson, orange-crimson, orange-pink, lavender, blue, and white, besides many other intermediate shades of colour, to say nothing of the striped or flaked sorts. For five shillings it is possible to obtain a collection

of about forty varieties. It will thus be seen that named sorts, and these, too, of the very best, are now brought within the reach of all. For general effect in the garden, sowing the seed in rows has always been the more popular method of culture, and it must be admitted that while the plants have continued to blossom, their display has indeed been very pleasing. As was mentioned earlier, there is a tendency to sow too thickly, and as a consequence the plants have failed earlier and the flowers have never been so fine as they might have been under a different method of culture. The illustration to-day represents the Sweet Pea doing remarkably well in rows. It will be noticed that the growth of the plants is much taller than is usually seen under these conditions; but this can only have been achieved by liberally manuring the soil, paying careful attention to watering, and, most important of all, gathering the expanded blossoms. If spent blossoms are allowed to remain, they quickly develop seed-pods, and immediately begin to deteriorate. While admitting the glorious effect of a series of rows of Sweet Peas in the garden, this cannot be compared with a series of clumps of plants, each of a given variety or colour. I sow five or six seeds in each clump, after first having deeply dug the soil and given it a heavy dressing of good manure. The results from this method of culture are very fine indeed. Better results still may be obtained by sowing five or six seeds in pots in the early spring, utilising a cold greenhouse or cold-frame for the purpose of raising the seedlings. The flowering quarters are prepared by deeply digging the soil, and previous to planting outdoors in late April, taking out the ground to the depth of 18 inches to 2 feet for each clump, and filling this three parts full with good manure. The ordinary garden soil is then filled in to the level, and the pots of plants, which must, of course, be carefully hardened off previous to planting outdoors, transplanted whole. When once the plants start to grow their progress is marked. My clumps are planted 3 feet apart, and I give them stakes about 9 feet in height. At the moment the plants are between 5 feet and 8 feet high, and their blossoms are large and handsome.

W. V. T.

NOTES AND REPLIES.

Wintering Carnation layers.—Should I run much risk if I let these out all the winter? I have about a thousand, and, of course, potted them all up in sets of the question. I want to know what are safe conditions, supposing the soil is fairly light and raised? The varieties mostly are Duchess of Fife, Sweetheart, Miss Audrey Campbell, Nox, Mrs. A. Tate, Czarina, and many other Selfs and Fancies. Would short manure, put in round the plants, be of use? Sparrows in the spring are a great nuisance, but I should try and remedy this with cotton and netting.—SELBORNE.

[In your high and dry district the plants should winter quite safely. Indeed, at Claremont, near you, many are bedded out early in October to stand the winter, the losses being very few indeed. The fancy kinds and Miss A. Campbell are the least hardy, and any kinds of which you may have doubt could be lifted and replanted in shallow boxes. It is overhead wet and a low-lying district that are most harmful to the plants—much more so than actual dry frost.]

Late Phloxes.—In autumn few flowers are more showy than the herbaceous Phloxes, and there is this advantage about them, they will grow almost anywhere where the soil is moist and deep. It is well known that they may be easily increased by division of roots in autumn and spring, or from cuttings of young shoots inserted in pots of sandy soil and placed in cold-frames. Here is a list of rather late-blooming sorts, some of which as I write these notes are just commencing to show colour: Progress, crimson; Zouave, magenta-carmine; Sesostris, amaranth; Fantome, violet, white centre; David Syme, rose, magenta eye; Aurore, salmon, purple centre; Sybil, purple, tinted white; Tamsie, light blue; Aurantiac superbus, vermilion; Gloire de Messin, carmine, crimson eye; Vesuvius, crimson-scarlet; and Bernice, pure white.—W. F. D.

Tritomas.—One of the most conspicuous of plants that bloom in the autumn is the Tritoma. It is often alluded to as the Red-hot-poker flower, but it was not until the

other day that I heard it designated as the "Long Distance" blossom, from the fact that to see its full beauty one should plant it where if distance does not "lend enchantment," it softens somewhat its bright colour. A green background, as a creeper-covered fence, or planted near to conifers, or amongst bell-growing plants, is where it shows best. Late in the autumn one may plant this favourite. —W. F. D.

Growing Edelweiss.—I would like to know all particulars about growing Edelweiss? I have some plants brought from Switzerland, and would like to know how to cultivate it? What soil ought it to have? Must it be planted in an exposed or sheltered spot? I have a rock garden in an exposed part of the garden facing south. Would Edelweiss grow there? The soil there, of course, is not by any means rich. Would it be difficult to grow in this part of the world?—SUNNY SOUTH.

[If your plants are nicely rooted there should not be much difficulty. If not, they may merely dwindle and die. The soil best suited is a rather poor or stony, and very gritty loam without manure—a pasture loam that has been laid up a year or more, and freely mingled with limestone chippings. This last, however, is not essential, and if you provide a good depth, say 12 inches or 18 inches of very gritty loam, selecting a spot on the rockery where the plants can be gently wedged between the

autumn. In setting the seed rake out quite deep cavities and fill with soil. It is a good plan to mix the seeds with damp soil—a paste-like mixture—and if the cavities are very dry rake them out a few days previously, and soak with water.]

Making Lily of the Valley bed.—Will you please be good enough to let me know in your answer column of GARDENING: When is the best time to make a new Lily of the Valley bed, how to make it, the best aspect, and number of crowns required per square yard? If made this year, will it bloom next spring?—B. F.

[The best time of the year is October and November, the best position a partly-shaded and moist one, and failing this a more shady spot. The crowns, if the bed is desired quickly to form a mass, may be 4 inches apart each way, or 6 inches will do quite well. A deep bed of rich, loamy soil, with a heavy layer of manure, worked in 9 inches deep is necessary. If you plant three-year-old crowns, these will flower next year, and if you wish this you had best purchase flowering crowns. "Crowns" are not, however, generally used, and clumps may be procured of which a third may flower the first year. Such as these would require much more room, even if broken up for planting. Perhaps the best kind for outdoor beds is one called "Victoria," and this

but not least, their washed-out looking colour that I find fault with. There are also never sufficient flowers open at any one time to create a show, neither do they stand erect so that they can be examined, but, on the contrary, have a bad habit of drooping which seriously detracts from their appearance. In my estimation this variety of *Arctotis* does not come up to the description sent out with it, and it would be interesting if others would give their experience of it in the columns of this journal. —A. W.

Plants for beds (*Inquirer, Drogheda*). —We think you would get the best permanent return by planting large central groups of Hybrid Tea Roses in the beds. A few good kinds are Mrs. Grant, Grace Darling, Marquise Litta, Mildred Grant, Madame Abel Chatenay, Lady Mary Fitzwilliam, Lady Buttersea, L'Innocence, Captain Christy, Madame Pernet Ducher. These are free and vigorous, and produce a beautiful lot of flowers. The plants would require to be 2 feet or 2½ feet apart. In the centre of each bed plant six bulbs of *Lilium candidum*. Between the Roses plant clumps of Narcissi, such as Sir Watkin, Emperor, Horsfield, Princeps, ornatus, Stella. As a margin to the Roses, plant old Clove, Ruby Castle, Alice Ayres, or any good free Carnation, and finally border with any of the Tufted Pansies. If you have sufficient of the Anemones, these may take the place of some of the Narcissi, but you should reserve ornatus as a good thing in such a mixture. This arrangement would give you flowers over a long period, and in recommending them we have in mind the fact that the outlay is at the beginning, and that the plants increase in beauty each year. The Roses would cost about from 1s. 6d. to 2s. each, the Carnations about 5s. per dozen, and the bulbs, taken on the average, 5s. per 100. The other things are very cheap. Indeed, by consulting our advertising columns you will observe how the prices vary for the same article. At the same time it is not economy to plant little bits of plants, and a good plant is generally cheap and satisfactory because a time-saver.

Omphalodes linifolia.—This annual is rather uncommon in gardens, though why I am unable to say, because it is well worthy of cultivation, and is most effective when judiciously employed. Perhaps the fact of its being so easy to grow is one of the reasons why it meets with such scant recognition. Unlike some annuals it remains in flower over a long period. With me the plants commenced flowering at the end of June and have only just ceased, and would no doubt have lasted much longer were it not for the heavy rains experienced of late. I grow it in clumps about eighteen across in the front of the herbaceous borders, and these groups are very telling when in full bloom, the silvery foliage and the small pure white flowers rendering them objects of great beauty. I sowed the seed in April and thin out severely as soon as the best and strongest plants can be distinguished, leaving about nine in a clump. All the after attention they require is a few stakes—or, what is still better, some "spray" taken out of a birch broom—to support them, and to afford water during dry weather. This does not by any means exhaust all the good qualities of this beautiful annual, as I have put it to another use this season, and many will no doubt profit by the hint if they have not already proved its usefulness in this direction. This is to employ it as a setting for Sweet Peas, Shirley and Iceland Poppies for dinner table decorations. Nearly everybody I suppose is aware of the value of *Gypsophila* for this purpose, and when it is stated that *Omphalodes linifolia* rivals it, for the reason that when so employed it is equally as light and graceful, further commendation is unnecessary. So pleased am I with it when used in conjunction with the flowers alluded to, that I intend to grow a few rows of it specially for cutting another season. The plant seeds most freely, so that once a stock has been obtained there is no difficulty in securing an ample supply for each season, if the plants are drawn and dried after they cease flowering, when the seed can be rubbed out at any convenient opportunity. I had a difficulty in obtaining it, and as far as I am aware only one of our seedsmen list it. —A. W.

Bud of Rose Anna Ollivier. (See page 398.)

is often sold at so much per square yard as lifted, when the purchaser can utilise it as he thinks fit. It is, however, a good as well as economical way of making a new bed, especially if this latter is at all extensive.]

Hollyhocks.—The season now passing has been an exceptionally good one for Hollyhocks. The nasty fungus which habitually preys on the stems and leaves, doing so much injury, seems to be far more harmful in hot, dry weather than in wet weather. No doubt the cooler air and abundant moisture render cool-loving plants like Hollyhocks all the more capable of resisting the fungus, as it at the same time weakens the power of the fungus to spread. Then it is now so universally the rule to raise plants from seed rather than from cuttings or suckers that they have more vigour in them than plants have that have been raised by the latter methods. Still further, seed strains now are of such high excellence. Too often the plants are put out to flower in mixed borders where the soil is already eaten up by shrub and hardy plant roots, and under such conditions fine growth and flowers cannot be looked for. Before planting in such places holes 12 inches over should be opened, some half-decayed manure put in, then that well mixed with the ground. Then Hollyhocks have some chance. In all cases they well repay for good culture. Seed may be sown now in shallow pans or boxes and kept under glass. The seedlings will be strong to dibble out in March, and should then carry good stems and blooms in the following autumn. I have lately seen grand double Hollyhocks raised from seed sown in warmth the preceding February. But it is not possible for amateurs to treat them in that way, and the best course is to raise from seed now, and winter them. —A. D.

Arctotis grandis.—I do not know what experience other growers have met with in the cultivation of this hardy annual, but mine is certainly not a very encouraging one. I purchased a packet of seed in the spring and raised quite a nice lot of plants, which were planted out in due course in a mixed border. At the present time they are of considerable dimensions and produce plenty of flowers, but it is with the peculiar way they have of unfolding, the short time that they last, and last,

stones, planting quite firmly, we see no reason for failure. The plant is quite easily raised from seeds, and is most successful in those districts where sandstone rock prevails.]

Wall gardening.—I am planting the joints of an old stone wall, forming a kind of sunk fence, and wish to know if the autumn or spring is the best time for sowing the seeds of such things as the following: Alpine Poppies, dwarf Campanulas, *Frimus alpinus*, *Linaria alpina*, *Linaria Cymbalaria*, *Antirrhinum*, Maiden Pinks, Wallflowers, the Cheddar Pink, and the like? I sowed many of these last spring, but very few have come up.—C. M. W.

[Generally speaking, the autumn and winter months are best, simply because the amount of atmospheric moisture is then greater. Success or failure, however, is more largely dependent on the amount of moisture reaching the wall itself than on the time the work is performed. For example, a rough stone or brick wall, where ample crevices abound, may be successfully planted at any time, while a well-built wall that affords few opportunities for moisture getting into the joints, may be planted again and again without success. Again, a wall facing south-west, that catches somewhat of the besting rains, is far more quickly clothed than a north or north-east wall, and so on. In all probability the spring-sown seeds may germinate this autumn: we had an identical experience only last year, the seeds remaining dormant all the summer, and germinating like Cross in

ROSES.

ROSE BUDS.

It may be said with much truth that all Roses have pretty buds, but when the collection is searched for varieties yielding really handsome-shaped buds, the selection then becomes much modified. As a rule, an elongated bud, and

it will be grown by the acre presently) is Liberty. Imagine a bud or half-open flower of Alfred K. Williams, and we have a good idea of Liberty. This brilliancy of colour, combined with the ever-blooming quality of the best Hybrid Teas and also a sweet perfume, are excellent traits in a most charming Rose. Other brilliant reds, scarlets, and maroons, are: Fisher Holmes, General Jacqueminot,

what is more lovely than the old pink Moss: One is apt to obtain a poor conception of the beauty of this Rose from the faded branches hawked about the streets, but see it on the plant on a June morning and I doubt if a lovelier Rose could be gathered at the same time. All the Mosses are pretty in bud, the white Bath, with its paper-white petals and mossy encasement, and the Crested Moss, with the curious Parsley-like outer covering, being two good companions for the old pink. There are four pink Roses among the Hybrid Teas that deserve extensive culture as bud varieties. These are: Madame Abel Chatenay, Mrs. W. J. Grant, Killarney, and Madame Jules Grolez. The first-named is now cultivated in the fields as a market Rose, and I do not wonder at this, for a more exquisite bud is not to be found in the whole collection of cultivated kinds. The other three are so well known that I need not enlarge here on their merits. I might say, however, that if space is available, a row of the climbing form of Mrs. W. J. Grant will give untold pleasure to the cultivator. A trellis some 6 feet high would be the best support, or stout poles would do as well. Plant three feet apart. We have had as many as sixty buds on one plant at one time this season. In conclusion, I must not omit from pink Roses Mrs. John Laing, Madame Lambard, and Lady Battersea—the two latter border, perhaps, more on the reds, but their exquisite buds entitle them to mention in this article. ROSA.

Buds of Rose Alfred Carriere.

this, too, of moderate size, is preferred for a button-hole, but it is not unusual in the Rose season to see huge show blooms, such as Maman Cochet, worn as a coat flower. The ideal Rose-bud is unquestionably Catharino Mermet, the beautiful sports of this fine Rose, namely, The Bride and Bridesmaid, sharing the honours equally with their parent. Another exquisite Tea Rose is Non. Edith Gifford. It will be seen from the illustration (what handsome formed buds and blossoms this most useful variety will produce, and it has no compeer of its colour. The long pointed buds of the old favourite Niphotos are as yet unsurpassed for snowy purity. It is really surprising how successfully this somewhat tender Rose can be grown, as evidenced by the notes in GARDENING for July 19. Where a high, sunny wall is available what could be more useful than a covering of Climbing Niphotos? Or if an isolated standard be wanted, this climbing form is perfect for the purpose. I need not say how valuable this Rose is under glass, the dwarf form being, perhaps, the more useful, although to all who possess a lofty greenhouse I would commend the climber, either on the wall or roof or as a standard in a pot. The umbrella-like head of the latter when well developed is a perfect picture. A charming flesh-white, rampant grower has come much to the front lately. I allude to Mme. Alfred Carriere. Very pretty buds may be freely culled from this Rose, whether it be grown on a standard, which will half fill a cottager's front garden, as I saw it recently, or from a wall, which it will soon clothe with a beautiful refreshing green growth.

Perhaps it will be helpful if I group the various kinds in their colours, and before I leave the white and blush group I should mention the following as being in every way worthy of cultivation for their comely buds: Souvenir de la Malmaison, Kaiserin Augusta Victoria, and its rampant climbing form for a lofty south or west wall; Innocente Pirola, White Maman Cochet, Gloire Lyonnaise, Purity, and Souvenir du President Carnot. As a contrast to a bed of the white and flesh-tinted kinds what could be more effective than rich crimsons? One of the best (and I believe

Papa Gontier, Victor Hugo, Prince Camillo de Rohan, Prince Arthur, a rose identical with an older kind, Triomphe de Caen, Gloire de Margottin, Duchess of Bedford, Duke of Edinburgh, and Ulrich Brunner. For really good perpetual flowering qualities I should place Gruss an Teplitz next to Liberty as the most useful scarlet-crimson we have, although individually its buds will not compare with Victor Hugo. Yet another good contrasting bed to the last would be one of yellows of various shades. Of pale cream colours Madame Hoste and Marie Van Houtte are the best. A host yellow is found in Madame Chedaune Ginoisseau, and a variety not yet much known, Alliance Franco-Russe, gives handsome, double buds that surpass Perle des Jardins outdoors. One cannot exclude Marechal Niel, and in

some gardens it is a great success. To those who have hitherto failed with the variety I would recommend them to grow it in bush form in a long row. Prune back the new wood rather moderately and spur in small wood. Mulch the ground with lawn mowings or some clean material, as the buds hang underneath the foliage and nearly touch the ground. From a row of plants of this description a quantity of most beautiful buds may be cut. I would plant in the kitchen garden, for the bushes are not by any means decorative. Rich golden-yellows and apricot colours are: Madame Ravary, Billiard and Barré, Madame Pierre Cochet, Bouquet d'Or, W. A. Richardson, and Madame Berard—the two latter on a wall, the others as bushes—although these two may be grown in the latter form if provided with ample room.

Of pink Roses there are numerous kinds, and

NOTES AND REPLIES.

Climbing Roses for wood fence.—I wish to plant climbing Roses this autumn against a wood fence (strong match-boarding), 8 feet high, and about 15 feet long, aspect S.S.W. Sun on fence rather obscured by tree at one end, and by shadow of house, but has effect for about three hours (mid-day). What climbers would do best, and how many should I plant?—M. E. C. Ross.

[Although your fence is somewhat shaded, you should be able to grow very successfully the following beautiful kinds, these five being sufficient for the length at your disposal—Wm. Allen Richardson, Dr. Rouges, Mme. Berard, Climbing Belle Siebrecht, and Mme. Alfred Carriere. Be very careful to prepare the ground well by deep digging, and see that the plants do not suffer from want of water next season, but when you do water them let the amount given be ample.]

Hybrid Teas as standards (*T. nivalis*).—We can recommend the following as being all first-rate kinds—the first six are vigorous growers, the following ten are medium, and the last two rather diminutive and should only be grown as half standards: Admiral Dewey, a lovely blush white sport of Caroline Testout; Billiard and Barré, one of the best golden-yellow Roses grown; Gladys Harkness, like a high coloured Caroline Testout; Ferdinand d'Amn, rosy-carmine with salmon shading; Mme. Viger, pale rose, reverse of petals silvery-white; Mme. Wagram, satin rose, a bold,

Moss Rose bud.

handsome flower; Bessie Brown, growth as vigorous as in Viscountess Folkestone, colour creamy-white, large, but it has the bad habit of drooping; Killarney, flesh pink and white, lovely elongated flower; Liberty, brilliant crimson, perfect shape, medium size, sweetly fragrant; L'Innocence, pure white, beautiful

form; Mme. Eugénie Bouquet, yellow, shaded with carmine, exquisite colour; Mme. Jules Grégoire, satin rose, very bright and pleasing colour, and most shapely blossoms and buds, foliage of happy contrast; Mme. Ravary, golden-yellow, lovely buds produced on stiff shoots; Souvenir de Mme. E. Cauvin, rosy-flesh, shaded with yellow and orange; Souvenir du Président Carnot, rosy-flesh shaded, with very elegant buds; Violoniste Emile Leveque, rosy-flesh, shaded yellow; Tennyson, pearly white, exquisitely formed; Marie Louise Poirer, tender rose colour, a most fragrant Rose. There are some splendid new Roses of this year, but as we presume they would not be attainable in standard and half standard form, we omit to name them.

Roses for N.E. wall.—I am desirous of covering a wall, from 15 feet to 25 feet high, and facing N.E., with Climbing Roses (Hybrid Teas, Teas, and Noisettes). Would you be kind enough to mention in GARDENING the names of a dozen that would be hardy in such a situation?—*J. S. GROSE.*

(In your county (Devonshire) many Roses would flourish on such a wall that could not be planted in the colder counties. The following would afford satisfaction: Celine Forestier, M. Allen Richardson, Chesbunt Hybrid, Noire de Dijon, Climbing Captain Christy, Kaiserin Friedrich, Mme. Alfred Carriere, Mme. Gerard, Mme. Jules Siegfried, Reine Marie Marguerite, Noella Nabonnand, Revo d'Or. We have a high opinion of England's Glory, a large, pink flower in the way of Caroline Testout, of a good grower, but as it is new, probably only small plants are yet available; but next season it should be plentiful.]

Rambler Roses for bank (H. C. Johnston).—Nothing would look more beautiful than some of the Rambler Roses allowed to grow freely for planting in the large bed on bank. It is one of the prettiest sights of our country hedgerows to see a wild Brier sending out its long arching growths, all bespangled with the blush-pink, delicately fragrant blossoms, and so it is with the Crimson Rambler. I have often had growths upon this rose when bending over produce quite two dozen trusses of blossom. They require a lot of space to see them to the best advantage. Some pink or white or both should, I think, be mixed to tone down the garishness of the Crimson Rambler, and for this purpose good ones would be Flora and Queen Alexandra, the white, Félicité-Perpetue and Bennet's Wedding. These would all flower simultaneously. If you cared to lengthen the season on this bed would be in blossom, you might mix with varieties that blossom a week or two earlier than the kinds named, and for these select of Hybrid Sweet Briars Anne of Austria and Amy Robsart, also The Dawson Rose, Macrantha, Una, Electra, and Mrs. Anthony Waterer. Treat them all alike, giving their growths perfect freedom, only cutting away old wood, and you will have a charming display.—*ROSA.*

Rose Crimson Rambler on house walls.—The Crimson Rambler Rose growing up the house last year on a wire trellis. The Rose does not thrive on a wall and an expert informed me it would not grow well against the galvanised wire. Is this right, and would you, if so, obviate it? I should be obliged if you could give me the names of one or two strong growing, climbing Roses for a north-west aspect, a good one preferred? I notice you have mentioned Revo d'Or in one or two recent issues as a strong climber. Would you recommend that? This is a locality where the spring is late effect.—*TRAVAN'S BELL.*

[We have repeatedly advised our readers not to plant this Rose against hot walls. The variety objects to the position, and is badly affected with red spider when so grown, which gives the foliage the rusty appearance, so different from its true grass-green tint. We do not object if painting the galvanised wire would have any beneficial effect. What it requires is free circulation of air among its foliage, and unless you could provide this by placing the trellis a foot or so away from the wall, we should advise you to replant the Rambler against a pillar, either in the herbaceous border, for which it is admirably suited, or railing over arch, old tree stump, or some such position. If you desire a brilliant scarlet wall Rose try Climbing Cramoisie Supérieure, or, for a moderately high wall, Gruss an Teplitz. We should certainly recommend Revo d'Or for a yellow climber—it is the best we possess. For other good hardy wall Roses, see list recommended to "J. S. Grose."]]

CHRYSANTHEMUMS.

NOTES ON CHRYSANTHEMUMS.

During August and the beginning of September it will be found in most cases that a bud will appear at the point of the main shoots, and immediately under, a series of growths will make their appearance from the axils of the leaves. This is termed the crown bud, and is what most exhibitors retain, cutting off all the shoots below, thereby conserving all the energy in the bud selected, producing in time a magnificent bloom some 12 inches to 15 inches across, and of great depth. For decoration, however, let all the shoots which appear develop; these shoots when they have attained a certain length produce in their turn, this time a cluster of buds called terminals, because it is the termination of the plants' growth, all energy being now wholly confined to building up the flowers. If severe frost puts in an appearance,

tend to sour the soil, and probably destroy the plant in the end. When all the plants are under cover it is advisable to fumigate or vaporise the house thoroughly, it being always well to start with a clean bill of health. A disease pretty prevalent after housing is mildew, this making the plants sickly and weak, and looking anything but well if you are presenting a bunch of blooms to a friend. Careful ventilation and watering are good preventives, watering only when the plant requires it, and opening the ventilators on the lee sides only if the wind is high. No strong wind should be allowed to play among the foliage, so that ventilation has to be carefully watched. The disease known as "spot" affects the plants sometimes, and may be caused by the ventilation also, as well as giving stimulants too often and too strong. Mildew may be cared by dusting sulphur on the plants, but if only one plant is affected it is the better plan to remove it.

Bridge-of-Weir, N.B. D. G. McIVER.

Buds of Rose Edith Gifford.

the plants should be got under cover with the least possible delay. In some places they will need to be housed earlier, a great deal depending on the weather. It is always advisable to let them stay out as long as possible with safety, but on no account let the buds show colour before doing so. When housing, cleanliness should be the aim. The house intended to receive the plants should be well washed with soap and warm water, woodwork, glasswork, and ironwork alike receiving attention. All pots should be washed before taking them inside, arranging the Japanese varieties, if possible, at the warmer end of the house, as they will stand a few more degrees of heat than the incurved. Of course no heat, or very little, will be required at this stage. It is always well, as a rule, never to give plants stimulants for the first eight or ten days after housing, as, owing to the change from outside to inside, the roots are almost at a standstill. Stimulants, therefore, at this time would only

NOTES AND REPLIES.

A good early flowering Chrysanthemum.—Amongst early flowering Pompons we get many Chrysanthemums that are extremely dwarf, flower early, and are quite hardy. St. Croix belongs to this number. It is only 18 inches in height, is of a bushy habit, and bears numerous soft pink blossoms. I have it in bloom now (September 10), and as it is quite hardy, having been outdoors all last winter with only a covering of straw, I can say a good word for it where very dwarf plants are wanted. It is just the sort for a window-box or small pots.—*TOWNSMAN.*

Seasonable hints.—At this season readers are often in doubt regarding the question of bud selection. All types, no matter what the names of the different varieties, should have their buds retained. Some growers may raise the question of whether the buds should be first grown, second crown, or

terminal. The kind of bud to be retained at the present time and from this time forth need not be defined. Any bulb showing on the plant should be retained, no matter what their definition may be. When retaining the bud do not rub out or pinch off at one time all the shoots or smaller buds surrounding it. This is too great a check upon the plant. It is better to pinch off one shoot each day until in the end the retained bud is found to be quite alone at the apex of the shoot. It is then retained, and the grower's chief concern for the future should be to see to the bud's proper development. See that the shoots are secured in an upright position and are protected against damage from strong winds. Once the bud is nicely set and is moving, feeding may be followed with advantage. Soot-water, varied with occasional doses of reliable manure-water, should be given, increasing the strength of the latter very gradually. Many of the prepared concentrated manures are excellent for use by amateurs.—E. G.

Early-flowering Chrysanthemums.

—I have before me a list of Chrysanthemums, published in 1886, in which some two or three dozen early-flowering varieties were given prominence. The Japanese and Pompon kinds were about equally represented at that time, but of the former, not more than three or four sorts are to be met with to-day, and even then in a very limited degree. Mons. Pynaert van Geert, a yellow, striped red, was very highly thought of, and for some years was seen at the early show of the N.C.S. Another of the quartette is Madame Castex Desgranges, the early white Japanese, which has probably been more largely grown for market than any other white in commerce. It has not yet been ousted from the garden, but its days, or rather years, are numbered, in view of the many good things now being largely grown. Alexander Dufour, a bright rosy-purple, is another of the four Japanese sorts alluded to. For years Mr. Norman Davis used to grow a large group of this sort at Camberwell, and until quite recently it was very highly regarded. La Virgo is the remaining variety, and this is a pretty white kind, very dwarf and free-flowering. A certain section of growers is desirous of classing this flower as a Pompon, but it is a mistake to think of so doing. The newer race of early Chrysanthemums, of which a large batch came from France ten to twelve years ago, has almost eclipsed those introduced earlier, and now that English raisers are giving us many sorts of dainty form and beautiful habit, the change is becoming all the more complete. The near future will see our hardy flower-garden completely transformed in the autumn, by the aid of the increasingly augmented list of beautiful sorts.—E. G.

INDOOR PLANTS.

HEATING GREENHOUSE.

(REPLY TO "OLD SUBSCRIBER.")

We take some of the more pointed questions, and answer them offhand. Can you use a 4-inch flow and 3-inch return and expect to keep out frost? Yes. The action is always rendered sluggish thereby, however, simply because the larger amount of hot water, instead of coursing freely throughout the system as one uniform measure of circulation, becomes impeded or choked at the drop into return pipe, and causes semi-stagnation or a slow circulation generally. It is lessened or obviated altogether by a disproportionate fall in return pipe—i.e., a fall which inclines at a greater angle than that appearing in the rise in the flow pipe above. Hot-water pipes are infinitely better suited to heating when quite clear of the flow, 9 inches or so, as then all heat radiating from the pipes is employed to advantage within the house, and is not wasted, as must often ensue when the pipes are in close proximity to the floor. Not only is this the case, but, as a rule, there is, to bring this into effect, a sharp rise into flow not far from boiler, a fact alone that gives a good impetus to the general circulation. With these precautions and the pipes fixed high along the side, it is possible 3-inch pipes would keep out frost. Here, however, you must ever bear in mind that as you diminish the radiating sur-

face in the pipes, those remaining in the working will of necessity require to be heated to a much higher temperature to do the work. This alone has its drawbacks so far as plant culture is concerned, and the simplest and best system always is a fairly large number of pipes heated at a low temperature. Too many do exactly the opposite—viz., fix a minimum amount of piping, that must perforce be kept at a very high temperature to do the work. There is, of course, just as much in the management of fires and so on, and, indeed, the item of stoking is of very considerable import, and should be well studied by all who have greenhouses and the care of plants. In a case like yours, the best fuel is anthracite cobbles. No fuel provides so lasting and steady a heat, and, with discretion in the management of the fire and the time of making up for the night, it is easy to keep it going for ten or a dozen hours without attention. An essential in the use of this fuel, however, is a good brisk draught, which is easily arranged for if non-existent.

INCREASING DOUBLE BEGONIAS.

I HAVE a number of choice tuberous double Begonias grown under glass, which I am desirous of increasing. Would you kindly give me a few hints as to the method of procedure? 1st, by seed. Does this require fertilising—if so, how? 2nd, by cuttings. 3rd, by division of tubers. The proper season for each operation, with a few cultural directions, will be much appreciated.—H. J.

[Many of the finest double-flowered Begonias do not produce any pollen, hence, in order to obtain seed it is necessary to take the pollen from a semi-double flower and apply it to the female blooms of the best varieties, as all the female flowers are single, which you will see if you examine your plants. A camel's-hair brush is the best thing with which to transfer the pollen, and you will find it more plentiful on a bright day, after the sun has been shining for a couple of hours or so, than at any other time. To do this, however, it will be necessary to wait for another year, as even if the flowers are fertilised there will not be time for the seeds to ripen. Plants obtained in this way cannot all be depended upon to reproduce the very double flowers of their seed-bearing parent, hence, where double Begonias are raised in quantity from seed the young plants are all flowered in order to prove their worth before sending them out. Begonia seed should be sown in February, in a gentle heat—say, a temperature of 60 degs. to 70 degs. From its minute size more care is needed than in the case of many plants. The pots or pans for its reception should be quite clean and well drained, then filled to within half an inch of the rim with a mixture of two parts loam to two parts peat or leaf-mould and one part silver-sand, the whole well mixed together and passed through a sieve with a quarter-of-an-inch mesh. Being pressed down moderately firm and made level, this must be watered through a very fine rose, and while the soil is still moist the seed must be thinly sprinkled thereon. No covering of soil will be needed, but simply a pane of glass laid over the pot or pan till germination takes place, when it must be removed. Particular care is needed that the seed-pots do not get the direct rays of the sun. When the young plants are large enough to handle they must be pricked off into other pots, prepared the same as for sowing the seed. The next shift will be into small pots, and, after that, into larger ones, as required.

2, Begonias of this class can be propagated from cuttings; indeed, it is the method followed in nurseries for the increase of the finest forms. If a tuber when starting in the spring pushes up two or three shoots, all except one may be taken as cuttings. The best time is when they are about 2 inches long, and they should be taken off as close as possible to the tuber. Then insert singly into small, well-drained pots of sandy soil, and place in a close propagating case till rooted. Where there is only one shoot from a tuber the better way will be to leave it to get a little longer, so that in cutting it off one good eye may be allowed to remain for the future growth to spring from.

3, Division of tubers is carried out when the young shoots are from 1 inch to 2 inches long, as one can see exactly where to divide the tuber, which is best done with a sharp knife,

leaving, if possible, a good-sized piece of tuber to each stem. They are then potted in the ordinary way, keeping the piece of tuber at the base of the young shoot well below the surface of the soil, and treating just as growing tubers that have not been thus operated upon. This last method of propagation is, however, not much employed, as, in the first place, the majority of tubers only produce a single shoot, and, secondly, the cut portion of the tuber sometimes heals in an unsatisfactory manner.]

NOTES AND REPLIES.

Oleander flowers failing to open.—I should be obliged by your telling me what to do to my Oleander. It is growing in a tub and looks healthy, with three or four trusses of buds, but though these have been formed for some time no blossoms open. The plant is kept in a conservatory during the winter, and stood out-of-doors about the end of May. It is four years old.—B.

[Oleanders will occasionally behave as yours have done, some varieties being more liable to do so than others. The cause of it has given rise to a good deal of speculation, and it is generally considered to arise from the roots having received some check, particularly in being allowed to get too dry, for given thorough drainage the Oleander is quite a water-lover. In the case of some large old plants that had long been in the same pots, we advised giving a dose of weak liquid manure about once a fortnight, beginning just as the flower buds were seen, and the plants have given us a check of any kind.]

Ventilating a greenhouse.—I built a small greenhouse three months ago. It is 9 feet long, 5 feet wide, and 8 feet high. I have a 12-inch ventilator in the top, but no heating apparatus. The top windows draw steam during the night time. Could you kindly inform me, through the medium of your valuable paper, if the cause, also is it detrimental to the plants? If so, what remedy have I?—AMATEUR.

[The moisture that collects on the glass of your greenhouse is caused by the water used therein. Its density is to a certain extent regulated by the condition and temperature of the outside air. It is certainly not detrimental to the plants in the greenhouse; indeed, without atmospheric moisture they would be attacked by innumerable insect pests. Do you shut the ventilator of your house during the night? If so, it would, in an unheated structure, be much better to leave it always open till at least the end of September, so as to ensure the hardening off of the plants therein, the better to enable them to stand the coming winter.]

TREES AND SHRUBS.

Bignonia radicans does well on a south wall in the warmer parts of the country, and is this season flowering quite as freely as usual. Where the climate is suitable proper position can be accorded it. No chamber produces a more gorgeous effect during late August and early September.—A. W.

Lonicera hexocera.—This flowers towards the end of June, the blooms possessing the additional merit of being deliciously fragrant. This is also a good subject for training up the face of a wall, as it is a rapid grower and covers quickly. I had a specimen brought to me this season which covers a very large area of wall space and was, moreover, producing an abundance of flowers.

Jasminum humile.—This grows at a rapid rate and flowers abundantly on a wall having a south or western aspect, and is a charming companion to the common white Jasmine. It is not met with nearly so frequently as the latter and the naked-flowered Jasmine (*J. nudiflorum*), but why I cannot conceive, as it is hardy, for I have known it to survive frost of great severity in the west. The flowers are sweetly scented, and are produced during the summer months. It succeeds in ordinary garden soil.—W.

Spiraea Bumalda var. Anthony Waterer.—During the summer months the Spiraea gives a piece of colour quite its own in the shrub beds, and succeeds the many good spring and early blooming things, continuing in bloom over a long period. It has many merits, not the least is its dwarf habit, permitting it to be used in positions where taller growers cannot be admitted. I have it growing in the front of a mixed large shrub bed in which there are groups of herbaceous and tender plants. When this Spiraea is seen growing with Blue Delphiniums at the back, and has as its neighbours *Diplopappus chrysophyllus* and *Hydrangea paniculata*, the effect

is pleasing. Splendid results can be obtained by using this Spiræa and the other things named in beds alone, reserving places for Delphiniums, the best Michaelmas Daisies, Olearia Haasti, and things of a kindred nature, thereby giving more colour effect than is to be found in many of the arrangements produced by the use of tender plants.—J. CROOK.

FRUIT.

APRICOT MOORPARK.

This well-known Apricot is a great favourite where it succeeds, and may be classed as one of the best varieties grown owing to its size and excellent quality. The shoot illustrated shows how freely it crops in some localities. The fruits of the true Moorpark are large, very juicy, and richly coloured. It ripens on a south wall in August and on a west aspect early in September. The tree is a tree grower in its earlier stages. Gross wood should not be encouraged, as it often ends in canker if the knife is used too freely. Should the young trees make too much wood, lift in the early autumn in preference to pruning severely. In warm localities a south wall is not desirable, as it is too hot and often too dry for the Apricot. We have in warm soils seen splendid crops on an east wall; indeed, finer fruits than on the south wall. Old Apricot trees that have a hard border to root into do best. In soils deficient of lime it is well to give such aids as old mortar rubble or balk, making the border firm. The disease to which this variety is liable is difficult to combat, as the cankers die off suddenly when the tree is in a good condition, and these trees given ample attention suffer most, causing gaps at a time they cannot be made good. An old tree which escapes often lasts for many years. The only consolation is to keep a reserve of young trees to make good the losses. There are two distinct forms of Moorpark, one coming much earlier and with smaller fruit. This is the early Moorpark, an excellent Apricot, but lacking the size of the old variety. In this the fruits are rounder, more dotted with small crimson spots, and three weeks earlier.

and by that time most of the deep running roots should have been found, cut through, and the reserved parts taken care of. If this work is done in either bright weather or during the prevalence of cold drying winds, syringe the bared roots occasionally and keep them matted over as much as possible. All should be duly lightly pruned, the older ones, if very woody and bare of fibres, being also cut rather freely. Whether the same space as before shall be occupied with fresh soil should depend upon circumstances. The roots not being very long or worth preserving to a great length, then it may be possible to remake the border piecemeal. In any case renew the drainage if much clogged, and bring the roots up nearer the surface, distributing them thinly throughout the fresh soil. They will form fresh fibres more quickly, and most probably this autumn, if surrounded by a little of the best compost in a fine state, the burn-bake in particular coming into contact with them. The advice to make the new part of the border firm, especially adjoining the older part, is of vital importance. If the fresh compost is somewhat dry, give water in the course of three or four days, while in the case of outside borders pre-

some sharp sand. When shanking occurs, feeding rather promotes it, as, because roots are too deep, the feeding sours the soil. In any case you will probably find lifting and replanting, done just as the leaves fall, will correct the trouble.

Cracked Pears (Carnforth).—Your Williams' Bon Chrétien Pears are badly infected with the fungus, *Cladosporium dendriticum*. This comes chiefly when trees are old and the roots have gone deep into poor or sour subsoil. Your aim must be to either lift the tree, hard prune the deep-going roots, and replant it, or else, if the tree be too old, to open a deep trench round it, grub under, and cut off all the deep-going roots. Refill the trench, then fork off the top soil, replace with fresh, adding some well-decayed manure and bone-dust. So soon as you have gathered all the good Pears and destroyed the diseased ones, make up a solution of 1 lb. of copper sulphate dissolved in 25 gallons of water, and give the tree with that a good though gentle syringing. Also, so soon as possible, smother the tree, whilst damp, with freshly slacked lime. Only drastic treatment will produce a remedy.

Pears cracking.—I have lately taken a piece of ground in which there are several Pear-trees, and the majority of the fruit is cracked (and dropping), as per sample. Can you kindly inform me of the probable cause and cure?—J. W. M.

[Your Pear tree roots have, as is so commonly the case with old trees, gone deep into sour or poor subsoil, where they fail to find the requisite food with which to create sound fruit. That has led to the development of a fungus, *Cladosporium dendriticum*, which at once preys on imperfect fruit, causing cracks and black spots on them. If you could open deep, wide trenches round your trees 4 feet from the stems, cut off all roots clean at that distance, and find with a broad, sharp chisel on the end of a stout, long handle any downward roots, cutting them through, then filling in the trenches and well manuring the soil over the roots, the trees would soon greatly improve. Still, it would do them good if so soon as the leaves and fruits fall, all being collected and burnt, you could well spray the trees twice, at intervals of a fortnight, with the Bordeaux or sulphata of copper and lime mixture, the preparing of which we have so often previously described.]

Plum-trees falling.—I planted two dwarf-trained Plum-trees two years ago. I gave them a foundation of stones, then ashes, boxed them in with wood, giving them a little stable manure with the ordinary garden soil. This year there are a few Plums on each, but they are all cracked or bursting. Kindly tell me the reason, and state if I should lift them and replant them?—CARE.

[Your best course to bring good fruiting to your Victoria Plum-trees is to lift them so soon as the leaves fall. Trim the roots where any coarse ones have formed, and preserve all the small or fibrous roots, then cover them temporarily with soil until ready to replant. Take out all the stones and ashes below—wretched, starvation stuff—and the woodwork. Make holes 4 feet square and 18 inches deep. Throw the bottom soil on to one side, fill in with good top soil to within 6 inches of the top, tread it gently, then replant the trees, setting out the roots evenly. If with the good soil now placed on them you could mix some wood-ashes, old lime-refuse, and bone-dust, the results should be very helpful. You should then, in a year or two, get good fruit. A top-dressing of long manure laid over the roots so soon as planted till April and a fresh dressing in June will do great good.]

Twelve good Gooseberries (T. P. O.).—It is not possible to obtain a long season from Gooseberries naturally. Two or three ripen a few days earlier, but the bulk of varieties ripens all at once. The best way to have a fairly long season is to plant some flat-trained bushes against north walls, where, when the fruit ripen, if netted up, it will keep a long time. Failing that, if you cover up thickly with nets, or canvas, or mats, a few fall fruit-bushes, so as to exclude birds and rain, you can in that way have ripe fruits for some six weeks after all others are gathered. A good selection of dessert and cooking Gooseberries is: Early Sulphur, Early Red Hairy, Pitmaston Green Gage, Red Warrington, Langley Gage, and Whitesmith, of the first; and Whinham's Industry, Crown Bob, Lancashire Lad, Keep aske, Gunner, and Leader, of the latter. These are all nice to eat when ripe and are great

Apricot Moorpark.

PARTIALLY LIFTING VINES.

When the crops fail to ripen satisfactorily, shanking being very prevalent, and when also the wood ripens badly in spite of a free application of fire-heat, then it may safely be assumed that the root-action is much too deep and altogether faulty. Market growers who are not bound to have a full crop of Grapes every season in each house can afford to root out exhausted Vines and to form fresh borders at their rough and ready fashion for a fresh stock of young Vines. Private gardeners are differently situated, these leading it imperative to restore their old Vines to good health and a productive state without the loss of a season. As it happens, it is possible to do this effectively, the restored Vines sometimes fairly eclipsing much younger ones in wholly new borders. It is useless attempting these restorative measures without a good supply of fresh soil, not necessarily all turfy loam, though this is what most growers prefer. Failing a good heap of fresh loam, roughly chopped up, procure as much of this as possible and supplement it with the requisite quantity, of say to the extent of one-half of the bulk, or good garden soil. In either case add very little decayed manure, and "burn-bake" (the residue from a garden smother), wood-ashes, and half-inch bones freely. When this heap is ready, or at the same time that it is being prepared, commence searching out the roots of the Vines to be operated upon. Commence at the front of the border and gradually undermine till about two-thirds of the border has been forked over and wheeled away.

cautions will have to be taken against their becoming badly saturated later on. When Vines have been very roughly handled at the roots they are apt to flag badly when the sun shines. In extreme cases this should be prevented by shading them, but, as a rule, keeping the house rather close for a few days and syringing the foliage very frequently are all that is necessary. It is important that the old leaves be kept fresh as long as possible, root action being briskest in the autumn and while they last.

NOTES AND REPLIES.

Shanked Muscats (W. L.).—Your bunch of Muscat of Alexandria—if it be not Cannon Hill Muscat—shows shanking badly. It is noticeable that the small stems holding the berries to the bunch discolour, wither, and cause the berries either to fall or to discolour and become worthless. The trouble is generally due to root action. The roots have got into bad soil, remote from air and from food. Can you lift the roots? replanting them more shallow, and adding to the border fresh loam and a good proportion of good sifted lime-rubbish, and even

croppers. They are not classed as exhibition varieties, but the majority of those are mere bags of water.

Pot-Vines falling to fruit.—I bought six young fruiting Vine-canes last February—not one of them showed signs of bearing any fruit. They were all pruned and ready for starting when I bought them. I started them gradually about the 20th of February, and managed to keep a very moderate temperature all through. I would be much obliged if you will kindly point out to me why the fruit never appeared? I have an idea that the Vines received a check last year during the time they were ripening off. I may also add that mostly all the buds came very weakly, and a few of them never started at all.—G. S. E. B.

[We fear the fruiting canes or pot-Vines purchased by you last winter and placed in warmth in February last were too weak in growth to produce fruit. Good fruiting canes should be in 11-inch or 12-inch pots, and be as stout as a man's little finger to enable them to produce fruit. Then if cut back to about one fourth their length, stood on a shelf so as to bring the reds up near the glass, and be gently started until the heat is about 70 degs., they should each carry from six to eight bunches. A too common cause of failure in fruiting Vines is that they have been driven into growth in too great warmth, causing the formation of gross, soft roots rather than many hard fibrous roots. If yours were of that nature, then you were badly treated. We do not know what price you paid per Vine, but really good ones to fruit in the pots range from 7s. 6d. to 10s. 6d. each.]

Planting fruit-trees.—I went into occupation of new house in June last (own property), with garden at back, sloping gradually to south. Most of soil has been newly laid on, and house is a depth of several feet, all rich, black soil taken off. The subsoil is sandy. Will you kindly describe, through the medium of your interesting paper, all necessary preparation of ground for planting same with fruit-trees? The ground is at present planted with Winter Greens, which appear to be doing very well.—LONGRAMMA.

[Judging by the description you give as to the made up nature of the soil of your new garden, we conclude that it will not need trenching, but simply digging deep so as to well mix the surface. Before that is done, if you could give it a heavy dosing of lime or soot and also a dressing of wood ashes, great good would be done. But as you ought properly to plant all fruit trees in the autumn, or at the latest in November, it will be well to clear off the Winter Greens, as these will impoverish the soil. Don't add any fresh manure then, but apply a moderate top dressing about each tree or bush after planting to wash in. Always manure from the surface, later, as deep manuring attracts roots from the surface. Trees should be according to kind from 12 to 15 feet apart if standards, but much closer if dwarfs; Raspberries in rows 4 feet apart, and Gooseberries and Currants 6 feet apart each way. Don't plant anything too deep.]

Apple trees unhealthy.—I have an Apple tree in my orchard named "George Apple," which is apparently blighted or was struck by lightning. It is a valuable tree, and until this year has borne good crops. It threw out a good blossom last spring, but no fruit is on it now. The leaves are small, not up to usual size, and many of them are burnt at the end. The age of the tree is about forty or fifty years, but it showed no sign of decay until this year. The bark is shed almost completely round one of the principal boughs, but there is a small strip not yet dead on the part facing the ground. What is your opinion, and how will I treat it so as to save it if possible? On a good many young trees, some of them planted as long as five and seven years, there is a woolly growth, especially wherever a crack is to be found in the bark. Is it American-blight, and if so, what remedy do you suggest?—M. A. C.

[Your Apple-tree may have been struck by lightning, or it may be dying of old age or canker, but evidently it is dying fast, and so far as we gather from your description it is fast getting beyond saving. If, however, only a branch or two is dying, then have those cut off close to the main stem. So soon as the leaves fall coat over the surface cut with Stockholm tar to exclude rain. Very likely the decay is in the main stem, but has not yet made itself apparent. If that be so, grafting or any other operation will not save the tree from dying. Probably the best course would be to purchase another tree of a good variety, and plant it close by to take the place of the old one in time. The white woolly substance on your tree stems is American-blight. Get boiling water in which is infused a pound of soft-soap, and with the water as hot as possible well scrub out the insect. Then mix with clay some paraffin and soft-soap to make a paste, and paint that into the holes where the insects

GARDEN PESTS AND FRIENDS.

THE ASPARAGUS-BEETLE (CRIOCERIS ASPARAGI).

A PAMPHLET dealing with this pest has just been sent us by the Board of Agriculture, and, as we have received many inquiries about it lately, the following notes will, we trust, be useful to our readers:—

This beetle now and then does harm to Asparagus, especially in beds which have been established from one to three years, by eating and disfiguring the heads as they are formed, but chiefly later on by attacking the stems, of which they are particularly fond. In the larval and beetle stages the insects bite the tender Asparagus heads, making brown patches upon them, and cover them with a brown sticky fluid, emitted by the larvæ, defiling the heads also with masses of the sticky eggs, thus spoiling their appearance for market. Later on the beetles and larvæ eat the large round seeds, to which they are very partial. Plants may be completely hared of their foliage by a succession of broods of larvæ. The adult beetles now and then gnaw the shoots underground, and cause them to become bent and woody.

The Asparagus beetle is locally common in the southern and eastern parts of England; it is rarely found in the northern districts. Canon Fowler, in his *Coleoptera of the British Isles*, states that he does not know of a record from any locality further north than South Derbyshire. Enquiries made in 1899 failed to show its presence in the North of England or in Scotland. It is fairly widely distributed around London, and has been recorded as doing damage in Gloucestershire and Warwickshire. It is common in parts of Kent, but rare in Dorsetshire and the western counties. It is known in France, Germany, and Italy, and probably throughout Europe.

LIFE HISTORY.—The beetle is one-fifth to a quarter of an inch long. It is slender and graceful in form. Its body is shiny black, with a blue tinge; its head is black; its antennæ are dark brown; its thorax is red, with two or three black marks or lines upon it. The wing-cases have the outer margins of a pale yellow, and inner margins black, and there is a transverse bar of black across them; upon each wing-case there are three yellowish or lemon-yellowish spots or patches, which, with the transverse bar and the black margins, form the figure of a cross; hence the beetle is termed "Cross-bearer." These markings are very variable; sometimes the yellow spots are very small, at others very large. Eggs are laid from June onward, first upon the heads and shoots, and later upon the feathery foliage of the Asparagus-plants. The eggs are brown to dusky greenish-brown, and oval, being glued by their ends to the plants, usually in rows of three to five, but frequently they are placed singly, and occasionally in rows up to eight in number. They are usually covered with a thin, gummy coat, and are about one-sixteenth of an inch long. Larvæ come forth in from five to seven days, and immediately begin to feed upon the Asparagus. Chittenden says the egg stage lasts from three to eight days in America. The larval stage lasts ten to thirteen days. On reaching maturity the larvæ fall to the earth and undergo transformation just beneath its surface in a slight cocoon. The number of broods appears to depend upon the weather; in some seasons there are three, in others only two broods. Beetles and larvæ are frequently found upon the plants until the middle of October. The larvæ when full-fed is from two-fifths of an inch to nearly half an inch in length; in colour it varies from dirty greenish grey to dull slate; the skin is wrinkled, and each segment is provided with a pair of fleshy foot-like tubercles, except the first three, which are each provided with a pair of jointed feet; the head is black, and the tail segment has a distinct proleg. The colour varies very much, some grubs being almost yellow. They hold very firmly to the plant by means of the tubercles and anal proleg. They probably moult their skins three times, although only two moults have been observed. As soon as they have buried themselves under the soil they form a cocoon composed of frothy saliva, which hardens into a case of parchment-

like consistency of a dull yellow colour, which becomes covered externally with grains of earth. According to Lintner, some larvæ may conceal themselves beneath dead leaves or other material on the surface.

The pupa is pale yellowish in colour. Great Britain the pupal stage lasts from fifteen to twenty days. The beetle hatches three or four days before it makes its appearance above ground, so that the actual existence is shorter than it seems to be. Adults hibernate during winter. They are often found during the winter in the crevices under stones, bricks, and rubbish generally, also under the bark of trees and in the stalks.

EFFECT OF WEATHER ON THE EGGS, LARVÆ AND ADULTS.—In hot, dry weather many shrivel up, and the larvæ often fail to reach maturity. But during warm weather beetles breed more rapidly; nevertheless long period of hot, dry weather markedly affects their increase. Very cold weather affects the hibernating beetles, numbers are often being killed, particularly if warm cold spells of weather alternate.

NATURAL ENEMIES.—A few natural enemies help to keep down an excess of this beetle. The most important is the two-spotted ladybird (*Adalia bipunctata*), whose larvæ ("lady-birds") devour the eggs of the beetle. Adults have also been observed to eat the larvæ of the lace-wing-flies (*Chrysopa*), which are such ravenous green-fly eaters, attack the larvæ of the Asparagus-beetle.

AN ALLIED SPECIES.—A closely related one—the twelve-spotted Asparagus-beetle (*Crioceris duodecim punctata*, Linn.)—is also common upon Asparagus in Europe and America. Its larvæ living on the foliage and in the beds in colour it is orange red, each wing having six round black spots. It is apparently very rare, if not extinct, in Great Britain; it is more troublesome than the common Asparagus-beetle, a look-out should be kept for it by growers in this country.

MEANS OF PREVENTION AND REMEDY.—In the first stages of this attack—that is, when the beetles are feeding upon the juicy parts of the heads of the Asparagus as they are formed—it is difficult to deal with them, though during this period they do considerable harm, making the heads brown and spotty. It is desirable to leave a few heads uncut in the bed where there is infestation as traps for the beetles, which get up the feathery shoots and branches during the day for pairing and deposition of eggs. In the course of eight or nine days these plants should be cut off close to the ground and burnt. Another set of heads should be allowed to run to show which should also be similarly disposed of.

In America a method among prominent growers is to cut down all Asparagus plants in the spring so as to force the parent beetles to lay their eggs upon new shoots, which are then cut every few days before the eggs have time to hatch. Beds of young Asparagus plants are most liable to this attack in the first year or two, when only the strongest heads are cut for market, as the beetles like the succulent shoots of young plants. It would seriously injure the stocks in newly-made infested beds to cut off their shoots. In such cases it would be better to handpick the beds, killing the grubs and eggs between the fingers. Very finely powdered lime dusted on infested plants would also be efficacious, as it would adhere to the slimy bodies of the larvæ. The lime should be applied as soon as the larvæ are noticed, and the application repeated at intervals. In extensive beds the remedies to be employed are lining and trapping, as indicated above, by letting some heads grow into plants and brushing them off and burning them. Syringing can be adopted in gardens. Where Asparagus is grown upon a large scale this process is more difficult, as the plants are not set in rows, but it may be effected by means of knapsack spraying machines. Paraffin emulsion, consisting of 2 gallons of paraffin-oil and 1 lb. of soft-soap dissolved in a gallon of soft water, may be used for spraying purposes. The soap should be boiled, and while boiling the paraffin should be poured into it and churned up with the soap until it is thoroughly incorporated. The mixture should then be diluted with 1½ gallons to

gallons of soft water. Paris green is also a valuable remedy against these and other insects which feed upon foliage. It may be used at the rate of 1 lb. of Paris green to 20 gallons of water. Two pounds of fresh lime-stone be mixed with the Paris green. This mixture can also be put on with a knapsack machine. As this is poisonous, it should not be used till the Asparagus has all been cut. Laying should be carried out before the weather has become thick and strong. It may be necessary to repeat this operation, and it will be effective against both beetles and grubs. Poultry and ducks do not seem to eat Asparagus, but they readily devour grubs; and if kept in the garden, especially ducks, will probably do much good.

It would be desirable to examine the roots of Asparagus obtained for making new beds, as pupae or beetles may be conveyed in these. The United States infestation is extended widely in this way.

NOTES AND REPLIES.

Earwigs eating Nectarines (M. T.).—Would you not manage to fasten your muslin round the fruit so that the earwigs could not enter? If this be impossible the best thing you can do is to try and trap the earwigs by cutting the hollow stems of Beans or Sunflowers along the branches. Numbers may be caught sometimes by folding sackings, or some similar material, and laying it on the ground—in fact, just anything into which they can creep will hide make useful traps; they feed only at night, and generally try and hide themselves during the day.—G. S. S.

Lighted Celery.—My Celery is badly attacked by a bright (not Celery-fly). Is there any means of curing it?—H. M. A.

We assume that you mean to indicate that your Celery is attacked by aphids, which suck the sap from the stems and leaves. You should have no difficulty in getting rid of that pest if you will gently, when the weather is quiet, cut the infested parts with Tobacco powder, which you can purchase from a seedsman, and when rain washes it off, dust again. A couple of dustings should suffice to destroy the insects.

Geraniums injured.—Would you please be so kind to say what in your opinion has eaten the stems of the enclosed Geraniums?—A. S. L. C. A.

As far as I can see, the Geranium stems have not been attacked by any insect, but the injury has been caused by a fungus, which is not in a condition for me to name. It has in some places entirely destroyed the central tissues of the stems, leaving only the outer rind. This has caused them to wither and the bark to peel off in certain parts, giving the appearance of their having been eaten. Burn the infested stems.—G. S. S.]

Worms in manure.—I have about a ton of cow-manure, which has been kept about a year in a heap open to the weather. It now swarms with earthworms, and, as the manure is required for potting plants, I shall be glad if you can tell me how to destroy the worms before they get into the pots in the usual course?—B. L. N. O. R.

[The quantity of manure that you have is too great to treat with any liquid to destroy the worms. Could you spread it out anywhere where poultry or birds could pick it over? When using it for "pot work," could you not then pick the worms out, as it must then be handled in small quantities? If you wish to try some fluid, I should recommend lime-water.—G. S. S.]

Salvia injured.—I will be obliged if you will say in the next issue of paper what the insect is that devours my scarlet Salvia? I can see no caterpillar or grub, yet the Salvia planted by my herbaceous border are this year quite devoured.—M. E. D. R. L. H.

[I do not think the leaves of your Salvia have been attacked by any insect, but by a fungus. I do not speak very confidently on this point as I cannot find any direct trace of the pest, and some of the authorities on fungi deny that fungi are the cause of these holes and notches, but they are common on many leaves, and I have never been able to detect any insects, and feel certain they are not the culprits. Burn the infested leaves, and next year, if the disease appears again, at once spray with "Bordeaux-mixture" once a week as long as necessary.—G. S. S.]

Insect on Rose shoots.—On looking over my Rose-trees for likely shoots for cuttings I came across the enclosed insect, which was so perfect an imitation of the Rose shoot, to which it was firmly attached that I

actually took hold of it as a likely cutting. Please say what it is, and whether it is common, as I do not remember ever having seen it before?—R. V. L. C.

[This insect you found in your Rose-tree, which so resembled a dead twig, is the caterpillar of the Swallowtail-moth. These caterpillars are very common, but are comparatively seldom noticed on account of their extraordinary mimicry of dead twigs, the position which they assume when at rest, clinging to the branch merely by the legs at the extreme end of their bodies, and extending themselves at an angle to the branch, rendering them very difficult of detection.—G. S. S.]

Fungus on Rose-leaves.—I enclose some leaves of a climbing Rose which I have had for a long time against the south wall of the house. It is a fine pink Rose (I do not know the name), but it is of vigorous growth, and always flowers freely. During the last few years, immediately after flowering, the leaves have become yellow and spotted, like the enclosed specimens, and have fallen off, so that it looks very bare and ugly by the end of the season.—M. A. M.

[The leaves of your Rose are attacked by a fungus. Collect the diseased leaves and burn them. Next season, as soon as you see any signs of the fungus, spray the Rose with Bordeaux-mixture about once a week for three weeks.—G. S. S.]

Insect in garden.—I should be much obliged if you can tell me how to get rid of an insect which is destructive in my London garden. It is bright green, about a 1/2-inch long, and darts away so quickly that it escapes all applications of insecticide. It appears for a few weeks when the leaves are young, and ruins the tender shoots of Virginian Creeper, Jasmine, Ferns, etc., curling them up and stopping all growth. Is there any means of destroying the grubs in the winter?—M. S. C.

[From your description I imagine the insects infesting your plants are one of the "Frog-flies," "Cuckoo-flies," or "Jumpers." Some of the syringes which have a spray nozzle throw such a wide jet of spray that if suddenly and well-directed, using "paraffin emulsion," or some other insecticide, many should be caught by it; but a more certain way is to hold a large piece of board, sheet of canvas, or tin, newly painted or tarred, so that it is quite sticky, in such a way that when they are disturbed they may jump into it and be caught. These insects probably pass the winter in the egg condition, and where these are laid is uncertain. Spraying your creepers with a caustic wash in the course of the winter, taking care not to use it after the buds show any signs of starting into growth, would probably be useful.—G. S. S.]

GARDEN WORK.

Conservatory.—We are taking stock of our room under glass with a view to make the best arrangement for the winter. What is wanted is a continuity of bloom all the season, and this means looking a long way ahead. At the present there are the Chrysanthemums, which will last up till January, but we want something besides Chrysanthemums. We want variety, and this can be had only by growing quite a number of different things. There is a danger of drifting under glass into the same condition as we were thirty or more years ago with the bedding out in the flower garden. Then every border of old-fashioned flowers was cleared and converted into ribbon borders. Now many of us are getting back the old favourites, with any additions in the way of improvements to be obtained. The time, I think, is coming when the same course will be adopted with reference to the plants usually grown under glass. A house filled with Chrysanthemums is very bright, but it becomes monotonous. There are other things to be had, and a good batch of Zonal Geraniums is always effective. Heliotropes which have been pinched during summer will now be in bud ready to burst into blossom when a little warmth is applied. Some of the new varieties have very large flowers. Lord Roberts is a very fine variety with large trusses and bushy habit. The Scarborough Lily (Vallota purpurea) when well done is one of the brightest autumn-flowering bulbs. I remember the time when it was treated altogether as a stove bulb. Now it does better with open air treatment in summer, moving it indoors just as the flower-spikes are visible. Cyclamens when well grown make a very pretty group. The foliage of many of the seedlings is prettily marked, and the flowers much larger than we used to

have them, though very few have any fragrance now. The best way to deal with the bulb after flowering is to plant them out in light soil in a partially shaded spot, and lift them when they have made some growth. We lift ours early in September, and they make strong plants, but do not flower so early as the strongest seedlings.

Stove.—*Rodeletia speciosa* major is a very pretty, easily-grown plant, and makes a very useful exhibition plant for the summer shows. I have seen it in several winning collections this season; in fact, it has been in evidence every year for many years. It is one of the few old plants that still occupies its old position as a very useful stove plant. The flowers are useful for personal wear, or to fill specimen glasses, and it is seldom without flowers when the plants have attained some size. *Eucharis Lilies* in blossom should be plentiful now, with other plants coming on in succession. Heat and moisture will soon send up the flower spikes, which are specially useful for church decorations and wreath making. Years ago we used to grow a few aquatics in the stove, including one or two of the smaller Water Lilies, Villarsias, and other things. On a small scale for the amateur's house, a tub or barrel cut through the centre will make two rather interesting aquatic receptacles. The plants may either be grown in pots and plunged in the water, or be planted in a mound of good soil and pieces of sandstone. I have seen No. 1 pots used, with the bottoms puddled with clay. Anyway, a few water plants in small tubs or in some other way would be a source of interest, and the vapour arising from the water will be useful to other plants in the house. Weak liquid-manure may be given occasionally to *Gardenias* in bud, *Eucharis Lilies*, and *Poinsettias* which have filled their pots with roots. The nights have been cold lately, and warmth will improve all plants brought in from cool-houses, including the usual winter-flowering soft things.

Ferns and fine-foliated plants.—There is always a good demand for these in the autumn. It is astonishing the number of *Palms* sold in the country during the autumn. *Kentias* purchased now may be kept in a room in good condition all through the winter, or much longer; in fact, there is no limit to their existence if rightly managed. The watering and sponging are the principal attention required. In the winter very little water is required if the leaves are kept clean. During frosty weather the soil should be fairly dry, though, of course, there should always be enough moisture in the soil to keep the roots fresh and the foliage in sound condition. It will always be safe to keep to the sound test, and, when the pot gives off a very hollow sound, give water enough to moisten all the soil. The hardier kinds of *Dracenas*, *Indiarubbers*, *Grevilleas*, and *Aralias*, both the green and variegated, are useful indoors. The best Ferns for decorating, to stand wear and tear, are the *Pterises*, and the best of these are *Pteris cretica* major, *P. c. cristata*, *Pteris tremula*, *Phlebodium aureum*, *Cyrtomium falcatum*, and *Nephrolepis exaltata*. The last is one of the best basket plants. *Phlebodium aureum* also does well in a basket, but this is not quite so hardy as the *Pteris* family. It may be moved to the shady part of the conservatory in summer, but must have warmth in winter.

Hard-wooded plants.—These should now all be under cover, but their removal from the outside to the inside should be made as comfortable as possible, air being given freely night and day, and then needs for water duly studied. Where these plants are well cared for there will be no need to say anything about worms, which always find their way into pots where the bottom of the pot is not secured against their entrance. This can easily be done by placing a bed of coal-ashes 2 inches thick beneath them, and the ash-bed is even better than pavement or boards, as it retains the moisture and gives it off in a hot day. This is the usual time for cleansing the plants and staking all those which require support. No fire will be required till frost of some severity comes.

Potting bulbs for forcing.—For the most part the imported bulbs are sound and good. Roman Hyacinths are, perhaps, the

only exceptions. Some of these show traces of disease, and are smaller and dearer than usual. English-grown Narcissi—at least, those bulbs which have come—are superior to the Dutch-grown bulbs. Get the potting and boxing done as soon as possible, and cover the bulbs with Cocos-nut-fibre. Lillium Harrisii, which is now to hand, should be potted and plunged in fibre in cold-pit to make roots, when the plants can be moved to the house where a little forcing is done.

Window gardening.—Frost lies near. Get all tender plants lifted and placed under cover. In case of a sudden lowering of temperature, cover any plants wanted for the future with canvas or tiffany till they can be lifted. Scarborough Lilies will soon be in flower, and may have weak liquid-manure.

Outdoor garden.—The Rudbeckias are bright autumn flowers. They have long, stout stems, and last well in a cut state. The two best are *R. speciosa* and *R. purpurea*, and these are distinct and good, and everybody should plant them. They come in well with the Japanese Anemones and the early-flowering Starworts or Michaelmas Daisies, some of which everybody should grow. They are splendid furnishing material for new gardens to fill in the shrubbery till things grow and the place gets furnished. When once introduced a place will surely be found for them somewhere. They will form background plants in the borders, and they are very effective in masses of one colour near the margins of the lawn in retired spots, and certainly must be used in the wilderness, where they associate well with Tritomas, Polygoum cuspidatum, and other plants of similar habit, including the tall single Sunflower Miss Mellish, which flowers freely till cut off by frost. This is the best time to sow Grass seeds in new places. Prapara the ground well, roll it firm, and cast on plenty of seeds. Scratch them in with the rake, or cover with rich compost, and roll down firm. The seeds will soon germinate, and, if birds are troublesome, run strings of black cotton over the lawn a foot or so from the ground. When this is done the birds will not interfere with the seeds. Anyone thinking of planting Laurels should get the round-leaved variety. It is hardy and dwarf.

Fruit garden.—Hitherto the season has been most unfavourable for the ripening of fruit, especially what are termed soft fruits, such as Plums, etc. The latter are cracking a good deal, and this, of course, means decay and loss of crop. It requires a very even temperament to keep pegging away and at the same time maintain a smiling countenance under such circumstances, but this is the only sensible course to take. We must, of course, take note of things with a view to rectify any errors of culture or management, and as the planting season is close at hand we want to decide to the best of our judgment the right kinds to plant. From all my sources of information comes a good opinion of Newton Wonder Apple, and there will probably be a run upon this kind. Lane's Prince Albert has an established reputation. Bismarck has very little colour this season in our district, and the fruits, as might have been expected, are hardly so fine. Last November a farmer who is turning his attention to fruit growing in the I-on district sent me a couple of dozen fruits of Bismarck that were, I think, the finest I have ever seen. His Cox's Orange Pippins also were good, showing that now the Fens are well drained there is an opening for the fruit grower. All he has to do is to dig deeply and fetch up a little of the boulder clay to mix with his lighter stuff. Doyenné du Comice Pear still maintains its reputation as one of the best early winter Pears, and the market grower may continue to plant Pitmaston Duchess, as its size will sell it, and it is a fair cropper when the trees have gained size and age, though it may require a little root pruning to bring it into bearing.

Vegetable garden.—There is plenty of Cauliflowers this season; in fact, they are too big, but the difficulty is to keep the Autumn Giant of a reasonable size. One friend of mine who had a rich soil used to sow his seeds thinly in deep drills or trenches, and thin the plants out to 9 inches or 10 inches apart, and then earth the plants up. In this way he obtained

smaller and closer-grown hearts, and many more of them on the same land. The Walcheren, when true, is an excellent Cauliflower for late use. When sown in May and planted in different aspects, a long succession is obtained. During the long damp time we have had the weeds have been a terrible trial, but they must be kept down or our self-respect will suffer, as no one can be happy when overwhelmed with weeds. The Potato disease has given much trouble, and there will be considerable loss of crop. Spraying, when done in time, has been useful. Even a dressing of newly-slaked lime, when applied before the disease has had a chance to spread, has been useful. The outside Tomato crop this season cannot be a success. We have for some time been gathering all the fruits as fast as they show the least change of tint, and ripened them under glass. In this way all the best fruits will come out well coloured. The disease is spreading, and on heavy, damp soil the loss will be great; but, to make amends, the indoor crop has been good, though in cool-houses the crop is late. Plant out Cabbages and Lettuces, and fill spare frames with half grown Lettuces and Endive for winter. E. HODDAY.

THE COMING WEEK'S WORK.

Extracts from a Garden Diary.

September 29th.—Several frames have been filled with Violets for winter and early spring blooming. We find Melon and Cucumber frames suitable, levelling the soil down and adding a little old leaf-mould and some sharp sand, and after planting scattering a mixture of charcoal-dust and wood-ashes among the plants, and firming the soil about them. A light shower will do good, but heavy rains will be kept out. Put in a lot of cuttings of the double-flowered Arabis albidula. Sowed Mignonette.

September 30th.—Fruit gathering is receiving attention, but care is necessary in not gathering too early. All fallen Apples are gathered up daily. The maggot is still present in some of the fruits, and must be watched and destroyed. Grease-bands arrested the progress upwards of many insects last autumn, and these will be used a little earlier this season. The Brown Turkey Fig on a warm stable wall with a south aspect is ripening its fruit well. The growth is kept thin.

October 1st.—Strawberry plants have been cleared of runners and weeds. Some of the best runners of leading kinds have been planted 6 inches apart in nursery beds for spring planting. A bed of late Asters is usually grown, being sown thinly outside early in May. These are useful to fill vacancies in beds and borders, as they can be lifted with balls, and will watered in scarcely feel a check. Commenced putting in Rose cuttings in prepared bed in shady border.

October 2nd.—Late Raspberries are bearing freely, especially that robust variety Belle de Fontenoy. Summer bearing Raspberries have been thoroughly cleared of all wood not required. Canes suitable for planting, and which may be required, have been planted in many beds, being well watered in and mulched. Late Potatoes are now being lifted. We have not seen much disease, but there is plenty of diseased tubers in the neighbourhood.

October 3rd.—Carnations in borders are being planted. Duplicates of each kind will be potted and kept in frames till spring. Potted the last of the Freesias and Roman Hyacinths. The latter have been plunged in Cocoa-fibre, but Freesias are better uncovered in cold-frame for the present. All the tender plants of any value have been placed under glass, and, as usual at this season, we have scarcely room enough to hold all.

October 4th.—Put in cuttings of Ivies, chiefly small-leaved sorts and the broad-leaved variegated variety of Madeirensis. The latter is often grafted on the Irish Ivy during the winter or early in spring under glass. Gathered a surplus of Scarlet Runners, and placed in earthen jars with layers of salt for winter use. Frost will soon spoil the Beans outside. We are still gathering a few late pods of Ne Plus Ultra Pea, second crop from seeds sown in June. Sowed Mustard and Cress in shallow boxes in warm-house. Mushroom beds are still being gathered from open air beds.

LAW AND CUSTOM.

Land subject to quit rent.—I have a house and garden, for which I pay £1 per year. I rent. The land was taken from waste land 70 years ago by my grandfather, and my father built the house on it. Can I sell it?—P. A.

[Yes, you may sell this land. You will have no title deeds, except the wills of your father and grandfather—if they made wills. In the absence of any will or similar document, a purchaser may take some objection to the title, but the solicitor who acts for you will get over the difficulty by obtaining a declaration from someone who has known the property and its ownership for a considerable period. The land can only be sold subject to the quit rent; that is to say, the purchaser must continue to pay it.—K. C. T.]

A neighbour's dog.—I am employed as gardener, with cottage found. A lady lives next door, and has the use of my yard. She keeps a dog, and allows it to run all over my garden, and, before I can let my children go out in the morning, I have to clear away the dirt made by the dog during the night. I have asked the lady to charge me by keeping her dog on her own premises, but she declines. What am I to do?—J. K.

[Probably the premises where this lady resides belong to your employer, and if so you had better complain to him and ask him to put the matter right. If he refuses, your better plan would be to give notice to leave, as if you take legal proceedings you may not improbably receive notice to determine your service. If the house where this lady resides does not belong to your employer, you may probably sue her for the trespass of her dog, but before advising definitely I should require to know under what circumstances the lady has the use of your yard, and how your garden is divided from or fenced from the yard.—K. C. T.]

Dog chasing trespassing fowls.—I live by the side of a highway, and have wired off a corner of my premises, and keep some twenty to six there. After feeding them in the afternoon I usually turn them out upon the road so that they may get fresh grit. On the other side of the road is a Grass field occupied by a neighbouring farmer, and my fowls naturally go into it. The farmer is in the habit of sending his dog after the fowls. Is he justified in so doing? If any of the fowls are killed or injured, can I recover damages?—P. URBAN.

[Yes; the farmer is perfectly justified in sending his dog to drive your poultry out of the field. You may think it perfectly natural that your poultry should enter the field, but it is equally natural that the farmer should resent their trespass. He has no right to injure them either by himself or by his dog, and if the dog worries one of the fowls you may recover damages from the farmer. But this does not mean that he may not drive the fowls out. He may in any case sue you for their trespass, and as you know their propensity to trespass, it is your duty to keep them at home. You have no right to turn them upon the highway.—K. C. T.]

Nuisance from bee-keeping.—My garden adjoins that of a neighbour who keeps bees for profit. The gardener is afraid of the bees, and will not work near them, nor yet cut the hedge dividing the gardens, and so we are over-run with weeds. Is there any remedy?—IGNORANCE.

[The case is somewhat analogous to that of the nuisance caused by cock-crowing. It is alike lawful to keep bees and to keep poultry, but they must be kept so as not to be a nuisance to neighbours. If the bees are of a particularly pugnacious disposition, I think you might obtain an injunction to prevent your neighbour from keeping them; but it is altogether a question of degree, and while one person may be afraid of the bees and find them a nuisance, another person may have no fear of them. When working in the immediate vicinity of the bees your gardener might protect himself by wearing a veil and gloves, if he is of a very nervous disposition.—K. C. T.]

Title to land.—Some 60 years ago my father took half an acre of moorland for the purpose of making a garden and building a house in it. He was to pay £1 a year for the land, and he built the house, cultivated the land, and walled it in. For about 40 years the landlord came each year and collected the yearly payment, but afterwards ceased, and nothing has since been paid nor even requested. Some tell me that if a man occupies land for over 12 years without paying any rent for it, the land becomes his own property; others say that he must occupy it for 20 years without paying rent before it becomes his own. Will you please tell me which is correct? I may say there never was any written agreement or lease.—L. H. K. B.

[At the first view I thought this to be a case of a quit-rent, and not of an ordinary tenancy, and that the landlord in question was merely the lord of the manor. Possibly this view was correct, but it is perfectly immaterial. Where

a quit-rent is payable, the lord of the manor or other person entitled to receive the quit-rent is entitled to it and to it only, and has no title to the land itself, and he cannot increase the amount of the quit-rent under any circumstances. A person who occupies land for 12 years, without paying rent or making any acknowledgment for the land, does not thereby become the legal owner of it, but it practically amounts to the same thing, as the land cannot be recovered from him in an action. (But this would not be the case if he held under a lease for an unexpired term of years). You cannot now be dispossessed of this land, neither can you be compelled to pay any rent—whether quit-rent or otherwise—but you must be careful to pay nothing to anyone in respect of the land, nor to sign any document or agreement concerning it.—K. C. T.]

BIRDS.

Redpoll losing its bright plumage (N. B.).—Yes, these birds lose their distinctive markings on their first moult after being caged. In a garden aviary, however, they retain their beauty of plumage, and the males acquire the carmine red upon the sides of the neck and breast, as in a state of freedom. Do not give your bird much Hemp-seed (only a few grains now and then), as this in quantity tends to darken the plumage, besides causing over-fatness, to which caged Redpolls are very subject. The staple diet should be Canary-seed, with a change occasionally in the shape of a little summer Rape, Linseed, Maw, or Lettuce-seed. Give also the flowering buds of Groundsel and the ripe stalks of Plantain-seed.—S. S. G.

The Linnet (C. L.).—This bird is a very sweet songster, and a great favourite as a cage-bird. It should be fed upon Canary-seed and Summer Rape, with occasionally a little Lettuce-seed, Maw-seed, and a few grains of Hemp, with a fair supply of green food, as Groundsel, Chickweed, and Plantain. In a cage it is liable to become over fat, and the exercise afforded by the range of an aviary is more favourable to its general health; it, however, sings better in a cage. It is one of our indigenous songsters, and is generally spread throughout our island, frequenting during the summer furze-covered commons, sheep-walks, wild lands bordering on woods, thickets, and rough hedgerows. There are usually two broods during the season, the nest being composed of Moss and the stalks of Grass, interwoven with wool, and lined with hair and feathers, and generally placed in a clump of furze. The eggs are of a bluish-white, speckled with purplish-red. Young Linnets are easily reared by hand on bread scalded in milk, and Summer Rape boiled or scalded to remove its acidity, soaked Canary-seed being substituted as they grow older. The male birds of this species breed very freely with hen Canaries in confinement. The Linnet differs much in plumage at different ages, the male of three years old being distinguished by having the forehead blood-red and the rest of the head roddish ash-colour, with a spot of black on the top; the cheeks and sides of the neck and the circle round the eyes have a pink tint; the feathers of the back are chestnut brown with paler edges, while the upper tail coverts are black, edged with reddish-white. The throat is pale yellow, with some dashes of reddish-grey; sides of the breast are blood-red, feathers being edged with yellowish-white. The quill and tail feathers are black, margined with white. The grey Linnet, or male of one year old, wants the red on the head, the top of which is more dashed with black than in older birds, the breast having but a pale wash of carmine. After the second moult, however, blood-red specks may be seen making their appearance, if the feathers of the head be turned aside and examined, while the red of the breast is only hidden by the wide yellowish-white borders of the feathers. These tints soon disappear in a state of captivity, and birds captured in their finest plumage lose their bright colours at the first moulting, and remain afterwards grey. On the approach of winter, these birds assemble in flocks, and traverse the moors cultivated parts of the country, or descend to the sea-coast, till they separate in pairs on the return of spring to revisit their old breeding places.—S. S. G.

POULTRY.

GOOD WINTER LAYERS.

STRONG, heavy-feathered birds of a vigorous constitution are, no doubt, able to stand sudden changes of weather, and thrive in cold districts better than thin-feathered breeds, and for production of eggs in winter and strength of constitution there is probably no breed that can surpass the Brahma. The hens of this breed lay a larger number of eggs than do Cochins during the winter, although the latter is considered one of the best breeds for all-the-year-round laying. Brahmas are also good foragers where they have their liberty, and, consequently, inexpensive to keep. The chickens are hardy and easily reared, and the pullets begin to lay at an early age. The eggs of this breed are large and of a brownish tint. Cochins, besides being excellent winter layers, are the best of all breeds for keeping in a limited space, having no inclination to wander. The pullets begin to lay at an early age, regardless of the season or state of the weather, and continue to produce eggs through the cold, dark days of winter. The hens are most valuable as sitters early in the season, becoming broody when other breeds are beginning to lay. The eggs are of a pale chocolate colour and of excellent flavour. A very fine cross for the production of winter eggs is the Minorca-Brahma, and very few breeds stand confinement better and thrive so well in a small space. They are very hardy, stand the coldest weather well, often laying when snow is on the ground. The Black Minorca will also lay well in the winter if kept in a sheltered situation, and has few superiors as an egg producer, while the size of the egg exceeds that of almost any other breed. It bears confinement well, although with a good range it is a good forager (finding a large proportion of its own food), so that not only is it largely kept by the town poultry-keeper as the breed that is suited for small space, but it is found equally suitable for the poultry farmer, especially where egg production is the chief source of profit. The large number of eggs produced by the Black Minorca is in great measure owing to its being a non-sitting breed.

As to winter management, the same conditions we choose for ourselves—air, light, warmth, and dryness—are those best adapted for poultry, and to insure these the yard should be well drained and gravelled, so that there may be no stagnant water. The poultry-house should, if possible, have a southern aspect, and the floor be formed of chalk and earth, well beaten to form a compact, solid mass and bear frequent sweeping, being kept well sprinkled with dry ashes. As fowls cannot obtain worms or insects in the winter, it materially assists in the production of eggs if they are supplied with small quantities of animal food, minced fine. It is also important that laying hens should have access to substances containing lime, such as oyster shells and old mortar, otherwise there is a liability of their laying shell-less eggs. Grass is of the greatest value to fowls, and, where they have not the advantage of a Grass run, some fresh vegetables should be given them daily. A Cabbage suspended by its stalk affords them good, healthy occupation; otherwise, the leaves may be cut into small pieces and scattered like grain. Turnips, Carrots, Potatoes, etc., boiled and mixed with the soft food, conduces to good health. The best way of feeding is to give soft food warm first thing in the morning, kitchen scraps at midday, and good, sound grain at night before going to roost. Birds fed upon a judicious mixture of soft food first thing in the morning continue in better health and lay a far greater number of eggs than do those fed entirely upon grain.

S. S. G.

Photographs of Gardens, Plants, or Trees.—We offer each week a copy of the latest edition of the "English Flower Garden" for the best photograph of a garden or any of its contents, indoors or outdoors, sent to us in any one week. Second prize, Half a Guinea.

The Prize Winners this week are: 1, Mr. R. G. Pringle, Charlton Gardens, Colingbury, Gt. Br. Tree-Pony Mme. Stuart, Low, 2, Miss Harrison, The Old House, Whitehill, Sunderland-on-Wear, for Lupins and Irises, 11

CORRESPONDENCE.

Questions.—Queries and answers are inserted in *GARDENING* free of charge if correspondents follow these rules: All communications should be clearly and concisely written on one side of the paper only, and addressed to the EDITOR OF *GARDENING*, 17, FURNAL-STREET, HOLBORN, LONDON, E.C. Letters on business should be sent to the PUBLISHER. The name and address of the sender are required in addition to any designation he may desire to be used in the paper. When more than one query is sent, each should be on a separate piece of paper, and not more than three queries should be sent at a time. Correspondents should bear in mind that, as *GARDENING* has to be sent to press some time in advance of date, queries cannot always be replied to in the issue immediately following the receipt of their communication. We do not reply to queries by post.

Naming fruit.—Readers who desire our help in naming fruit should bear in mind that several specimens in different stages of colour and size of the same kind greatly assist in its determination. We have received from several correspondents single specimens of fruits for naming, these in many cases being unripe and otherwise poor. The difference between varieties of fruits, as, in many cases, so trifling that it is necessary that three specimens of each kind should be sent. We can undertake to name only four varieties at a time, and these only when the above directions are observed.

PLANTS AND FLOWERS.

Keeping Begonias (M. C. L.).—Lift your Begonias when the first frost has hurt them, lay them in a frame, and when the growths have all fallen off, clean the bulbs over and lay them into sand in a box, plaing them under the greenhouse stage so that no drip can fall on them. A cellar, where no frost can penetrate, will answer as well.

Sowing Grass-seed (John Part).—October is too late to sow Grass-seed. If you cannot sow during the present month, wait till March or April. If sown in March there is no reason why you should not have a good lawn during the following summer. Sow thickly, make the seed-bed firm, and run black cotton over the seeds to keep off birds.

Tropeolum speciosum (S. Border).—Leave the seeds on the plant until they are quite ripe, when at once sow in a pan or box in light loam, leaf-mould, and sand. Place in a pit or frame and keep the soil moist, but not too wet, until the seedlings appear in the spring. Careful division of the roots is, however, the best way to increase this.

Fungus on lawn (A Constant Reader).—Your only chance is to prevent the casting of spores, and by picking them early you may in time reduce them. At the same time, you have the worst evil to contend with underground in the mycelium or spawn running about. It is possible some very strong brine poured into the patches may kill the spawm, or some weed-killer may do likewise. The best time to apply either of these is when the peat is most active.

Roses for pillars (Stafford-hire).—Some good Roses for posts and chains may include the cluster kind, as *Aimée Vibert*, *Dundee Rambler*, *Alice Grey*, *Reine Olga de Wurtemberg*, *Frances Bloxam*, *Pélicie-Perpetue*, and the fine single *Provence Rose*, *R. setigera*. The posts may be 5 feet to 7 feet asunder. There is no objection to planting Clematis in conjunction with the Rose; indeed, it is frequently done. All the Roses named are good. *Cheshunt Hybrid* is one of the earliest to flower of red climbers.

Carnations from seeds (J. W. L.).—Sow the seed in March or April in pots or pans of fine soil, and plunge in a brisk bottom heat. The soil must be kept dry damp, so that no watering is necessary until the seedlings appear. As soon as fit to handle, prick off into other boxes about 3 inches apart, and allow to remain in warm frames until established, gradually inouling the young plants to the air. When well established the seedlings may be staked in a cold-frame, and, by the first week in May, the lights may be removed and the young plants set out where they are to flower.

Snapdragons in winter (R. J. S.).—These plants will be quite safe in the frames, giving air on all favourable occasions. If in boxes use light soil and plant firmly. Very little water will be needed from November to end of February, but the soil must not be allowed to get quite dry. If the plants are now in boxes, and with room to develop, leave them alone, but if at all thick and likely to spoil, transplant at once into other boxes. In cold weather the plants will be safest if nearly or quite dry. In this respect the treatment will do for Geraniums, but these will not endure frost.

Carnations falling (B. D.).—We could find no grub of any kind, but from the shoot sent should say that wireworm is the cause of failure. If wireworms show themselves in a bed of Carnations, the best way is to place slices of Carrots on the ends of pointed sticks. Bury the slices 2 inches or 3 inches in the ground, and examine them daily and destroy them. The wireworm will be found on the Carrot slices. A good way is to dress the ground where the Carnations have been with gas-lime, working this into the ground and letting the soil lie fallow for a year, frequently stirring it, so as to well incorporate the lime.

Good Carnations (Stafford-hire).—You cannot do wrong in planting any of the fragrant salt kinds, such as *George Macquay*, white, *Countess of Paris*, *Carroll Duran*, *Sadek*, *Waterwitch*, *Braw Lass*, *Miss A. Campbell*, *Hayes' Scarlet*, *Boadicea*, all good. A few old sorts for free mauling should include *Old Glove*, *Gloire de Nancy*, *Ruby Castle*, *Duchess of Fife* (plant in a little shade), and *Alice Ayres*. Another year if you want flowering plants where the Snapdragons are now, it is possible the Tuberous Begonia may suffice. If you are not particular as to flower, and there is room, and the Roses fall enough, why not plant young *Lavender*? This would be quite in keeping with the old flagged terrace.

Climbing Rose (Lande, W.).—The only likely Rose to succeed is such as *Aimée Vibert* or *Mme. Lambert*. The *Reine Olga* may also do well and the yellow *Tree-Lupin* is worth a trial. If you tried a mixture of these, you could not do worse than to try *Tropeolum speciosum* all along the

wall to climb over the other things. It sometimes succeeds quite well in this aspect. If you wanted a solitary plant merely for cover, the one plant we should at once name is *Eunonymus radicans variegata*. It is non-flowering, so to speak, but is self adherent in such cases. You may certainly write us again.

Twelve good Phloxes (Amateur).—The following should suit you: Whites, Myrtle and Mrs. F. H. Jenkins; rods, Etna and Cocquilleot; salmon, Lother and A. F. Barron; bluish-pink, Mme. Malisset; orange-scarlet, Embrassement; black, Lerviche; rose-lilac, and slate, Balzac; soil lilac, Cendrillon; crimson, Cocinea; white, crimson eye, Countess of Aberdeen; white, purple eye, Edith. While the above are a good set, it is quite possible you would be best supplied by placing your order with any of the hardy plant dealers, stating your wants and leaving the selection to them.

Fern unhealthy (E. J. Fleming, Stanhope House, Stribton).—The Fern, *Cyatium anomalophyllum*, which you sent us appears to be suffering from bad action of the roots, but it is difficult to pronounce with certainty, as the same results are often due to the presence of thrips, and the frod received is too shrivelled to say for certain, but it appears to be free from insects, therefore see that the soil in which your Ferns grow is not kept in a constant state of moisture, which has for consequences the rotting of the spongyules of the roots. Exposure to strong light would also cause it, but this can scarcely be the case this season, therefore see to the state of the roots. Gladioli bulbs should not be planted in the border in the autumn. Plant them about April-May, and take them up in autumn, and if on a cold or stiff clay ground plant only in May-June, but always take them up in autumn.

Roses for beds (Staffordshire).—For the new Roses the following kinds would be suitable: Comtesse de Saxe, rich light salmon, shaded copper, fine foliage; Bougere, rich salmon and of good substance; Ernest Metz, rose-pink; Jean Ducher, yellow, shaded pink, a grand Rose; Jean Perret, rich apricot; Lucile, fine rose-carmine and copper; Mme. de Watteville, white, salmon, and rose, wants thinning of the buds; Marquise, de Viviers, rose-pink; Marquise Litta, rose-carmine; Mme. Jules Grolez, salicy-pink; Mme. Abel Chateaux, rose-carmine, shaded vermillion, rose, and salmon; Grace Darling, pink and peach, extra; Lady Battersea, cherry crimson and orange; Liberty, brilliant velvet crimson; Lady Mary Fitzwilliam, flesh, extra fine; Gris an Topitz, scarlet-crimson, grand; Camoens, satin-rose; Shandon, deep carmine, reddish centre, sweet; The Meteor, velvety crimson; Viscountess Folkestone, creamy-pink and salmon, large, fragrant, and free. The H.T.'s are marked with an asterisk. The others are Teas, and all of merit. We would suggest planting six or more in a block for effect, and the plants should be about 2 feet apart.

TREES AND SHRUBS.

Climber for arch (Eria).—Yes, the Honeysuckle will do quite well, and if you have room you may plant the Crimson Rambler Rose to bear it company. The two plants are excellent in combination in this way.

Planting Azaleas (Anon).—We are assuming the soil will be deepened and improved to suit the Azalea. Groups of Lilies would be charming, and among late-flowering shrubs there are several Iroonis, including G. Andreana and the yellow Spanish. The latter might be kept down by pruning. Hardy Fuchsias would be nice. Hydrangeas would do, both H. Hortensia and paniculata grandiflora, also Althaea frutex (Hibiscus) in variety, but do not overwater.

Blight and Birch-trees (Birch Tree).—Judging from your description, the kind you refer to is probably *Betula alba laciniata pendula*. The small leaves you send give us no opportunity of expressing an opinion other than that they appear to be tolerably good health. If aphides are really present, this may be readily got rid of by syringing with some cheap wash, petroleum and soft-soap, for example, or these in conjunction with Quassia solution, the intense bitterness of the latter remaining effective a long time after the application.

Berry-bearing Ivy (M. B.).—This is usually known as 'tree-ivy' and in certain parts gets beyond the limits of training and having no support forms a hard, woody growth that it is hardly possible to root. If the berried shoots are in a position to admit of it, your only chance is to layer the shoots either into boxes or pans of soil. If detached from the parent plant, the pieces so detached would only linger and die. By watching some of the younger shoots, you may perchance get some to root in the way mentioned, but even then it is slow work.

Laurels and Hollies (Ecogreen).—If the laurels are large and have been many years in one position, the removal may go hard with them. Indeed, it would be best to prepare these and the Hollies by digging round them at once and separating the large roots at 2 feet from the stem. This will cause fresh fibrous roots to form, and it is upon these that the freshly-planted tree depends for its fresh start. You may also prune the Laurels somewhat, but not the Hollies. The former may then in early spring be replanted, and the Hollies in early June. Thus treated, any fairly good light loamy soil, to which some decayed manure may be added for the Hollies, will grow them quite well.

FRUIT.

Mildewed Vines (Peggy).—You will have noticed, no doubt, that we have replied to others in regard to the Vins midew, which seems to be very prevalent this year, arising from the heavy rains chilling the borders, cold air, and absence of sunheat. Yours is a very bad case. Get 1 lb. of sulphate of copper (blue-stone), and dissolve it in a wooden tub in boiling water. Also dissolve in a pint 1 lb. of fresh lime and add the liquid to the other, also 1 lb. of soft-soap. Then add 9 gallons of water, and when clear well spray or syringe the whole of the Vines with it. Cut all the Grapes first, as this is poisonous.

Canker on Apricot-tree (C. S.).—The Moor park, the best of all Apricots, unfortunately, is more prone to canker than are most other varieties. You may be able to check the spread of the disease if you will lightly scrape over the cankered portion, then will make up a compound of clay and paraffin, and rub on the wound with it. We seem not to have found a stock on which this Apricot will do well over many years. Seedling plants are sus-

ceptible to canker, but then seedlings may prove to be of very poor quality. Apricots like a very firm soil, and there should be forked in with yours (probably sandy) some clay, wood-ashes, and old lime refuse. Well tread the ground over the roots.

Pruning outdoor Vine (Mrs. P.).—You should have cut your Vine hard back soon after it was planted to cause it to send up a strong shoot or rod the following season. You do not say when you planted it, but we assume that it was just winter. If so, as you did not do so then, our proper course will be to cut until all the leaves have fallen, and then to cut back any shoots made this season to fully one-half their length, nailing in the portions left. Those portions should break strongly next year. Whether the shoots then will carry bunches or not will depend on their strength. You will have to prune every winter in about the same way, leaving on the Vine only stout, hard, well-ripened wood. If you do not prune, your Vine will soon become a mass of shoots, and worthless.

Blighted Vine-leaves (E. A. T.).—The Vine-leaves sent are foul with the excrement of aphids, and your best course now that the fruit is gathered is to shut the house up as close as possible, then to smoulder in it so as to fill it with strong smoke some Tobacco or Tobacco-paper. When the house has been filled, keep it close for an hour. Next morning give the Vine a good syringing with hot water. Give a second smoking three evenings later, and treat as advised. When the leaves fall sweep all up and burn them. Prune the Vine as soon afterwards as possible, and burn the canes. Then give the Vines and the entire house when quite empty a syringing with solution of caustic soda 1 lb. and of potash 1 lb., and 10 gallons of water, used as hot as possible. That should destroy all insects.

A good outdoor Vine (C. J.).—Generally, the most reliable outdoor Vine for producing in this country fairly good fine Grapes is the White Sweetwater, or perhaps more properly named Royal Muscadine. It is also the White Chasselas of the French. This Grape will usually set well, and it pays to have some of the best bunches thinned a little in the early summer. Wasps and flies are fond of the sweet berries, and, therefore, as they approach ripening, it is well to enclose the best bunches in muslin bags to keep off these pests. There is a really first-rate outdoor Grape known as Reine Olga, the berries of a reddish hue, which usually does remarkably well outdoors on a warm wall. It is not yet largely grown. Perhaps it may be well to obtain and plant both varieties, and see in a few years which you like best.

Peaches under glass (M.).—It is very difficult to determine the actual cause of your Peach-leaves turning yellow, except on full examination of the condition of the border in which the roots are. No doubt the cause is to be looked for there. You should open a hole on the border and judge as to the condition of the soil. If you find it stiff, clammy, and poor, no wonder the leaves turn yellow. In such case, the best thing to do is to remove carefully with a fork all the surface soil, then get up all the roots, preserving them, and covering up with straw. Then excavate the bottom soil about 10 inches in depth, remove it, and replace with good soil from the vegetable quarters, and one-third of turfy loam; also add wood-ashes and some old lime refuse. Relay the roots about 6 inches below the surface, and when the soil is filled in add to the top a mulching of long stable-manure. If inside the house give also a moderate watering, and others at intervals through the winter. Perform what is advised so soon as the fruit has been gathered.

SHORT REPLIES.

T. G. White.—You ought to apply to an analytical chemist. —**Flurist.**—Do not cut the foliage of your hardy plants until it has properly ripened off. You had better leave the Madonna Lilies as they are, and top-dress them with some light, friable soil. The best time to replant is immediately after flowering. —**Rosic.**—We doubt very much if Ivy-leaved Pelargonium, even if protected, will stand the winter; but you can only try. If you have any plants, stand in a frost-proof house during the winter, and pot on in the early spring. Do not cut them down. —**J. Izzard.**—Leave the Rose shoot as it is, only cutting off in the spring the unripened and soft wood. It will break out and flower freely next spring. Yes, you can grow it along with the Vine. —**W. Moorling.**—Very difficult to advise without further particulars. Very probably you are keeping too close to the wall. Admit all the air you can and they will soon recover. —**G. M. S.**—We have given selections of Roses in previous issues, which consult. —**Enquirer.**—In such a soil as yours you cannot do better than mulch well with cow-manure when the plants have died down. The goodness of the manure will then be washed down to the roots by the winter rains. —**G. M. Mordant.**—Sorry to say we cannot help you. —**F. K. Peto.**—You certainly cannot use a weed-killer in any place to which animals have access. Weeding and hoeing are the only remedies in such a case. —**W. C. N.**—Start at six in the morning, with three quarters of an hour for breakfast at eight o'clock, an hour for dinner at one, leaving off at six, no time for tea. These are the hours from which you should start. Of course, if it comes over time, you must pay him or allow day occasionally to visit other gardens in lieu of money. —**Journepinal.**—Your best plan will be to try and get employment in some of the large market nurseries round London. —**C. J. Page.**—We dealt with 'Strawberry growing in tubs' in Vol. XXI., the discussion lasting several weeks. The numbers can still be had by applying to the publisher. —**Bilberry.**—Not a gardening query. —**Sky.**—Let the Vine start naturally. In such a house there is sufficient moisture without any syringing. —**A. M. L.**—If you have well manured the ground for Michaelmas Daisies, there is no need for any feeding. Liquid-manure would be the best for them. —**K. E. S.**—You cannot do better than try *Pasiflora corulea* and its white variety *Constance Elliott*. —**Leilid.**—I have a description and illustration of the Persimmon in the issue of Feb. 14, 1901, to which you can refer for a full description, price list. You do not say how old your Vine is. You can keep it to the length of stem you say, but in this way you sacrifice the crop of fruit, as the longer the stem the more bunches. —**M. J.**—You cannot do better than try Hollies in variety. —**Yes, Box, Thuja, Juniper, Evergreen Oak, Pleura, Magnolia, beautiful in flower, and Berberis in variety.** —**W. P.**

I. We do not understand your query re Tomatoes. As it depends on the heat you can command, and the time when you start the trees. —**Worcestershire.**—Kindly give us some idea what you want, and then we shall be glad to help you. —**Greenhouse Builder.**—Your best plan will be to make a border and to plant the Tomatoes in this. —**Red Gemble.**—The amount of piping you have is quite sufficient to keep out frost—that is, if the boiler is powerful enough, which we fear it is not. —**Isfort.**—An ordinary small oil stove of good quality should suffice to keep your greenhouse at the required temperature, or there are stoves, such as the 'Challenge,' made for this purpose. Rippington's Albion Lamp Co. make a specialty of lamps, and propagating-cases combined. —**Chalk Subsoil.**—You cannot do better than get old peeing stones, which answer the purpose well. —**H. C.**—Yes, the Myrtle ought to do against a wall if you cover up in the winter. —**B. Phillips.**—Yes. —**North Country.**—Not at all unusual. —**Polo.**—See note in this week's issue re 'Holly-hocks,' p. 337. —**C. D. Massey.**—Send a specimen, and then we can help you. —**F. L. C.**—You can do nothing to rid the Vine of the mildew, the present season having been all against the growth of outdoor Grapes. —**J.**—Your best plan will be to build the rock earlier during the autumn and winter, and then put it early in the spring. The course is as soon as finished, you can, if you wish, fill any of the spaces with any bulbs you wish to grow. —**L. A. C.**—You cannot do better than plant *Glaire de Dijon*. —**Rosic.**—1, Certainly. 2, Plant when the ground is neither too wet nor too dry. 3, Hardy plants may be set out either in the spring or autumn immediately after flowering is over. 4, No need to cover with ashes. —**M. C. L.**—Certainly, you can plant *Dafodils* among the Tea Roses. The mulching will be an advantage rather than otherwise. —**Mrs. Hudson.**—See article in coming week's issue re 'Violets.' —**Lavender.**—We prefer not to say. —**F. G. N. Somerset.**—Only natural that such should happen, as the flowers continue opening in succession. The soil has nothing to do with it. —**Anon.**—Give us a good collection of hardy and bulbous plants, and you will never be without bloom all this year.

NAMES OF PLANTS AND FRUITS.

* Any communications respecting plants or fruits sent to name should always accompany the parcel, which should be addressed to the Editor of GARDENING ILLUSTRATED, 17, FURNIVAL-STREET, HOLBORN, LONDON, E.C. A number should also be firmly affixed to each specimen of flowers or fruit sent for naming. No more than four kinds of fruits or flowers for naming should be sent at one time.

Names of plants.—**Lady Jane Grey.**—1, *Tridax* sp. probably, specimen insufficient; 2, *Lyceasteria leucocoma*. —**John Hutchinson.**—We cannot undertake to name Roses. —**L. D.**—1, *Abies sp.*; 2, *Variegated Hollock*; 3, *Spiraea Douglasii*; 4, *Galaxia officinalis*; 5, *Red Valerian* (*Centranthus ruber*); 6, Specimen insufficient. —**Flora.**—1, *Ipomoea Scapularis* (*Saponaria officinalis* fl. pl.); 2, *The Gilly-flower* (*Echium anthemum*). The only one you can do with is *Scapanus* if you grow in pots, but we doubt if it will succeed; all are like the one you send. —**C. C. M.**—Flower too dried up. —**P. J. Williams.**—1, *Arum crinitum*; 2, *Tecoma radicans*. —**Sarina.**—1, *Hibiscus syriacus* var.; 2, *Begonia* specimen too poor; 3, *Sedum carneum*; 4, Please send better specimen. —**Val.**—1, *Bouvardia jasminiflora*; 2, *Stephanotis floribunda*. —**R. Greening.**—1, *Pyrethrum uliginosum*; 2, *The Japan Knotweed* (*Polygonum cuspidatum*). —**H. P. J.**—Apparently the white, rose, and purple forms of *Malope grandiflora*, but such withered specimens afford us no opportunity for accuracy, and debar you obtaining the information you seek. 1, *Ipomoea Stolon*; 2, *Venturum nigrum*; 3, *Aster hypopitellus*; 4, *Solidago multiradiata*; 5, *Azolla bennettiana*. Thanks for sending such good specimens. —**J. W.**—If you will send them in flower we may be able to help you. —**M. A. C. R.**—*Senecio Doris*. —**R. G. H. Hadon.**—Japan Knotweed (*Polygonum cuspidatum*). —**J. W. L.**—Yes, the bloom of an alpine Auricula. —**Arthur Birt.**—*Rhamnus Frangula*. —**Anon.**—1, *Tecoma fruticans*; 2, *Abelia rupestris*; 3, *Eunonymus japonicus*; 4, *Elaeagnus glabra*. —**Noz.**—1, *Wellingtonia grandis*; 2, *Sequoia sempervirens*; 3, *Abies alba* (?); 4, *Cupressus Lawsoniana*.

Names of fruits.—**Rev. A. H. Watson.**—1, *Pear Marie Louise*; 2 and 3, Specimens too poor; 4, *Man Codlin*. —**X. Y. Z.**—Apple *Cellini*. —**Z. O.**—Apples: 1, *Small Emperor Alexander*; 2, Not recognised; 3, *Cellini*; 4, *Lord Deeby*. It is almost impossible to name when, as in your case, only one specimen is sent. —**Holmald.**—*Plum Mitchellson's*. —**Cambridge Wells.**—Kindly read our rules as to naming fruit. —**F. T. P.**—It is early yet to name Apples generally, as the fruits are far from being in their true form. No. 1 is evidently *Tower of Glamis*, although the two fruits sent are greatly unlike. No. 2 is *Cellini Pippin*, No. 3 *Small's Admirable*, and No. 4 *Wheeler's Russet*. With the exception of quite early varieties, Apples or Pears cannot all be correctly named before October, or, at least, until fully grown.

Catalogues received.—**W. Smith and Son, Aberdeen.**—*Catalogue of Flower Roots, &c.* —**W. Samson and Co., Kilmarnock.**—*Bulb Catalogue.* —**Harrison and Sons, Leicester.**—*Spring-flowering Bulbs and Roots.* —**Ann Roozen and Son, Haarlem, Holland.**—*Dutch and Cape Bulbs.* —**Wm. Sydenham, Tamworth.**—*List of Bulbs.* —**Jas. Craven and Co., 4, Manners-street, Wellington, N.Z.**—*Seed Annual, 1902-3.* —**Pinehurst Nurseries, Pinehurst, N.C.**—*List of American Seeds.* —**East Angles Plant Co., Great Totham, Witham, Essex.**—*Flora and Beautiful Plants.* —**H. Cannell and Sons, Wexley, Kent.**—*List of Bulbs, Strawberries, and Small Fruits.* —**Edmondson Bros., Dame-street, Dublin.**—*Autumn Catalogue.* —**W. Bull and Sons, Chelsea, S.W.**—*List of Bulbs, &c.* —**Dickson's, Chester.**—*List of Bulbs, &c.* —**F. S. Ware, Ltd., Feltham.**—*Bulbs and Plants for Autumn Planting.* —**John K. King and Sons, Coggeshall.**—*Choice Flower Roots.* —**Pope and Son, Birmingham.**—*List of Dafodils.* —**Geo. Bunyard and Co., Maidstone.**—*List of Fruit-trees, Roses, &c.*

PLANTS AND FLOWERS.

INDOOR PLANTS.

EARLY POTTING OF BULBS.

UNDOUBTEDLY October is the best month for potting and boxing bulbs in general, except those that are needed for early forcing, and then a month earlier is advantageous. It is no uncommon thing to hear growers complain in spring of the unsatisfactory blooming of bulbs, and the Editor knows this from the many inquiries that reach him for advice. I believe the major part of the failures arises from bad treatment of the bulbs, and late planting is responsible for many of them. This is not difficult to understand if the cultivator will but give a little thought. How can bulbs be expected to be satisfactory if they have been exposed to the air for months? Were they in the soil they would commence rooting by the end of August, and would not have had any of the sap dried out of them. I have tried placing bulbs in September in boxes and pots without soil in a moist place in my fruit-room, and they began rooting at once. Nor do I think keeping them out of the ground so long retards them to the extent many imagine. I have noticed that when potted so late the bulbs begin to make leaves before they are well rooted, giving often poor, weak, deformed blooms. I am aware November is soon enough to plant in the open ground, but here they bloom later. It is important amateurs and beginners in their culture should understand this, especially now that most bulbous plants can be purchased so cheaply. Nor is it necessary to have a heated glasshouse to have them in bloom early in the year. I am convinced no place is so satisfactory to grow most of them (except the tall-growing Lilies) as pits and frames. Many a fine lot of bulbs, such as Narcissi, Tulips, etc., has been ruined by bringing them when insufficiently rooted into a dry, hot house and standing them on dry shelves. Far better allow them to remain in a moist pit, or place them on a bed away from drying heat. Such things as grow in moist situations and amongst the Grass cannot be happy on shelves. When the spikes are advancing, then they may be brought near the light, but there should be abundance of moisture both at root and top. Good early bloom may be had without fire-heat of any kind, and those who enjoy them in their rooms may bring them forward in pits and frames before bringing them into the drying heat of dwelling-rooms.

Last year I tried growing Narcissi, Tulips, Hyacinths, and other bulbs generally grown in pots, in garden frames, and pits. I have never seen them bloom better than when thus treated. Early in October these were potted or boxed, placing them under ashes on a cold border. When well rooted they were removed into a frame on an old, spent hot-bed, where Cucumbers had been grown in summer. When the nights were cold the lights were well covered. Early in January I filled a pit with fresh tree

leaves for sowing Carrots on. One light was set apart for bringing forward bulbs. When the bed had settled, this was filled with pots and boxes of bulbs, standing them close together; the slight warmth from the bed brought them on, and, being close to the glass, they were very sturdy. When the blooms were about to open, the plants were removed to a light house to bloom. Should leaves not be available, then anything that produces a slight heat, such as tan, or manure, provided it is not used in a fresh, rank state, may be used to stand them on. To be successful, obtain good bulbs, pot early, bring on slowly, and never allow them to get dry at the root.

J. CROOK.

GROWING LAPAGERIAS.

I HAVE a lean-to greenhouse, 17 feet long and 10 feet to the top. It faces east, with a slight turn to the north. I want to grow Lapagerias in it, so please will you answer in your valuable paper the following questions: 1. How many Lapagerias can I grow in said greenhouse, training them up against wall? 2. Would they do in the same heat in winter with Palms, Araucarias, etc. (mild and moist heat)? 3. How long would they flower? Advice as to watering and general culture thankfully received.—A. R.

[A couple of old-established plants of Lapageria would cover the space given, but they would, of course, take some years to attain these dimensions, hence we should advise putting young thrifty plants 2 feet apart along a prepared border, or, if you are inclined to wait a little longer, 3 feet may be allowed between each. The red and the white varieties might be planted alternately. Lapagerias are by no means all of equal merit, hence the best forms are usually in nurseries propagated by layers, which when well rooted are mostly put into pots 6 inches to 8 inches in diameter. After about twelve months in these pots they are thoroughly established, and it is plants such as these that give the greatest amount of satisfaction when planted out, as they soon take hold of the new soil, whereas those that have been in pots for years become more or less cramped, and are difficult to start out of that condition. Once established, Lapagerias will grow and flower well year after year with but little trouble, hence the planting should be thoroughly done, for if confined in pots they are never satisfactory for any length of time. As the Lapageria when growing needs a plentiful supply of water, drainage is very important. When making the border remove the soil to a depth of 2½ feet and the same in width. Then, provided the subsoil is sufficiently open to allow of water draining away, a foot or nearly so of broken crocks, brick-rubble, or anything in that way may be put in the bottom, and over that a layer of thinly-cut turves with the grassy side downwards. Then fill the border with a mixture of about four parts good fibrous peat to one part nodules of charcoal or soft bricks, broken to a size varying from Hazel Nuts to Walnuts, and one part of sand. When pressed down firmly the Lapagerias may be permanently planted in this mixture. Till the roots take hold of the new soil care must be taken not to overwater, while just as the young and succulent shoots appear above ground a sharp look-out must be kept for slugs, which

soon destroy them. 2. Lapagerias are essentially greenhouse plants—that is to say, the structure in which they are growing should not fall below 45 degs. in the winter. During the summer a liberal use of the syringe is beneficial. 3. Generally speaking, they will flower for about three months.]

NOTES AND REPLIES.

Slow combustion stoves.—Will any reader who has successfully used a slow combustion Tortoise stove for heating a small span-roof greenhouse, say, 20 feet by 10 feet, kindly give his experience?—J. F. C.

Vallisneria spiralis.—How should Vallisneria be treated? Mine has hardly grown an inch all the summer. It is in a tumbler on a window-ledge.—N. E.

[This is a floating fresh-water perennial, whose flowers live under water, except just at the time of impregnation. It ought to be grown in rich loam in a good sized pot, plunged deeply in a tub or cistern filled with water.]

A malformed Agapanthus bloom stem.—Last week I saw at St. Austell what appeared a very interesting example of fasciation in a plant of Agapanthus umbellatus. There was a flower stem of nearly 2 feet 6 inches in height, flat, except for corrugations, tapering from 2 inches in width at the bottom to 1½ inches at the base of the umbel. But the most curious thing was this: Quits among the leaves of the base was another umbel, the flower stalks appearing (without very precise observation) to rise from the ground quits as independently as those of a Primrose. The leaves and these flowers were completely mixed. It would seem that the one umbel had actually robbed the other of its stem, though the plant was so strongly grown as apparently to make this unnecessary.—C. R. S.

Raising Schizanthus from seed.—I should be very much obliged if you could give in an early issue of your valuable paper some directions concerning the culture of Schizanthus for spring flowering in the greenhouse. I saw some lovely specimens of Schizanthus pinnatus in a cool greenhouse last spring, each plant quite a soft cloud of delicately tinted blossoms. I got some seed about the end of July, and have a fair number of seedlings just potted. They seem to me, however, a little weedy, and slugs seem to attack them wherever they are put. The plants I saw in flower had strong stems, and were much branched, as if they had been stopped several times during their growth.—ANNON, Mansel.

[To obtain large specimens the Schizanthuses are sown in early autumn, potted off as soon as they can be handled, and kept during the winter close to the glass in a structure from which frost is just excluded. Seed sown in the spring will make useful flowering plants for the greenhouse in the summer. The one important item in their culture is to keep the plants as near to the glass as possible in the greenhouse, and allow a free circulation of air amongst them. The points of the shoots, too, should be pinched out while the plants are still small, and again later on if necessary. In this way good, sturdy plants are obtained, which will yield a fine display. Pots 6 inches in diameter are large enough for the spring sown plants to flower in. As the pots get full of roots an occasional watering with liquid-manure will be of great service.]

Treatment of Hydrangeas.—Will you kindly, in your next issue (as I have delayed writing too long), give me some information as to how I should treat my Hydrangeas? The article in issue September 6 does not give me the information I want. Last year I cut several plants

down, and not a single bloom this autumn; two other plants I did not cut down, and each has about six stems, very strong, about 2 feet high, and only one stem on each plant has any bloom, both very fine. Please advise best course to have blooms on all plants. I am afraid I must have done the wrong thing.—HIBERNIA.

[The answer in the issue for September 6th referred to the greenhouse *Hydrangea Hortensis*, but whether yours is that kind or the hardy *Hydrangea paniculata grandiflora* we are only left to conjecture. This latter produces long cane-like shoots, which should, before starting in the spring, be pruned back to the last two or three eyes—that is to say, cut back nearly to the old wood. The shoots then produced will each bear a large terminal pyramidal-shaped head of blossoms, which are of a creamy-white when first expanded, but after a time become flushed with red. To produce the largest heads of all, only about three shoots should be allowed to develop, but the effect is more pleasing when the plant carries six or eight clusters, though, of course, they are not so large. If the *Hydrangeas* are planted out in a bed fully exposed to the sun, pruned as above detailed, and watered when necessary (occasionally with manure-water), there is no reason why they should not flower well. If it is the ordinary *Hydrangea Hortensis* that you enquire about, we presume the plants are in pots, in which case you must bear in mind that they are liberal feeders. This *Hydrangea* is hardy in some parts of England, and where it is too tender for outdoor culture, the plants, which are often grown in large pots or tubs, should be stood out-of-doors in a sunny spot in order to ensure blossoms later on. A dose of weak liquid manure about every fortnight will be of great service. The less pruning a *Hydrangea* of this class receives the better, except it be the cutting out of any old and weak shoots which are apt to crowd up the centre of the plant. The fact that the name of the variety is not given, nor whether planted out or in pots, and if this last their size, handicaps us greatly in answering your question.]

Ginger-plant (*Zingiber officinale*).—Will you kindly inform me how this plant may be propagated? The plant is about six years old, and is now in bloom.—E. R.

[Under ordinary greenhouse treatment this flowers in the autumn, only plants that are well established blooming in a satisfactory manner. Those who have weakly-looking specimens should make an effort to get them strong. Nine-inch or 11-inch pots are very suitable sizes in which to grow the Ginger plant. Even in a large pot a strong plant will often produce but one good shoot in a year, but if well cared for it will reach to a height of 5 feet, with a noble spike of flowers on the top. Frequent root-disturbance is bad. Repotting once a year, and that early in the spring, is all they require. Being plants with numerous strong roots and rather large leaves, they require a strong holding soil to sustain them. A suitable compost is three parts turfy loam and one part peat, made pretty firm at the time of potting. Owing to the vigorous character of the growth, there is no plant more benefited by liquid stimulants than this, if given as soon as the flower-stems begin to rise. But it is not safe to apply the liquid before, or the result is likely to be nothing but leaves. In the case of amateurs, there is no doubt that this plant suffers sometimes during the summer months from the want of root-moisture, as a plant in active growth makes a good number of roots. Where it is not likely to be well attended to in this matter, it is better to stand it on the floor of the house, where the roots will be kept cooler, but it must have plenty of light and air. It is a good plan not to encourage the plant to form too many crowns; one strong flower-spike in a 9-inch pot is as many as it can support. For that reason some of the weakest crowns should be cut off when the plants are potted in the spring. They may be grown on to make flowering plants for the next year. It can be easily increased by division in the spring.]

Ivy-leaved Pelargoniums.—The all-round qualities of the Ivy-leaved Pelargoniums account for their popularity. In the wet weeks of the past summer, when other bedding plants have made wood at the expense of bloom, the Ivy-leaved Pelargoniums have come out best and flowered freely. Their long, trailing habit fits them peculiarly for window

boxes, flower-stands, and the like. One or two old plants held in reserve will supply one with many cuttings in March.—LEAHURST.

ROSES.

ROSES FOR SMALL GREENHOUSE.

I beg to take exception to the list of Roses supplied to "Alec" (p. 322) for his small greenhouse, and especially to the six first named kinds on the list. The selection is one not likely to impress a novice, as "Alec" says he is, as to the suitability of Roses for pot culture generally. I will take the first six as they appear. 1, Mrs. John Laing, 2, Ulrich Brunner. One of these twain is not wanted in a select half-dozen, with much the same character, and a good deal of similarity in colour; in short, the latter kind is not wanted at all. 3, Fisher Holmes is a Rose that but few specialists can grow well in pots, albeit the colour is good when it comes good. As this is the only "red" Rose given in the list of six, one wonders why so comparatively easy a grower as General Jacqueminot is omitted altogether. Failing this, I would unhesitatingly select either Capt. Hayward or Prince Arthur. In any case, Fisher Holmes is quite useless to a beginner. 4, Frau Carl Druschki I have never grown in pots, and, indeed, it is so much a novelty at the present time that it is doubtful if many can speak definitely concerning it. 5, Caroline Testout is a superb Rose for pots when once wood of the right character has been obtained by cultivation in pots. In other words, this kind is of little use until it has been eighteen months under pot culture. 6, La France is the best of the first six, flowering twice in rather quick succession when established.

My experience with Roses in pots under glass, and of the varieties similar to the above named, is that "Alec" should proceed as follows: First purchase in early October strong selected maidens, preferably on the Manetti stock. Pot at once into 8-inch pots, using rich soil, as advocated at p. 322, and plunge the pots to the rim in coal-ashes in the open. If the plants are dry at the root when received, soak them in water a few hours before potting up. The plants will be safe to the end of the year in the open, when they may be half shortened back and placed in a frame or even the cold-house. If the house is available, the plants may be pruned early in January and allowed to come away as slowly as possible. It were far better that these intended pot Roses should be grown quite cool under glass the first season, and by permitting only a single flower to develop on any growth, be not only receiving some reward for patient waiting, but also promoting and producing that earlier growth with restricted root area in pots that is assuredly the forerunner of success in the year ensuing. Often enough, maidens will produce a full crop of blooms six months after potting, but it is not prudent to allow the plants to do so; hence, I suggest one bloom to one growth. It is important, when growing pot Roses under glass of the H.P. character, that a long spell be given in which the plants may break into growth. Often enough, freshly-potted maidens, early potted, start to grow, and in this way pruning is forced upon one much earlier than the orthodox way would permit. It may be due to a large number of freshly-made roots in new soil, and the warm conditions of late autumn months. Be it what it may, it is folly to withhold pruning when the lower eyes are showing unmistakable activity. Pruned early and developed in a cool-house, I have had grand blooms from maidens less than five months in pots; therefore, I ask, why wait for eighteen months before seeing a good bloom? The longer the time between the pruning and the break from the wood the better will be the blooms, all else being equal. Duke of Edinburgh is a grand Rose for pots with slow and cool treatment, but it will not be forced, though it is recommended for such work again and again. But where Roses are not wanted before May I should always include this one, for it is a good keeper, of a magnificent colour—rich velvet-crimson—and, if need be, may be cut with 18 inches of stem. It has no fragrance; still, it is superb to look upon, and, though it is rare that maidens of it flower at all the year following

potting, yet the plants make such wood that the finest bloom may follow the next year when the wood is ripened off. Amateur Rose growers would be far more successful in growing their plants were they to realise the full value of annual early autumn potting for all H.P. Roses. E. J.

A FEW OF THE BEST AUTUMN-FLOWERING ROSES.

Now that there are so many Roses of value for autumn flowering, a selection of the best should prove of much assistance to all who are planting, mainly for the autumnal display. The lengthening nights, coupled with heavy dews, give to the semi-double Roses a wonderful decorative value, for such varieties expand freely, yet the developed blossoms remain on the plant for a considerable time, so that we have a more profuse display in September and October than we get in June and July from the same varieties.

No list of autumnals can be complete without the lovely G. Nabonnand, its very large petals, of a pale rose flesh tint, and long, elegant buds, combined with fine growth, making it one of the most desirable. Then how brilliant are the beds of the fragrant Gruss an Teplitz, some of the flowers having the beautiful velvety shading of Duke of Edinburgh, and, moreover, the coloured foliage is an additional charm to this glorious Rose. Camoens is not yet surpassed as a bright rose-pink for massing, and Marquise de Salisbury is certainly one of the brightest Roses and of even growth. Both of these last-named are extremely showy on the plant, and by pruning hard each season a more uniform growth and also a more regular blossoming are secured. Corallina, Enchantress, and Sulphurea are a trio of beautiful kinds, the first even more vigorous than the old pink Monthly, and it has huge coral-coloured petals and long, brilliant buds. Enchantress, with its half-drooping, globular flowers of a delicate creamy-yellow, and Sulphurea, clear and bright sulphur-yellow, are colours much desired. All three are really excellent, and should be largely planted for massing. Mme. Pernet Ducher is a never-failing source of delight, and Killarney gains more admirers each season. The old and well-tried Marie Van Houtto, its carmine-tinted petals being richer in autumn than in the height of summer, and Mme. Abel Chateaux are both vigorous and would make worthy companions. This latter Rose somehow compels admiration, even from those who cannot bring themselves to like these decorative Roses. What a strange taste, to be sure! But I have known individuals who can only admire a slow bloom of the perfect symmetry of an A. K. Williams or a Mrs. John Laing. Viscountess Folkestone is still one of our best autumnals, and it has a worthy companion in Grand Duc de Luxembourg. Marie d'Orleans is also first-rate, and as hardy as it is good. Papa Gontier has most shapely buds and smooth blossoms, and Mme. Lombard is also a fine autumnal Rose. General Schablikine and Comtesse Festetics Hamilton have a great future, for they grow and blossom most freely, and are always admired in the mass. Ma Tulipe will also please a great many, although nearly single. Its fragrant parent, Princess Bonnie, is one of the best things the American growers have ever sent us. Lady Battersea has a most lovely bud, the expanded flowers being not unlike those of Killarney, only rather deeper in colour. A refined, shapely, and brilliant Rose, too, is Liberty, and, above all, it possesses a powerful fragrance. Already this Rose seems to have recovered from excessive propagation, and I feel sure it will come to the front as one of our best dark coloured autumnals. What a fine contrast would be the charming White Lady, splendid always in autumn as in June. The La France race and, I might say, the Caroline Testout race, are well known as our best large-flowered autumnals, and the old and still unbested Souvenir de la Malmaison, with its sulphur-white sport, Kronprinzessin Victoria, give us of their beauty just now as they never do in the summer.

I could speak of the delightful Chinas, Queen Mab, Eugene Resal, and the rest, also some Polyanthas and others, but I have

already indicated quite a number that the grower may with every confidence plant largely, if his object be a brilliant mass of blossoms during the autumn days. ROSA.

ROSE BEAUTY OF WALTHAM.

It says much for an old favourite like Beauty of Waltham that in this, its fortieth year, the variety is found in the winning seventy-two that gained the champion trophy at the Temple Show. It is a very reliable Rose. It blossoms freely, and one may always depend upon a good flower, even if rather under-sized. Beauty of Waltham is a good autumnal for a Hybrid Perpetual. Unfortunately this group, collectively, does not rank as good autumnals when compared to the splendid Hybrid Teas, so that all that are above the average in this respect are most welcome. The colour is

NOTES AND REPLIES.

Rosa Pissardi.—This most interesting semi-double Rose was very fine during August. It is really one of the best August-blooming semi-doubles we have. Doubtless springing from *R. moschata*, it appears to be a hybrid, probably with the *Noisette*, which gives the variety its autumn-flowering habit. *R. Pissardi* and *Bardou Job* make a beautiful contrast, and flowering as they do together, an interesting effect can be secured. Several plants planted among a mass of *R. ferruginea* (*rubrifolia*) would be most interesting, the purple colour of the latter harmonising so well with the pearly-white blossoms of *Pissardi*.—ROSA.

Own-root Roses.—Where these are procurable in pots the present is an excellent time to plant out. Many kinds, especially the newer Teas and H. Teas, can only be raised

cannot say it is quite so profuse in flowering, but for arches and walls no better kind is to be found among apricot-coloured Roses, unless it be *Rève d'Or*. Its disposition to become bare at the base can be remedied by timely cutting back of the old growths, or by bending them about serpentine fashion, and, like all climbers, it pays for liberal treatment both when planting and during the growing period. As a standard it is also fine, just the one for an isolated specimen. If its growths pass through the winter unscathed, the following summer will see them studded all over with lovely buds. —ROSA.

Standard Rose Gloire de Dijon with long growths.—I have several standard *Rose-trees* of *Gloire*, old heads, and they throw three or four long shoots, 4 feet or 5 feet long, which look so unidly. Of course, these are valuable, but can you tell me what to do with them? In April I prune them down to about one-quarter their length, or one-third; but this seems such a pity. Then at this time of year they are unmanageable. I have tried tying them down, but now they are so tough they break. What is proper treatment of such to keep head of standard tidy always? I should like a drooping standard head.—A.

[If you refrained from pruning the long growths you would have them all studded over with lovely blossom the next summer. As you desire to have a drooping head, the growths require bending when young, and to do this best they should be cut hard back in spring, and as they grow train them to the desired shape, then the following summer you will have plenty of blossom on them. When once the head is formed with plenty of shoots bearing laterals, you may suppress the long annual shoots only, retaining such as you require the next year to replace any very old growths it may be desirable to cut out. Another plan, and one that answers well in the case of climbing Roses grown as standards, is to form a frame of wire beneath the head of the tree, and then partially coil the long growths in a semi-circular manner. Wherever the flow of sap is checked you will find plenty of laterals follow, and upon these, if shortened when pruning, some beautiful flowers will be produced. It will not harm the trees to cut these growths back at once should you object to the appearance of them.]

Climbing Roses on south wall.—I got some very useful guidance from you last spring through *HARDENING*, so I venture to come to you again. I have a gable wall, due south, in rather a draughty position, and I am at a loss to know what to grow on it. The house is painted, and there is an *Ampelopsis Veitchii*, also a white *Clematis*, not doing very well, on it. I have tried *China* Roses, but they are not a success. I think it is too hot. If you would kindly say what you think would do well I would be much obliged. I have tried *Wistaria*, but I fear it was kept too dry at the root. Please tell me what culture it requires?—FLOWER LARK.

[You should be able to grow several fine things on this wall, but it is necessary to thoroughly prepare the border in which you plant them. Wall plants, being fixtures, must be planted carefully, and you must see that there is a good depth of soil—3 feet, if possible. It would not be a great undertaking to remove the gravel subsoil, if such there be, to a depth of 3 feet, and replace with good garden soil in which vegetables have been grown successfully. As you fear your Roses have hitherto suffered from drought, this can be overcome by timely waterings, not mere sprinklings, but a good soaking now and then, afterwards mulching the surface with some short manure. Roses should grow well under these conditions, and good varieties are *Rève d'Or*, *Lamarque*, *Mme. Alfred Carriero*, *Souvenir de Mme. Joseph Metral*, *Waltham Climber No. 1*, *Reine Olga de Wurtemberg*, *Mme. Berard*, and *Mme. Jules Siegfried*. Other good climbers would be: *Pyraeantha Lelandi* for the most draughty position, *Bignonia radicans*, *Jasminum revolutum*, *Foraytia suspensa*, *Magnolia grandiflora* (*Exmouth* var.), and *Ceanothus* of sorts. A *Wistaria* should thrive well, but you must procure a well-rooted plant. It is best when purchasing to judge this plant more by its roots than its long growths. We have known plants sold with growths 10 feet to 12 feet long and but few roots, whereas we have procured plants whose roots went through the bottom of the pot, and although they had very little top, say about 4 feet, they quickly outpaced the longer plant. Always procure *Wistarias* in pots, and when planting break the pot, and then plant it with pot attached. They like a rather heavy soil, well drained, but we have never failed with them where roots were plentiful.]

Rose Beauty of Waltham.

right cherry-red, passing to rosy-carmine, and the fragrance is very sweet. The petals are somewhat imbricated, the centres characteristically folded over each other. This trait in hot weather preserves the flower, but it undoubtedly accounts for the paucity of seedlings from the variety. If taken in hand by the hybridist valuable hardy type would be produced. It is really remarkable how the Hybrid Perpetuals and themselves to crossing, and I marvel there is not more of it done, instead of so many others following each other in the track of hybrid Teas. We see in the variety *Ben Cant* on the fine bold petals of *Suzanne Marie* (*Madocanachi*) are given to a flower of the colour and form of *Victor Hugo*, the two kinds named being the parents of this coming *Rose*. *Beauty of Waltham* is a first-rate kind to grow as a standard, either outdoors or as a pot plant for the Rose-house. It is also good in bush form, the seedling *Brier* is the best stock for it, this continues to grow in autumn when the *lanetti* is practically at rest. Digitize Ros.

under glass, but if the plants were rooted early and have had several weeks in the open pits, they cannot fail to succeed well if planted now. The soil should be well worked, and where at all stiff a liberal admixture of grit afforded. When they become established then they can take liquid and other manure equal to their budded brethren. I have seen own-root plants in 5-inch pots quite equal in size to grafted plants of the same age; but even if the plants were a little smaller, provided the wood be hard, I would not hesitate to plant such.—ROSA.

Rose Mme. Berard.—This is one of the most beautifully formed Roses to be met with among the fast-growing climbing varieties. Its half-open flowers are perfect in colour and also in shape. The colour, too, is pleasing, the centre apricot with rosy-salmon exterior. Its one great blemish is mildew, the young growths often being sadly marred by this troublesome fungus, otherwise no more beautiful climber could be planted, and it is as free in growth and nearly as hardy as *Gloire de Dijon*. UN

OUTDOOR PLANTS

FLAME FLOWERS (KNIPHOFIAS).

THE Kniphofias, especially the forms of *K. Uvaria*, are amongst the finest of autumn-flowering plants. Large irregular groups give a very brilliant effect in autumn, and they

soils and conditions, and few plants are better adapted for picturesque grouping in the wild garden, where with a fairly open space and deep rich soil it forms large and very handsome groups. It is the most valuable of the known species, perhaps as much as 70 per cent. of the garden forms being traceable to *K. aloides*, either as seedlings or hybrids. The variety

after all the other forms are over; the flowers are greenish-yellow, only occasionally tinged with red. The var. *Saundersi* has bright green leaves and very rich orange-scarlet flowers; var. *longiscapa* has very long flower-heads, and is a most desirable form; var. *maxima globosa*, earlier than *maxima*, with globose heads of yellow and red flowers; var. *glaucescens*, large spikes of vermilion-scarlet flowers, shading to orange. This is a free-flowering plant, and one of the very best in heavy, rich soil. There are many more forms to be found in gardens, having been raised in recent years. Most of these are distinct and good.

K. BIRCHELLI.—The type, as introduced from the Cape, is a very distinct and beautiful plant. It is figured in the *Botanical Register*, tab. 1745, but this figure differs somewhat from the plant now in cultivation, which we take to be a hybrid or connecting-link between that species and *K. aloides*. The latter form has a purple-spotted stem, the flower-stalks being much shorter than in the type, and the plant dwarfier. It flowers soon after midsummer, and just between *præcox* and the other *aloides* forms. The leaves are bright green, firm in texture, 2 feet to 3 feet long, and tapering very gradually to the apex. Heads moderately dense, the flowers bright red, those on the lower

Kniphofia Nelsoni.

require no attention more than an occasional top-dressing of rich soil or well-rotted manure. Many of the species and varieties suffer from frost and damp, the latter more particularly, but this may be averted by a covering of dry leaves when the foliage begins to yellow in autumn. They are readily increased by division, by offsets, and by seeds, the last giving most curious results and many good varieties. The following are amongst the best of those in cultivation:—

K. ALOIDES, or *Tritoma Uvaria*, under which

præcox flowers much earlier than any other form of *K. aloides*, being in full perfection from the middle to the end of May. The leaves are broader than those of the type, not glaucous, the raceme shorter, and the stem only about half as long as the leaves. The flowers, with the stamens not protruding, are bright red, passing into yellow tinged red when older. The variety *nobilis*, which is very near, if not similar, to *grandis*, is a very robust and noble plant. The leaves are more distinctly serrated and deeper keeled. The flowering

K. aloides in a Scotch garden.

K. hybrida Obelisk.

end bright yellow. The style in this case protrudes, the stamens being included in the tube. A useful and very distinct plant, suited well for dry banks, etc.

K. CAULESCENS AND *K. NORTHII* differ from all other Flame-flowers in cultivation by their distinctly caulescent habit. From all the *Uvaria* forms *K. caulescens* differs also in its smaller size, glaucous leaves, short heads, and less curved flowers. Though less brilliant in colour than most of the other species, it is one of the hardiest species we have, with a very distinct and robust habit, flowering, as a rule, early, which is a specially welcome feature. It is a very striking plant for the rock garden, where it does well and flowers freely on dry slopes. Its cultivation, indeed, may be said to be the easiest, and it may be propagated freely from suckers and by cutting up the short stem. The suckers or offsets taken off in early autumn root freely in sand in a cold-frame.

K. COMOSA seems to be closely allied to *K.*

name it is even now known in many gardens, is perhaps the oldest, and still one of the very best of this fine genus. It is the Flame-flower of old English cottage gardens. It is an excellent border plant, suitable for all kinds of

stem is from 5 feet to 8 feet in height. The flowers vary from scarlet to orange-scarlet, anthers prominent. It blooms from the beginning of August to September. The variety *serotina* or *chloroleuca* blooms a month or so

pumila, and gives a very peculiar effect with its long, protruding style and anthers. It is much dwarfer in habit than the well-known *K. Uvaria*, the leaves much narrower, the flowers smaller, and of a uniform bright colour. The leaves are in dense rosettes, narrow, erect, and

an elevation of 4,000 feet to 5,000 feet above sea level. The leaves are 1 foot to 2 feet long, narrow, and distinctly keeled, with deeply grooved margins. The flower-heads are small, and the flowers of a bright orange-red. The plant is perfectly hardy and suitable for rock-

K. hybrida Triumph.

of a bright green, very pointed, and almost three cornered. The flowers are all drooping, in a dense oblong head, bright yellow, much narrowed or constricted above the base. The stamens and style are about twice the length of the flower-tube. A showy, but rather tender plant, flowering in September.

K. CORALLINA, a very fine robust hybrid between this species and *K. aloides*, is exactly intermediate between the two, and a very desirable plant.

K. FOLIOSA (syn. *K. Quartiniana*) may be said to be the counterpart of *K. caulescens*, but having distinct stems instead of being stemless. It is one of the most robust of the whole genus, and is easily recognised by its broadish leaves and protruding stamens. It was first flowered in England about 1881. The leaves are collected in a dense tuft on the top of a longish bare stem, 3 inches to 4 inches broad at the base, and tapering into a long point; green or very slightly glaucous, obscurely serrated. Stem stout, 1 foot to 3 feet high. The flowers, in a dense oblong head nearly a foot long, are bright yellow or tinged red. Native of the Cape, flowering in late autumn.

K. LEICHTLINI was named in honour of Herr Max Leichtlin, of Baden-Baden, who has done so much to furnish English gardens with rare and beautiful hardy plants. The present species is a native of Abyssinia, and requires protection in winter even in the south of England. It is, perhaps, nearest to *K. pumila*. Leaves in a dense tuft, about 2 feet to 4 feet long, spreading, dilated at the base into a broad, clasping shield, gradually narrowing to the tip, three-cornered, bright green, with entire margins. The flower-stems are from 2 feet to 4 feet high, the head about 6 inches long, flowers drooping, of a dull vermilion-red and yellow, stamens slightly protruding. The variety *disticha*, which is quite distinct from the type, is more robust, the leaves are broader, the flower-tube shorter, and the stamens decidedly longer. Two and even three heads of flowers of a bright deep yellow colour are produced on the same stem. Native of Abyssinia, and flowering in August.

K. MACOWANI.—A distinct type, differing from most of the other species by the reflexed segments of the corolla and dwarf habit at

eries; *rigidissima* and *maroccana* are garden names, and the variety *longiflora* has much longer flowers.

K. NELSONI has tufts of fine Grass-like foliage, about a foot in height, from which issue many flower-stems, 2 feet high, late in autumn. The flowers are a bright coral-red in colour.

K. NORTONI.—A species from Grahamstown, of undoubted hardiness in the neighbourhood of London. It is most nearly allied to *K. caulescens*, but the leaves are much broader, not keeled, serrulate on margins, flower-heads dense, about a foot long, the flowers pale yellow, only the upper half tinged red towards the tips.

K. ROOPERI is one of the best species in cultivation. It is nearly allied to *K. Uvaria*, but is an early or summer-flowering plant, the stamens being included in the tube, the flowers paler and less curved and the leaves broad and very glaucous. It requires a little protection during severe winters. It has a fine bold appearance when in full bloom, the heads from 6 inches to a foot long, and the crowded flowers of a bright orange-red, getting yellowish with age. The plant usually called *Rooperi*, flowering in November and December, is a variety of *K. aloides*.

K. SARMENTOSA is a distinct and very useful plant. It is readily distinguished from *K. Uvaria* by its smaller glaucous leaves, the edges and keel not serrated as in that species. The flower-heads are 6 inches to a foot long, cylindrical, the flowers red in the upper half, yellow or yellow tinged red in the lower. It is perfectly hardy and readily propagated by suckers. There is an excellent hybrid between this species and *K. Uvaria*. Native of the Cape.

K. TRICKI has large, glaucous, Yucca-like foliage, growing 4 feet to 5 feet high, with massive heads of bright red flowers, changing to yellow, and borne early in June.

Besides the above species we have now many hybrid forms, a few of the best of these being

OBELISK, which is very free flowering, the spikes attaining a height of some 5 feet, the flowering portion being about 15 inches long.

STAR OF BADEN-BADEN, with bronzy-yellow flowers, the spikes reaching to a height of 7 feet.

LACRISIS.—Of very strong and rapid growth, the colour a deep yellow.

TRICOLOR.—Very similar to *Obelisk*.

ORANGE.—Rich orange, a distinct shade. It is also very free flowering.

NOTES ON HARDY FLOWERS.

HEUCHERA SANGUINEA.—As a weather-proof flower this has few equals. The flowers seem to be quite indifferent to atmospheric changes, periods of great heat and heavy rains not dimming their brightness. Plants that came with me into bloom early in July were bright and attractive at the end of August. During that period we have had a lot of inclement weather—thunderstorms which washed the colour out of many hardy things, and drizzling rains, with brief spells of hot sun. Any hardy flower that will pass with undimmed beauty through such trials should be cherished. The best way to utilise this *Heuchera* is to plant in colonies of from three to a score of plants, as in this way its decorative worth is better realised. A top-dressing of leaf-mould or rotten manure applied in early spring will impart vigour, and so give strength to the flower spikes and colour to the blooms. There are, I find, some inferior varieties of this plant in cultivation; they have probably been raised from seeds and give no true idea of the worth of this *Heuchera*, the flowers being very poor in colour. The best form of it is *splendens*, which has very bright flowers, and there is another form called *robusta* which is much stronger than the type.

SAXIFRAGA HAWORTHII.—I am not aware if this Saxifrage is grown under any other name in this country. Up to the present I have failed to find it in any English catalogue of hardy flowers. I got my plant from Holland, where this species has apparently been grown under the present name for a considerable period. I find, however, that in the case of alpine the Dutch nomenclature is not very reliable; one is apt to get the same thing under

K. aloides grandis

several different names from different firms. Whatever the true name of *Saxifraga Haworthii* may be, it is a gem among rock plants, and certainly the best of the mossy section. It forms cushions of rather pale green verdure, about 6 inches high, the growth being dense y

packed and somewhat rounded at the top. As is the case with the Saxifragas generally, the young growths take on a brownish tinge in summer, but the early autumn rains quickly restore the fresh green appearance, and by the end of September well established specimens are masses of lovely verdure, in which condition they remain all through the winter. The pure white flowers are produced in such profusion as to smother the plants; in fact, I know of no other member of this large and varied family that can compare with it for freedom of flowering. As a pot plant for cool rooms or window ledges it should have great value by reason of its delightful verdure; it is attractive all the year round.

MONTBRETIAS.—Now that the fine hybrid forms raised by M. Lemoine can be had at prices that place them within the reach of flower growers generally, we shall probably see but little of the old *crocosmiaeflora* and *Potsii*, from which they are derived. The newer kinds are, according to my experience, as free flowering as the typical forms, and although some of them are dwarfier in habit, they are all sufficiently vigorous to give a good display in the open ground. Such kinds as *Phare*, *Etoile de Feu*, and *Potsii grandiflora* are very brilliant, and in *Drap d'Or*, *Pluie d'Or*, *Aurea*, *Solfatorre*, etc., we get very pleasing and uncommon shades of chrome, orange, and yellow. Some kinds, such as *Tigridae*, are beautifully spotted. By reason of their graceful growth and fine colours, these Montbretias are distinct from all other hardy flowers, and now that they are sufficiently cheap to be within compass of the modest purse they will undoubtedly find a place in gardens large and small. I should wish, however, to warn intending growers that except in the very warmest parts of Great Britain, these fine hybrid forms cannot with safety be left in the open ground all the year through without protection. It is when the ground becomes hard frozen to a depth of 6 inches that they suffer, and are either killed outright or are so weakened that their blooming capacity is destroyed for the coming season. Either the bulbs should be protected in some way, or they should be lifted and stored away in some cool place, planting out again about the middle of March. These Montbretias make fine pot plants, putting three good bulbs in a 6-inch pot.

J. C., *Byfleet*.

EXCHANGING GARDEN SOIL.

It is quite a common request that "I would like so-and-so grown in a certain part of the garden, such as Sweet Peas at a certain entrance door, or on a certain border. They have been grown there for many years; they look so well there, and although they have not done so well as formerly, at the same time I like to see them there and would like you to bestow some attention upon them." Experience, however, has frequently proved that no matter how good the cultivation may be as regards tillage, manure, and after attention, it must be admitted that Sweet Peas and many other similar subjects never do so well as when they are sown or planted on fresh ground. Here I have two doorways from the flower garden into the kitchen garden. Sweet Peas are regularly grown on both sides of each door, and I could learn that they had not been a great success for some years previous to 1900. In that autumn I had the soil where they were to grow taken out to a depth of about 20 inches, and about as much in breadth. This was wheeled on to a vegetable break, and the trenches were refilled with soil from the vegetable break; in fact, it was simply an exchange of soil. The result proved eminently satisfactory, and its annual repetition has been attended with equally good results. Considering the many disappointments with Mignonette and other seed not germinating freely, or Roses whose growth is not all that could be desired, it well repays the labour, which, after all, is not a serious one, as it simply means loading the wheelbarrow for two journeys. Mignonette is another favourite plant, and is frequently sown by garden entrances; indeed, no finer subject could be desired for such a position, and if the same method be adopted as with the Sweet Peas, it will be found that no plant responds to fresh soil more readily than does Mignonette. Turning to plants of a per-

manent nature—for example, Roses—it has been found advantageous to place fresh soil round their roots when beating up old borders, and, when replanting whole borders of Rose-trees, it is the most satisfactory plan to exchange the soil, if this is at all practicable. Here a border occupied by Hybrid Tea Roses was subjected to the treatment recommended for the Sweet Pea borders, and it is at the present moment one of the features of the garden. About three years ago my employers intimated to me that they would like Hybrid Tea Roses in this particular border, but they had been planted twice and had refused to grow. Accordingly a similar mode of treatment was adopted. The soil was wheeled away to a depth of 24 inches, the bottom well broken up, and the trench refilled with soil from the vegetable quarters. Naturally, this was a heavier undertaking; but here again any extra labour has been amply recompensed by the production of many large and fine Rose blooms of various shades of colour.

J. JEFFREY.

St. Mary's Isle, N.B.

IRRITATION CAUSED BY HUMEA ELEGANS.

A FEMALE patient of mine who has a particularly delicate complexion, has during the last few months been frequently suffering from vesicular eruptions on the nose and cheeks looking like impetigo. They quickly subsided under treatment, but as there was an almost immediate relapse she consulted a specialist, who diagnosed eczema and naturally ordered a course of arsenic. On June 7th I found her with a red, swollen face, the left eye closed, large vesicles containing clear serum on the cheeks, and a patch of eczema on the left side of the chin. She was greatly alarmed, as she supposed that she had erysipelas. Her temperature, however, was normal. She was unable to account for the attack, but first noticed it after playing ping-pong. She had not been handling *Primula obconica* as she was aware of its dangers, but she volunteered the statements that she had been feeding chickens with crushed bones and that she had noticed some irritation about the nose. The attack subsided in the course of a few days under *lotia plumbi antiseptici*. The first time she went out, at the end of the week when her face was well, she complained of itching of her right eyelid, and in the course of a few hours her face was as bad as ever. She then said that she had picked a leaf of *Humea elegans*, and had smelt it, and that she had been in the habit during the last few months of picking a leaf and rubbing it on her veil as she liked the perfume. The position of the rash was just where a veil would touch the face and the patch on the chin corresponded to the place where the veil is screwed up and tucked in. No doubt this had been the cause of all the trouble.

Humea elegans, a native of New South Wales, is frequently grown in greenhouses for the sake of its perfume and flowers. The leaves are not unlike those of the Tobacco-plant in shape but much more shiny, and they exhale a strong smell like incense. A leaf rubbed on my arm left a gummy secretion with a powerful smell and was followed by a bright red punctiform rash which lasted all day but caused little irritation. A gardener has told me that he has noticed his arms itching after moving the plants and that the gardener who gave them to him suffered from a severely inflamed face, which was ascribed to an irritating soap, but no doubt was due to the *Humea*. It is well known that many plants like *Primula obconica* are irritants, but that *Humea elegans* is one of them was new to me and may be a warning to others.

DR. HEARNDEN, in the *Lancet*.

NOTES AND REPLIES.

Californian Irises.—I should be much obliged if "S. W. F.," who wrote article, August 2nd, on Irises, would kindly give me full description and cultural details of *Iris tenuis*, *Iris Texas*, and *Iris hexagona*?—G. J. FARRER.

Lifting Daffodils (*Daffodil*).—The bulbs sent are very weak, and will not be improved in any way by your disturbing them now. It is much too late for this work, which should have been done in July, and the work of transplanting have been done this month. The

whits roots are new roots that are issuing earlier this year than usual on account of the wet season. The roots perish annually, and when thus dormant the bulbs should at once be lifted where this is necessary. If you have lifted the bulbs the only thing to do is to get them planted again as quickly as possible; to dry them now is courting failure. It will be quite sufficient if you replant the bulbs thinly without breaking up any of those with double crown, selecting a place not overdone with trees or shade, and planting 4 inches deep. Some grit may be added about the bulbs at planting time. It is now too late to lift the bulbous Irises.

Poppy Anemones.—I forward to you by this post a few blooms of my St. Bridget Anemone seedlings, sown in April last. They have had special culture, beginning with a very careful preparation of the seed-beds.—MRS. S. M. SWINNY, *Tobarcooran, Carmoney, Belfast*.

A beautiful gathering of these useful flowers, which can be had over such a long season. The colours range from pure white to the brightest scarlet.—ED.]

Patchy lawn.—Last autumn I had a piece of ground prepared for a lawn by levelling, after removing Apples and hush fruits. The spring was so cold that seed could not be sown till May 2nd. This has grown well. It was mown by hand at first, but latterly rolled and cut weekly with a machine. It looks a green sward, but on examination it is lumpy, with bare patches. Will these fill up? Or would it be well to sow a little seed now to take its chance of growing? Or would any top-dressing be advisable? I ought to say no manure was used at time of making lawn, trees having been regularly dressed for years. Can it be rolled with advantage this winter?—ANATHEA.

[You ought to at once give your lawn a good top-dressing of loamy soil, rotten manure, and wood ashes, and sprinkle some Grass-seed over it. You may roll it whenever the weather is mild.]

Primula rosea seed not starting.—I have had two packets of above, and have not succeeded in raising a single plant. The first lot was sown in February in pans, boxes, and open ground, and the second on June 21 and August 30, also according to directions. I should be much obliged if you could give me any idea of the reason of failure?—SIRLEBERT.

[In raising any of the hardy *Primula* family from seed, patience is necessary, as the seed often remains dormant for a long time, unless it is sown as soon as gathered, and it must on no account be placed in heat. A cool-frame is the proper place for the seed-pan. Some of your seedlings may appear this autumn, and in all probability you will find a great many will grow next spring. On no account throw away the soil in which the seeds have been sown.]

Worms on path.—I have a newly-laid gravel path around my garden, which seems infested with worms. Can you suggest a remedy for these, as they are continually throwing up the gravel and earth, particularly after a wet evening? I have rolled it several times, but this seems of no effect.—F. M. S.

[The presence of the worms is the truest indication of a badly made—that is, insufficiently drained—path. We hardly know what you can apply, inasmuch as in the very nature of things the worms work the soil that should not be there. Anything you may apply to one part will merely send them elsewhere. The only true remedy is to remove the underlying soil and replace it with rough gravel, clinkers, or even rough ashes. In such material the worms cannot work. Lime-water may bring many to the surface, but so long as the soil exists below the worms will of a surety find their way thither.]

Plants for pergola (*R. M.*).—The following plants would be suitable for spring: *Clematis montana*, *Wistaria*, *Jasminum nudiflorum*, *Rose Gloire de Dijon*, *R. Cheshant Hybrid*, as among the earliest of all to bloom; while for summer the material is abundant. What with Roses in plenty—*Carmine Pillar*, *Crimson Rambler*, *Alistor Stella Grey*, *W. A. Richardson*, *Mme. Bernard*, *Climbing Perle des Jardins*, and *Leuchtsterne*, all of which are very charming and free for the purpose, and may be augmented by such *Clematis* as *Jackman*, *J. superba*, *J. Mrs. George Jackman*, etc. For the later lot we would name *Clematis Viticella rubra* and *alba*, *C. lanuginosa nivea*, *C. Lord Wolseley*, *C. Fairy Queen*, *C. Beauty of Worcester*, *C. rubra*, *C. purpurea elegans*, *C. Anderson Henry*, *C. Gipsy Queen*, etc. To these could be added such as *Tropaeolum speciosum*, *Passiflora Constance Elliot*, *Solanum jasminoides*, *Vitis Cincinnatica*, *Lonicera aureo reticulata*, *Rubus Incarnatus*, *Joncium officinale*, *Lathyrus latifolius albus*, and *Polygonum Baldschuanicum*, one of the finest of modern

introductions. The beauty and value of these pergolas lie in the indiscriminate arrangement that tends to give a touch of Nature to the whole, therefore we advise the co-mingling of Roses, Vines, and Clematis, etc., throughout, rather than any plan that would keep the plants too much to themselves. The flower you send is *Salvia Iforminum*.

Plants for churchyard (*Clericus*).—You have omitted a rough idea of the size of the ground, which would have been helpful in respect to the trees, etc. There is ample room for the hardy plant borders as you suggest, and you cannot do better than plant such things as Michaelmas Daisies, Kniphofias, Flag Irises in variety and in plenty, Sunflowers, Rudbeckias, *Stenactis speciosa*, Day Lilies, Lenten and Christmas Roses, Lupins, Achilleas (the tall kinds), *Alstroemerias*, *Anemone japonica* in var., *Agrostemma*, *Campanulas*, *Delphiniums*, *Eryngium*, *Echinops*, *Armeria*, *Solomon's Seal*, *Verbascum*, *Thalictrum*, *Chrysanthemum latifolium* vars., *C. uliginosum*, *Statice*, *Trollius*, *Paeonies*, *Perennial Pea*, *Helenium*, with *Aubri-*

in again with about half the sod lifted. The borders for hardy things could be prepared by deep digging and manuring, and may be planted now, or the soil may be trenched up for winter and lie exposed, and planted in March or April, which is a capital time, and for not a few things, the best time. There is in this work ample scope for a good display, both in the churchyard and borders, and much will depend upon the amount you wish to expend on the whole. At the same time, we may mention, for such a purpose, that not a few of the more showy things are also the cheaper kinds. Again, you need only plant thinly, so to speak, giving the plants room to develop. For making a good show in the Grass some of the bolder perennials are excellent, and the attention required is reduced to a minimum.

Spring borders (*L. A. J.*).—Do we understand that you desire the spring border to be a permanent thing? If so, we think the Tulips may disappoint you after the first year or so, simply because these things require occasional

wards. Both the *Trillium* and *Cypripedium* will do in the cold-house, and prefer peat and moisture.

THE INDIAN MOUNTAIN CLEMATIS
(*C. MONTANA*).

BEAUTIFUL garden effects are created by the more vigorous members of the Clematis family when permitted to ramble freely over pergolas, trees, and bushes. The subject of the accompanying illustration, *C. montana*, is one of the most beautiful of the family, and when well established grows vigorously, soon covering a large extent of surface. Few more charming spring pictures can be imagined than an old evergreen, its branches hung with the ivory-white flowers of this Clematis, whose shoots have reached the topmost boughs, and hang in a white veil from its dark-leaved branches. When planting it is well to give this Clematis a good start by providing it with a deep bed of rich soil, especially if it has to struggle with the roots of trees or other strong-growing sub-

The Indian Mountain Clematis (*C. montana*) on bushes and low trees.

...tias, alpine Aster, alpine Phloxes, and other dwarf plants for the front. You have given no idea of what width you purpose making the borders, and without this we can hardly help you in greater detail. If we can help you further when you have settled some of the details, please writa again. If the room would admit at "E. E.," you could plant Yew-trees as an avenue. If not, then we suggest the fine-leaved Holly (*Ilex Hodginsii*), a splendid plant in any soil free from stagnant water. The best time for Holly planting is May and early June, but Yews would have to be planted in October or left to April. You had better tell us something of the area of the ground, roughly. In the Grass you could plant Walnut, Spanish Chestnut, and Limes. Not a few of the *Abies* are very fine when established. In the Grass many bulbs may be planted, as Daffodils, Muscari, Scilla, Anemones in profusion, Snowdrops, Crocus, Crown Imperials, Tulips, etc. These could be planted any time now, by lifting a sod of turf with mattock, slightly loosening the lower soil, and covering

lifting and sorting as well as periodical transplanting. You say nothing of Narcissi, a group generally to be preferred for permanent planting to Tulips. Many Narcissi may not only remain, but improve with years; with Tulips it is often the other way, unless lifted, etc. We think if you relied upon such Narcissi as Sir Watkin, Stella, Princess, Emperor, Horsfieldi, Cynosure, ornatus, and recurvus, together with Tulips of the Gesner group and others, and carpet with *Chionodoxa*, *Scilla*, *Snowdrop*, *Snowflake*, *Muscari*, *Fritillaria Moleagris*, *Anemones*, and *Myosotis dissitiflora*, you would obtain a good result. The *Silene* is probably *S. pendula compacta*. *Iris reticulata* is early March flowering and bulbous, and *Echinops* and *Eryngium* are quite late summer flowering. The group planting is one of the simplest yet most effective in results. It is a good plan, however, first to get an idea on paper of the principal participants, with colour and probable time of flowering. By this means the smaller items can be readily filed in on the carpet plants arranged after-

jects. When once established it is wonderful how it will hold its own even under seemingly the most disadvantageous circumstances, but to do so the roots must have undisputed possession of the soil when given now quarters.

Weather in Scotland.—We have just experienced last night (September 12th) 6 degs. of frost, and the flower gardens, which have only now begun to look their best, present a mournful appearance. I trust no one has been caught napping, as I have been, by failing to put the lights on a batch of *Cinerarias*. I have lost them all, and those that will recover will not regain their lost energy. This severe touch at this time of year is in keeping with the cold, raw summer we have had, and nothing better can be expected. *Dahlias*, *Begonias*, *Heliotropes*, *Marigolds*, *Cannas*, *Fuchsias*, and even *Asters*, are one black mass. It is interesting to note that while the plants named previously have been ruined, some *Geraniums* have resisted the frost. A sharp look-out will have to

be kept, however, and covers of a light nature got ready to protect Chrysanthemums, which have by no means all set their buds yet. This frost also warns us to put under cover, without delay, Callas which have been plunged outside, and Camellias also, if not already done. — D. McIVER, *Bridge-of-Weir, N.E.*

CHRYSANTHEMUMS.

SEASONABLE HINTS.

THE present season is curious in many respects, and there is some anxiety in the minds of many growers as to what the outcome of it all will be. Plants which were struck early in the year have done very well, and the buds have developed satisfactorily. Those growers, however, who delayed their operations have good reason to regret commencing in the spring; the buds have developed late, too late, in fact, to be of much use for the November exhibitions. The moist weather of the past summer has encouraged growth, the plants, as a rule, being much taller than usual. The tendency nowadays to retain second crown-buds has given us plants much taller than was the case some years ago, and, in quite a number of instances, the plants are exceptionally tall. A leading grower of the incurved varieties has quite a large number of plants from 9 feet to 11 feet in height, necessitating the use of extra tall steps to inspect the shoots and manipulate the buds. There is the promise—at least, from the collections of careful growers—of obtaining incurved blooms of exceptionally fine quality, and this can only be achieved by commencing the propagation of this type of the Chrysanthemum during December at the latest, stopping or pinching the resulting plants in March or April, and retaining second crown-buds, or those of even a later series, developing somewhere about the last week of August or the earlier days of September. For exhibition, it is now far too late to retain buds in the hope that they will develop blooms for the November shows. In the case of plants grown for decoration, however, terminal buds may be retained, and, under ordinary treatment, blossoms should result from these for the November displays. Terminal buds develop at a rapid rate, and, as the blooms from this bud selection are not by any means over-large, they are invaluable for cutting. Their colour, too, is usually good, and rarely are they known to show signs of damping of the florists. Keep a sharp look-out for insect pests. The earwig is one of the greatest troubles at this season, often eating out the points of the tender shoots with the buds in embryo. Inverted pots with hay or paper in them, and placed on the stakes, are a capital and ready means of trapping them. The pots should be examined each morning and carefully lifted. They should then be shaken over a vessel containing boiling water, or any other equally efficacious fluid for destroying them. As Bamboo canes are now used very extensively for stakes, it is just as well to point out how they harbour the earwigs. Those Bamboo stakes with hollowed-out stems afford an excellent hiding place, and old stakes may be slit down and often found to contain quite a lot of earwigs. For this reason, growers should fill the hole in the top of the Bamboos with putty or any other equally useful substance, and in this way minimise the risk of damage to the shoots.

HOUSING THE PLANTS is the all-important item of work at the present time. Too often this is deferred, and not infrequently the plants are rushed into the glass structure without the latter being in a fit state to receive them, or the plants ready for placing under glass. There are several little details, not the least of these being the proper cleansing of the greenhouse or conservatory preparatory thereto. If it be possible, confine the house exclusively to Chrysanthemums, as in this way it is much easier to give them proper treatment, without which the best results cannot be obtained. If necessary, take down the benches and stands and remove them outside. Proceed then to give the glass structure a thorough cleaning. Walls should be lime-washed, as this has a sweetening influence besides filling up cavities, which are too often the hiding-places of insect pests. See that the floor of the house, no

matter what may be its character, is rendered clean, also see that the ventilators are in order, and that the side windows open without any trouble. If the roof has not had a coat of paint lately, at least once, both inside and out, should it be gone over. By these means the glass roof is made waterproof, which is very necessary, as "drip," when the plants are in full blossom, may cause the loss of many of the prettiest and best flowers. Before taking the plants inside, see that all the foliage and weeds are removed. When releasing the ties made to the cross wires in the standing ground, observe the greatest care, otherwise many valuable shoots may be lost. Arrange the plants in the house so that the best effect may be gained. The group should slope from the tallest at the back to the shortest in the front. On no account crowd the plants. Dust with flowers of sulphur any plants affected with mildew. E. G.

ROOM AND WINDOW.

EVERLASTING FLOWERS FOR WINTER USE.

WHERE numerous tall vases require filling for the winter months and suitable flowers are not over-plentiful, various kinds of Everlasting Flowers and Grasses are useful, and make an agreeable change. Honesty ranks as one of the best; the shining silvery seed-pods when prepared are very showy and last a long time in good condition, and it is also valuable in the herbaceous border in early summer, when the purple and white flowers are freely produced. There is only one thing that tells against the growing of Honesty in the herbaceous borders for use during the winter—its untidy appearance after the flowers have faded and when the seed-pods are forming. The remedy, then, is to grow a batch of plants in some part of the kitchen garden for winter use only. With good culture Honesty grows from 3 feet to 4 feet high. The plants should be pulled up when thoroughly dry and hung up in a cool, airy shed to dry gradually for ten days, when the outer covering of the seed-pods can be easily taken off, leaving nothing but the shining silvery centre. They should be again hung up in the same quarters until required for use.

THE PEARL CUPWEEK (*Gnaphalium margaritaceum*) is valuable for winter use, but not often employed for this purpose. The flower-heads are produced on stout stalks from 2 feet to 3 feet long: the fully expanded blossoms have their outer petals white, the centre pale yellow; the unexpanded buds have a scaly appearance, silvery-white. The leaves are woolly, and should be stripped off when the stems are gathered, hanging the flowers up in bunches to dry gradually in a cool, airy shed. If laid in the sun they dry too fast, shrivelling the stems and discolouring the flower-heads. Beyond its value for winter decoration, this *Gnaphalium* is much appreciated as a summer-flowering herbaceous subject. The

HELICHRYSUM is the most common species of Everlasting Flowers, and probably the most useful of all, as it can be had in such a variety of colours from the bracteatum type, from pure white to scarlet-crimson, with innumerable tints between. They ought to be cut in a variety of stages, from small buds to fully expanded blossoms, to obtain the widest range of variety. Helichrysums are very suitable for small as well as tall vases, and for bouquets and wreaths. The same treatment is required for these as for the preceding in the way of harvesting the flowers.

RHODANTHES are valuable not only when grown in pots, but for winter use in a cut state; being slim in appearance, they lend themselves to tasteful arrangement in small vases for drawing-room decoration. Sown several seeds in 3-inch pots in March in a cold-frame, and afterwards planted out in rich soil in a warm position, they grow freely and flower profusely. They can be had in separate colours of carmine, rose, crimson, white, and yellow. The flowers ought to be fully expanded before cut, which should be done with as long stalks as possible.

WINTER CHERRY (*Physalis*) is not exactly deserving of being classed among Everlasting Flowers, although it is a capital subject

for winter decoration. The beauty of this plant consists in the bright red Cherry-like fruits inside a large inflated calyx. Under good cultivation stems bearing many fruits can be cut from 1 foot to 2 feet long, but for keeping during the winter should become thoroughly matured before being cut.

ACROCLINIUMS, rose and white, and the larger variety called grandiflorum of the roseum type, make capital winter ornaments for vases; being single-flowered on long, slender stems, they can be lightly arranged in a mass or mixed with other things. Seed should be sown in March in a cold-frame, the seedlings pricked out in light soil in a frame, and afterwards planted in rich compost in a thoroughly exposed situation. The flowers should be cut when young, as they retain their colours better in that state.

APHELEXIS of the macrantha type, cultivated as greenhouse specimens, are most useful in producing flowers for winter after they have served their purpose as exhibition plants during the summer. The flowers last a long time after being cut, and give pleasing shades of pink.

STATICE PROFUSA, another pleasing subject, is appreciated by many in a cut state for winter use, as blue flowers, even of the everlasting type, are rare. The flowers ought to be cut before they commence to turn pale on the plant, as the colour is better preserved and the flowers fresher too, consequently in better condition to stand the winter months in a cut state.

BULRUSHES of both the narrow and broad-leaved types make capital winter ornaments for large halls where an imposing group is required. Mixed with Pampas Grass plumes, Bulrushes have a good effect. When fully in bloom they should be gathered, being cut with long stems, as they are so much more ornamental in that way than when only a few inches long. Many kinds of

NATIVE GRASSES can be employed to give a winter effect if cut and preserved at the right time—when fully expanded just before the seeds commence to fall from the heads.

The flowering sprays of the now well-known Lace-flower (*Cypripedium paniculata*) and *Statice latifolia* are also very useful when cut and dried for winter decoration. The Sea Hollies (*Eryagium*), too, may be cut and dried in the same way.

GARDEN PESTS AND FRIENDS.

The Death's-head-moth (*M. Pinnell*).

—The insect that you send is the caterpillar of the Death's-head-moth (*Acherontia atropis*). These caterpillars, which are not uncommon, but never abundant, usually feed on the leaves of Potatoes, but they do very little harm, and will not injure your Chrysanthemums in any way. When fully grown the caterpillar buries itself in the ground and becomes a chrysalis, in which condition it remains during the winter.

CATERPILLAR (*J. Blackmore*).—The caterpillar you enclosed was that of one of the "Sphinx Moths," but it had tried to become a chrysalis on the journey and only partially succeeded, and it was, therefore, impossible to tell to what species it belonged, so I cannot say on what it probably fed. It is very seldom that these caterpillars are the cause of any real injury in gardens, for they are rarely found in any abundance, but each caterpillar will consume a considerable amount of leaves during its life.—G. S. S.

DESTROYING SLUGS (*A. W.*).—Freeing a garden from slugs and snails when they have been long left to breed abundantly is always a difficult matter, and it is more so when the garden is surrounded by hedges or similar harbour. Dressings of soot or fresh slacked lime are very efficacious in killing the pests if applied at the right time, and that is of an evening, when damp falls and the pests come out to feed. Then dustings of these powders are very destructive. Again, when Cabbage, Cauliflower, Lettuce, or similar plants are put out, and it is found that slugs eat them, if looked for at night with a candle hundreds may be caught and destroyed; that, too, is the time to use the soot and lime. If the pests harbour at the foot of walls or fences, straw salt freely and often there. Also get

gas-lime, break it fine, and use it in the same way, or freely about beneath hedges. Also, if it be strewn between rows of plants, but not on them, it acts as a great deterrent for a time. We do not advise the use of paraffin oil for the purpose.

Insects on Pear-trees (*L. Borae*).—From your description we should say that your Pear-trees have been attacked by the grubs of the Pear saw-fly (*Eriocampa adumbrata*). The grubs are commonly known as slug-worms. If the tree is bearing a crop of fruit, it is very difficult to advise a remedy. Syringing the tree with paraffin-emulsion or Tobacco-water and soft-soap are useful. When full grown, the grubs bury themselves in the ground just under the trees and between 3 inches and 4 inches below the surface. They each spin a thin, papery cocoon round themselves, in which they become chrysalides. The surface soil should be removed and burnt or buried, and replaced with good soil free from this pest.

Moss on walks.—For some time past there has appeared on the paths in my garden a curious green growth, after rains especially. I enclose a specimen, and shall be greatly obliged if you will tell me what it is and how to get rid of it? My garden paths are made of what is locally known as "shillet."—J. E. GRIMMIS (L. COL.)

[The green growth on your garden paths is one of the algae belonging to the genus *Nostoc*, by which name it is commonly known. These gelatinous masses are composed almost entirely of minute chains of spores. I should scrape as much off as I could and then water the paths with a weed-killer. You would find 2½ lb. of lime and 2 lb. of sulphur, boiled together in 10 gallons of water, after it has settled pour off and use the clear liquid, or 1 part of sulphuric acid (oil of vitriol) mixed in 30 parts of water, useful, or the mixture sold under the name of "weed-killers."—G. S. S.]

Fungus in Vine border (*B. Z.*).—The matter which you find in your Vine bed seems chiefly composed of the mycelium or spawn of a fungus. What the fungus is I cannot say, as the spawn of fungi are so much alike, and I cannot find any of the spore-bearing part. I am afraid that there is no chance of destroying it by means of any fungicide, as if one were applied in sufficient strength to kill the fungus, it would destroy the roots of your Vines. I should open up the bed and take away all you can find, and remove the Rhubarb plant, which cannot be a good neighbour for the Vines, as it takes so much out of the soil. At the same time you will be able to see if the roots of your Vines are healthy, and if they are infested by the fungus in any way.—G. S. S.

VEGETABLES.

SHALLOTS.

The Shallot is one of our best and most wholesome vegetables, useful alike for soups, salads, and other purposes, and it makes one of our best pickles. It is, in short, in every-day use, both in the kitchen and in the pantry. The light-coloured or true Shallot, an excellent

True Shallot.

which much resembles a small Onion. The bulbs do not keep so well as the true Shallot, and commence to grow sooner in spring. The Jersey Shallot flowers and seeds pretty regularly, the seed exactly resembling Onion seed; indeed, in all the characteristics of its growth the plant is an Onion, and has nothing to do with the true Shallot.

CULTURE.—In order to grow Shallots well and free from disease, never apply fresh manure to the ground on which they are to be grown. In autumn, or early in winter, trench up and ridge a piece of ground for them that has been manured the previous season for some other crop, and fork it over in frosty weather in order to get it sweet and well pulverised. Level it down, and plant the bulbs in February; but never, by any means, bury the bulbs too deep, nor plant them in very loose soil, for they are very subject to canker and mildew just when in full growth in May if damp gets down between their partings or claws, and, on account of these attacks, they are almost always scarce and dear. After levelling the ground stretch a line at distances a foot apart, with one foot tread the ground along the line only at planting time from end to end, then just press the bulbs on the surface, and place a pinch of fine cinder ashes on them to keep worms from them. In March, when the surface becomes dry and mellow, tread between the rows with both feet, so as to make the ground as firm as possible. This will raise the rows of bulbs a little above the general ground level. Then just clear the loose earth away from the bulbs, which will now have pushed forth roots, with the hand or small hoe, so as to allow them—i.e., the bulbs—to stand quite clear of the ground. Thus situated disease, mildew, or failure is scarcely possible; on the contrary, good, healthy, sound, firm crops are obtained. Plantations of Shallots may be made in October or March; but late in February or very early in March is the best season, and the crop may be taken up and stored whenever the leaves die down, or, if not then, in autumn. After being well dried the roots should be hung up in nets or laid thinly on shelves, or even hanked in an airy loft, or wherever the Onion crop is stored.

VEGETABLES FOR THE WINTER.

If a constant supply of the best vegetables is to be kept up through the year, then considerable thought is necessary, and at no time more so than during the autumn. Evidently the crop of Potatoes will not be heavy, and this will cause more demand for other vegetables, more especially when the spring comes. This being so, every effort should be made to begin the winter with a good stock of green vegetables and roots. Many growers at the beginning of winter think they have an enormous supply, but before new crops are ready they find this is not so, especially should the winter be a severe one.

If thought is given during autumn, much may be done by husbanding present crops and using those things that will not keep. After this cold, unless summer many crops are much lighter than usual. Runner Beans in our garden are not more than half the crop generally seen. The same holds good with dwarf kinds. By going over these frequently, gathering them when they have attained to their full size, and standing on their ends in big saucers in a cold place they keep fresh a long time, and extend their season considerably. Peas, again, should be gathered frequently. I find them keep best when laid in a damp place, placing a cloth over them. My Peas never were better till the end of August, when the cold storms and longer nights prevented their filling. If frost keeps off I shall have a supply till the end of October. Now, middle of September, Autocrat is my best kind. Marrows should be treated like Beans. Spinach should be used freely, gathering only the large leaves first, and where New Zealand Spinach (a most useful kind) is grown, it should be used till destroyed by frost. I have had this till late by covering on frosty nights and growing in Asparagus alleys, the Asparagus foliage keeping off the frost, unless very severe.

Only the whitest Cabbage should be used now. Brussels Sprouts are often begun too late, these ought not to be needed till

Cauliflower is well nigh over. I have a nice patch of French Horn Carrots, which will be ready when summer vegetables are over. Turnips will be abundant. When there is a glut I have them stored, allowing the late ones to grow while these are being used. All the big-necked Onions should be used first,

False or Jersey Shallot.

holding back the largest and best, as these are useful for stewing. Give every attention to Celery in the way of feeding and earthing up, as this is valuable in winter for stewing. Roots of all kinds should be preserved. With a good stock of Seakale Roots and Asparagus for forcing, there should be no scarcity till spring. J. CROOK.

Tomatoes in small houses in winter.—Attempts made to grow Tomatoes in small houses where other plants are kept during the winter are seldom attended with anything like success; but there is always the temptation at this time of the year, if the summer crop has turned out well, to try what one can do in the winter, and, as cuttings strike easily and quickly, all things go on well until towards November, when fogs and cold weather set in. It is about that time when the grower of Tomatoes is face to face with the difficulty of keeping up sufficient heat, and finds out that winter culture is far different to summer, when solar heat plays such an important part. Where it is intended to grow them, they should be given a house to themselves, as mixed up with Pelargoniums, etc., they become drawn, whilst the extra heat needed for the Tomatoes is not wanted for bedding plants, and so both are spoiled. Growing a few plants on the long rod system in a separate house is, I am convinced, the right course to adopt.—LEMCHEST.

About Cucumbers.—In spring and summer, more especially when it is very hot, the demand for Cucumbers is great. Frequently growers fail with them in frames from keeping them too moist and close, whereas, if they gave them more air, they would grow more sturdy and not get infested with fly. I expose the plants to the open on warm afternoons, shutting up at nightfall, watering in the morning only. In this way the growth is sturdy. I find some kinds are more suitable for frames than others, and during the last two years I have grown many kinds. I find a good stock of Rochford's hard to beat, either for frames or for house culture. This year I grow this, Marvel, and Lord Roberts side by side in a Fig-house. The two former are of a similar type, but Lord Roberts is a fine, long, smooth kind, growing to a length of 24 inches, and is a fine exhibition kind. Opinions differ regarding the flavour in Cucumbers. I never could find much difference in kinds when grown well and quickly. Recently I had a gentleman in the seed trade staying with me, and one night he wished to try those three kinds together with salt only. He considered Marvel and Lord Roberts the best; most greengrocers prefer Rochford's.—J. CROOK.

Photographs of Gardens, Plants, or Trees.—We offer each week a copy of the latest edition of the "English Flower Garden" for the best photograph of a garden or any of its contents, indoors or outdoors, sent to us in any one week. Second prize, Half a Guinea.

The Prize Winners this week are: 1, Mr. Geo. E. Low, Dublin, for Solanum jasminoides; 2, Rev. J. S. Griffiths, Gainsborough, for Rose Dejoncques.

FRUIT.

PEACH ROYAL GEORGE.

FEW varieties of Peaches have such a good record as this. Royal George is one of the best known and is largely grown in all parts of the kingdom. For forcing, Royal George rarely fails, and it will stand more heat than many of the earlier kinds. This variety forced yearly sets grandly. It does not drop its buds like many others and is not at all fastidious as to the position given. It makes a grand back wall tree, and, provided the wood is not crowded, the fruits are large and very sweet, with the distinct flavour so much liked. The fruits, given the best culture, are medium sized, skin pale, speckled with red in the shade, and marbled, as it were, near the stalk, the portion exposed to the sun being a deep red. The flesh is a pale yellowish white, the portion near the stone very red. The flowers are small and the leaves are without glands. In the open it may be termed a midseason variety, ripening at the end of August on a warm wall.

In cold, wet soils on open walls this variety is not reliable, as it mildows badly, no matter how well treated as regards food. Even in light soils in the most favoured localities at times it fails badly. Doubtless this failing is caused at times by the stock not suiting the variety. With much rain or dull, cold weather the trees are often suddenly attacked, and, unless means are taken to check the mildew, it so badly disfigures the fruit that it is not presentable at table, and the trees have a wretched appearance. On the other hand, in even heavier soil, but in an elevated position near the sea-coast, trees have never been attacked. In the Thames valley it rarely escapes.

THE PLUM CROP.

MANY disappointments have been experienced this year in regard to the Plum. In the spring there was every indication of a bounteous crop, but the vicissitudes of the year have been so many and varied that the results have not come up to expectation. The dearth of Plums is not a universal outcry, for in some favoured districts there is abundance, judging by the quantities of the common kinds that find their way into the markets. Choice Plums, however, seem scarce, and it is not in the least to be wondered at, when the amount of blight which infested the trees in early summer is remembered. Frost and cold east winds did irreparable damage to the open flowers, and standard trees, where at all exposed, suffered severely from this cause alone. Taking into account the extremely untoward nature of the season, there is reason for congratulation in the extent and quality of wall-grown Plums. As a natural outcome of the cold spring and dull summer all Plums were later than usual. Sorts that in some years I had been able to gather the first week in August were not ready until early in September. At the end of July there were no apparent prospects of ripe Plums for Bank Holiday shows, but Early Rivers', Peach Plum, and Orleans came to the rescue. That useful early Plum, Oullin's Golden, did not ripen for some days later; indeed, it was in use till the end of that month, while of Jefferson's and Kirke's I had not a sign of a ripe fruit in mid-August. Transparent, Lawson's and Guthrie's Gages, Pond's, Victoria, Prince Englebert, Diamond, Monarch, and Grand Duke have each cropped fairly well. Coe's Golden Drop bears less than half a crop this year, and Coe's Late Red is almost an entire failure. Blue Imperatrice has cropped somewhat more heavily, and Reine Claude de Bavay, Bryanstone's, and Golden Gages are much below the average. There is a marked absence of sweetness in many Plums this season, which is nothing less than may be looked for when it is remembered there has been little sunshine. Though a south wall is deemed necessary for producing the first crops of all choice fruits, the aspect does not, according to my experience, provide in Plums a gain of time over a west or eastern one. In light Plums there may be a somewhat brighter colour if there is not too much leafage to shade the fruit. Black varieties do not seem favoured at all in early

ripening on a south wall, and there is not much to choose between east and west exposures. I have not found that the lighter weight of crop has materially increased the size of the fruits, though naturally this would be expected.

W. S.

THE TREATMENT OF MELONS.

THE weather, up to the middle of September, could not be called at all favourable to Melons, seeing that they enjoy an abundance of solar heat from the time the plants are put out until the last fruit is cut, as, in the absence of sun, it is well nigh impossible to get fruit of even passable flavour, and a Melon deficient of this is very little better than a Marrow from the open garden. Plants now swelling their fruit require the greatest care and attention, as the days are fast drawing in, and, consequently, the sun has less power to assist in ripening the fruit. Endeavour to maintain a night temperature of about 70 degs., with an advance of 10 degs. or 15 degs. with sun-heat when full ventilation is afforded, increasing it gradually from when the thermometer indicates 78 degs. While ventilation is an important item with Melons, water at the root as well as overhead syringings is doubly so, especially during the latter part of September and succeeding month.

much sun-heat as possible after 2 p.m. to finish the same, covering the glass with a mat at night now it is inclined to be a bit colder. Plants in heated structures require to be closed about the same time, with plenty of moisture about the walls and paths. When ripening approaches less water at the root and moisture about the house or frame should be maintained, and a chink of air at all times. Of

VARIETIES there are many, each grower having his favourite, some preferring green-flesh, others scarlet. I prefer the scarlet-fleshed kinds, and consider Sutton's Scarlet an ideal Melon for a gentleman's table—rich in flavour, good setter, and strong constitution. From three to four fruits should be allowed each plant, then nice serviceable fruits, three or four to each, will be forthcoming if the plants have been well cared for. Hero of Lockinge, Triumph, Emerald Gem, and Earl's Favourite, are all excellent-flavoured varieties, with pale or green flesh. EAST DEVON.

NOTES AND REPLIES.

Scarcity of Apples.—It is many years since there was such a scarcity of good home-grown Apples. In this locality the crop of Pears is above the average, while in the same garden there is not half a crop of Apples.

A good all-round Peach (Royal George).

Test the soil the plants are growing in each day, and do not apply any at the root unless you are really convinced that the soil is well on the dry side, as many a crop has been lost through applying water indiscriminately at this time of year. On dull days overhead syringing should be discontinued, and even in bright weather it must be light, or the water will run down the bine on to the soil and cause canker to set in very soon—in fact, this will happen at any time throughout the summer unless care is exercised in the matter. Dusting with freshly-slaked lime on its first appearance will generally check it, but let the stems be examined every few days, rubbing fresh lime on if the malady appears likely to extend. In watering it should not reach the stems within 2 inches or 3 inches. Plants in pots, of course, require watering much oftener than do those planted out on mounds.

FEEDING THE PLANTS while the fruit is swelling must not be neglected, and I find no better manure than a pinch of Peruvian guano, squeezed up in the water—weak in preference to strong doses should be the order. Those who rely upon hot-bed frames for their supply must have had an anxious time of it this season, and the plants will have required much less water than is usually the case; and should there be any fruit still to ripen in such frames or cold-pits, it will be necessary to husband

Only the fruits on the top branches swelled out to a good size, and all the lower limbs had small, deformed fruit. This was especially the case with all the soft Codlin Apples of the Lord Suffield type, that did not perfect a quarter of a crop. The greatest failures about here were the highly coloured dessert sorts, of which the Devonshire Quarrenden was the most conspicuous, as the trees had in most cases not a single fruit on them. Those growers who have had a moderate crop this year have realised more profit from them than they did from last year's over-abundant crop, as they have had a ready sale for even the windfalls.—JAMES GROOM, Gosport.

Propagating the Mulberry.—I am about to saw off a branch of a Mulberry-tree, and should be glad of instructions as to making it root. I have read before that a branch will strike root if planted, but have tried it several times without success. When should it be cut off, how planted, how treated? Also, how thick and how long a branch?—A.

[If branches of some size are used, let these be cut off early in February and inserted a foot deep where neither sun nor wind can freely penetrate. Envelop the stem above the ground level with Moss, all but the upper pair of buds, in order to check evaporation.]

Grapes shanking.—I am sending some Grapes, and shall be glad if you will inform me why some of them have gone off and not ripened? The Vine has been planted about three years inside a greenhouse.—EVA, Oxford.

[Your Grapes are what is known as "shanked," brought on by the roots getting

into a cold subsoil or the border becoming sour and sodden, the young roots thus being destroyed. Another very probable cause is overcropping, which, from the poor colour of several of the berries, is in your case a very likely one.]

GARDEN WORK.

Conservatory.—For the cool conservatory, hardy plants, such as Stocks of the intermediate or East Lobbian type, are useful in spring. Forget-me-nots, potted up now, are charming early in the spring in pots, and are nice for filling small vases. The flowers come on longer stems when grown under glass, and the colours are brighter and have a fresher, cleaner appearance. White and other Pinks, such as Her Majesty and Anne Boleyn, are very useful for pot culture to flower in April and May. This they will do without much watering. Canterbury Bells, strong plants potted up now and kept in cold-frame till the new year, and then helped with just a little warmth, are very bright and effective in April or earlier. Rhedodendrons and Tree-Prunies are bright in April with cool-house treatment. Hybrid Primroses, potted up now into 4-inch pots, will flower in the winter. I have had pretty groups of them arranged in Moss in a cool house, and they are useful for filling small stands in the drawing-room. It is like bringing a breath of spring into the house to see Primroses when the snow is on the ground. Violets, again, are very attractive when well potted in pots. We used to grow Tree-Violets with double flowers in the winter years ago, but these have been lost sight of. Now we go in for the long-stalked flowers. Princess of Wales and Admiral Avonlin when well done in 5-inch pots are very charming. Of course, they want proper treatment. Cuttings of the old shoots planted now in boxes will root during winter, and, if planted out on a bit of good land, kept free from weeds, and, if necessary, mulched and watered during summer to keep down red-spider, which are partial to the foliage, they will be ready for potting up early in September, and may be stood on a coal-bed for a time, till the roots are working into the new soil. It is an article of faith with many of us that we must not expect a plant to do its best in the way of flowering till the roots have pretty well occupied all the soil, and then, when the roots are abundant, we can feed with liquid-manure in a moderate way to bring out the long-stalked flowers. One need not have a very high temperature to have a supply of flowers if the right means are adopted and the right plants selected. Mignonette, sown in August and again in September, and grown on shelves near the glass after the middle of September, will be very sweet at Christmas and later. Of course, Mignonette can be had earlier, but there is a freshness about the Mignonette grown under glass that is absent from the plants that have borne the heat of summer.

Stove.—There will soon be a demand for stove flowers for cutting, and to a certain extent this demand will be met by pushing on the Poinsettias, Begonias, and Euphorbias. Both the Euphorbias and Poinsettias may be planted out and trained up walls, if suitable positions can be found in the stove or warm-house, and a much better result, so far as flowers for cutting are concerned, obtained. Then there are still a few trusses of gorgeous blossoms on Allamandas, which last a good while in a cut state, or at least other flowers will continue opening, and form a succession. Eucharis Lilies, several forms of Vinca, including rosea and alba, and Epiphyllums that have been ripened in the sunshine will soon show flower-buds when brought into heat. Gardenias well ripened will respond to warmth and moisture. There are always a few Orchids in bloom among the Calanthes, Dendrobiums, Ophrys, Oncidium, and Cypripediums, etc., which may be managed in a mixed collection.

The Peach-house.—The fruits will all have been gathered even from late trees under glass now, and the condition of the wood examined, and all old wood which is not likely to be wanted for laying in had better be cut

out. No benefit will be derived from its presence, and the young wood intended for next year's bearing wants all the sun and air to be obtained in a season like the present. Another important matter is to make sure the borders are moist enough. The autumn is the time when the finishing touches are given to fruit-buds. If the roots are too dry the buds will be poorly built up, and will probably fall in the spring. Any over-luxuriant trees may have the roots lifted, and any tree which has done its work and does not now bear good fruit may be removed and the border prepared for the next tenant, which may be planted as soon as the leaves are falling. In most places young trees are kept in training for filling vacancies in houses. Those who are thinking of planting a new house or renovating an old one should be making preparations now. The best soil is a good sound, rather adhesive loam from an old pasture which has been fed off by sheep. The borders must be perfectly drained, and if the subsoil is bad the roots should be kept out of it by placing a layer of concrete on the bottom sloping towards the front, and on the concrete 6 inches of brick rubble should be laid. This makes the best possible job of it, and though the expense is considerable where permanency is desired, it pays to do work well.

Mushroom-house.—It is desirable to have a Mushroom-house in every garden, as so much besides Mushrooms can be grown in it. At this season beds should be made up frequently, because if the house is pretty well filled up in winter, the warmth from the fermenting manure will keep up the temperature. If we take 55 degs. as the mean temperature required, it may fluctuate a little both upwards and downwards without doing any harm. There are several things which must be insisted on in Mushroom growing. The manure must be from a stable where the horses have hard food, and where the manure from a sick horse is not included, and should be in a reasonably fresh condition. It is an advantage when the manure is fresh to mix about a fifth part of its bulk of good loam with it, thoroughly blending the whole together. This saves time in the preparation, as once turning will suffice, as the soil absorbs the moisture and keeps down the strong heat, and I have generally found such beds very prolific and last longer in a bearing condition. Of course, good, new spawn is absolutely necessary, and in making up the beds firmness is essential to free and continuous bearing. A covering of hay or litter keeps in the warmth and moisture.

Window gardening.—The boxes outside are now past their best, and should be refilled for the autumn and winter. Where one has small Chrysanthemums coming into bloom, they should be used to give an autumn display, and the winter furniture, either shrubs or other plants, introduced later. Spring-sown Lansies are coming into bloom now, and will be a nice change for winter without the shrubs. Wall-flowers and Forget-me-nots are sweet in spring. I do not care much for the average kind of shrub used, as they soon get brown and seared.

Outdoor garden.—Tidiness in the garden is important; in fact, one does not feel comfortable where disorder is the rule, even though certain plants may be in a thriving condition, and at this season, when dead leaves are falling about and flowers are fading, there is a good deal to do in keeping the plants in a thoroughly enjoyable state. Late-sown Astors are very fresh and nice, and can easily be moved with balls of earth without injury. If a bed of Victorias, or, for the matter of that, any kind of Aster, is sown thinly outside early in May, they will be very useful for filling beds now or earlier. The early-flowering Chrysanthemums, especially the different forms of Marie Masse and the old favourite, Mme. Desgrange, of which there are several varieties, are very bright now, and are useful for cutting. This has not been a good season for very tender novelties in the flower beds; but I have seen the plume-flowered Celosias effectively used in several gardens this summer. I bedded these out a good many years ago, and in favourable seasons they attracted much attention. Balsams are also very effective bedding plants. The best way of using Balsams is to plant them in

a good-sized bed a yard apart, and have a groundwork of some low-growing plant. Verbena or Heliotropes kept low are doing well with a band of Koniga variegata round the outside. Tender plants outside must be lifted and potted in sandy loam, with a little leaf-mould, and stand prepared at a moment's notice to be placed under cover. Carnations should be planted when the soil is dry on the surface. Lay down and repair lawns, either with seeds or turf.

Fruit garden.—Root-pruning may be done now; this is best done in a tentative way, not all round the tree at once. I am partial to the use of lime on fruit land. Gas-lime in moderation, say, a pound to the square yard, may be used any time with benefit to almost any kind of land. If more lime were used there would be less trouble with insects and millwigs (termed blights). Soot, also, is a good and cheap stimulant. All fruits are late in ripening, and the late Apples and Pears must hang till quite ready, or they will shrivel. Everything is quite a fortnight late, though a fortnight's dry, sunny weather would fetch up arrears; in fact, sunshine is wanted to ripen the wood. The early planting of Strawberries is important if a crop is wanted next year. Even if runners only are required, the young plants should be planted early enough to get established before severe frost comes. A mulching of good manure on old plantations will have considerable value now in plumping up crowns. Of course, old plantations must not be left till they have parted with all the vigour. Except in the best managed gardens, Strawberries are left too long in one position. Old worn-out wall trees should be cleared away and the site prepared for the young trees. It is a good plan to always have a few young trees, so that we can fill vacant places with young trees coming into bearing. Young Peach-trees which are making too much wood under glass may have the roots carefully lifted now.

Vegetable garden.—The seed-sowing outside is over for the season, but inside, where warmth can be given, French Beans of a dwarf early kind may be sown in pots, five Beans in a 6-inch pot, and kept near the glass in a night temperature of 80 degs. or so. If very early Asparagus is required, a row or two of very strong plants may be cut down ready for lifting when the hot-bed is ready. For early forcing, the best roots are those which have been grown specially for the work, and from which nothing has been cut. They are more vigorous, and require less heat to start the crowns. The roots should be from four to five years old from the seed. Clear off all exhausted vegetables and trench the ground. Fresh manure may be trenched into heavy, holding land now, but light, porous land should not be manured at this season. More lime might be used on vegetable and fruit land with advantage, especially newly broken up land where insects are numerous. In the latter case gas-lime, 2 lb. to the square yard, will do good, and if the land will lie dormant the quantity of gas-lime may be increased. This is a good season for making up Mushroom-beds for winter supply. Very often good Mushroom-beds are grown in sheds without artificial heat, and where the sheds are large and the beds numerous the heat from the beds will keep the requisite temperature; but there should be a regular temperature of 55 degs. to ensure a regular supply. Flimsy, badly constructed sheds are not suitable for winter Mushroom-beds, as in cold weather the temperature falls so low. Cucumbers will now be growing freely in the warm-house, and the leading shoots should be permitted to grow well up the roof before being stopped. E. HUNNAY.

THE COMING WEEK'S WORK.

Extracts from a Garden Diary.

September 29th.—More time is given up now to general tilling up; the mowing machine still has to go its regular round, and faded blossoms and dead leaves must be removed. But among the debris of autumn many hardy flowers are lovely in their freshness. Bold masses of Budbeckias, Starworts, Japanese Aconites, Sedum spectabile, and early-flowering Chrysanthemums are very effective. Cactus

and other Dahlias have up to the time of writing escaped the frost, which has not yet been very severe. We have been busy getting plants inside, as we cannot trust the weather now. Of course, we are always prepared to cover up anything tender.

September 30th.—With the exception of two trees of late Peaches which are scarcely ripe yet, the Peach season is over, and we are now cutting away all wood not required for filling up the trees next season. This hastens the maturation of the wood, which is most important. Trees that were mulched in the early summer, when the weather was dry, now want the remains of the autumnal sunshine on their roots, so the mulch has been raked off and removed. Exhausted vegetables, such as Peas and Beans, have been pulled up.

October 1st.—Azaleas have been received from Belgium and firmly potted in small pots as the roots can be comfortably got into, and placed in cool-pit for the present. One of the best forcing Azaleas is the Deutsche Perle. The best Spiræas are grown in Holland, especially in a dry season, and they are surprisingly cheap, but the carriage is heavy; in fact, the carriage costs more than the roots. The Dutch growers do not trade fair, as after selling all the bulbs they can in the trade, they immediately swamp the market with the surplus bulbs.

October 2nd.—Referring again to the heavy importations of Dutch bulbs, many of our home growers are growing certain kinds of bulbs quite as well as the Dutchmen, especially Narcissi of all kinds. These, in fact, are better than the Dutch roots this season, and they are much cheaper. Just finished lifting Potatoes, and found very little disease. Several frames have been filled with cuttings of choice shrubs. Half-grown Lettuces and Endives are being planted in cold-frames for winter.

October 3rd.—Shifted Cinerarias and Primulas into 5-inch pots. Cyclamens are now placed in light house where a little heat can be given. Herbaceous Calceolarias have been potted singly into 3½-inch pots, and are at present in cold-frames. Cucumbers in houses are growing freely and showing fruit. At present our supply is drawn from frames and pits. Apples and Pears are gathered as they ripen.

October 4th.—Violets have been placed in frames and a few potted in 6-inch pots. Tree-Carnations are showing flower in cool-house; a little fire will be used now. Scarlet Salvias in flower are moved to conservatory. Potted Spiræas and Dielytras for forcing; will be kept in cool pit for a time to make roots. Shifted on young Pteris Ferns. Planted out Carnations in beds and borders. Passed Dutch hoe through rows of Spinach, Onions, and Lettuces. Spinach has been thinned to 4 inches apart.

BIRDS.

The Chaffinch (*Fringilla œlebs*).—In its wild state this handsome bird subsists upon a diet of seeds, fruit-berries, and insects, feeding its nestlings upon the latter. Its notes are heard very early in the spring, uttered in a clear, melodious tone, forming a song of considerable beauty, and as a cage-bird it is a great favourite. Under good management the Chaffinch will live a long time in a state of captivity, and should be fed upon Canary, Rape, Flax, and other seeds, to which may be added a mealworm occasionally and a little fruit. The latter will tend to keep the bird in good health and the plumage bright. The nestlings of this species are not difficult to rear by hand, and prove tamer than those that are captured when full grown. In gardens the Chaffinch is very destructive during the spring in uprooting seedlings as soon as they appear above the surface of the ground, although it does much good by the destruction of numberless insects. The nest of this bird is a most beautiful structure, the external materials differing according to circumstances, so as to harmonise with the prevalent tints around it, some being covered with smooth green Lichens, while others exhibit a mixture of Moss, green, grey, and yellow Lichens, and the nests of spiders rolled up into little tufts. Various situations are chosen for the nest, it sometimes being placed on the mossy branch of an old

Apple-tree, sometimes in Ivy encircling the stem of a timber tree, but more often upon the top of a Lichen-covered protuberance, where a small bough offers a firm resting-place. The eggs are three to five in number, of a bluish-white with a tinge of pink, spotted and streaked with purplish-red. Two broods (sometimes three) are reared during the season, the young being able to leave the nest in about a fortnight. The plumage of the young birds resembles that of the hen until they moult in the autumn, and then the males obtain their handsome livery. The Chaffinch has obtained its scientific name of *Fringilla œlebs* from the fact of the sexes separating into distinct companies after the breeding season.—S. S. G.

Death of Linnet (*E. D.*).—Your bird appears to have died from excessive fatness of the internal organs, a complaint to which caged Linnets are very subject. They require much exercise, and this the small cages in which they are usually confined do not permit. In an aviary or large cage these birds enjoy the best of health and survive many years. In a confined space, however, they need very careful treatment in order to prevent them becoming over fat. In its wild state this bird feeds upon the seeds of many noxious weeds, such as Thistle, Plantain, Knotweed, Dock, and would, no doubt, thrive in captivity if these seeds could be supplied. The usual diet for caged Linnets is Canary-seed as a staple, with other seeds added in small quantities, such as Summer Rape, Maw-seed, Hemp, or Lettuce-seed. Hemp-seed should be used very sparingly, as from its oily nature it is very fattening. For green food they may have Lettuce (of which they are very fond), Groundsel, Chickweed, and the green stalks of Plantain. A little salt given now and then proves very beneficial. Coarse grit-sand and plenty of fresh water both for bathing and drinking should never be forgotten.—S. S. G.

POULTRY.

Chickens dying (*Oakbank*).—The chicken sent for examination was in very poor condition, and had evidently been improperly fed. No particulars are furnished as to food and general management. The best food for chickens after their first few meals of hard-boiled egg and breadcrumbs is a crumbly paste composed of two parts of coarse Oatmeal to one part of Barley-meal, mixed with water. When a few days old they may have grits, crushed Oats, or bruised Wheat, in addition to the paste. Also a small piece of cooked lean meat, rather underdone and minced fine, may be given daily until the chickens are about three weeks old. The use of stuffy coops is the cause of much illness among chickens, for they cannot thrive when compelled to inhale foul air for hours together, neither can they be successfully reared on a tainted, damp run, or where they have to pass their time amongst older fowls. The loss of so many broods proves there is something wrong with the ground or the management. Sometimes the failure to rear chickens arises from their having been bred from immature or unhealthy stock. Diarrhoea is often brought about through improper feeding, and in this case it is well to supply the meal in a warm state, adding a little powdered chalk and Cayenne pepper till the looseness is checked. Boiled Rice is also useful in this complaint. The coop should stand upon a good thickness of dry earth, sand, or mortar-rubbish, and the front covered at night, providing ventilation without draught.—S. S. G.

National Dahlia Society.—Arrangements are being made for the holding of a conference on the judging of Cactus Dahlias in September, 1903, on the afternoon of the first day of the annual exhibition. The conference will be opened by a paper from Mr. C. G. Wyatt. The exhibition will be held at the Drill Hall, Buckingham-gate, the arrangements being similar to those for the exhibition held recently, and the conference will take the place of the fortnightly lecture of the Royal Horticultural Society. Several new decorative classes will be added to the schedule for next year.

CORRESPONDENCE.

Questions.—Queries and answers are invited by GARDENING free of charge if correspondents follow these rules: All communications should be clearly and concisely written on one side of the paper only, and addressed to the Editor of GARDENING, 17, Furnival-street, Holborn, London, E.C. Letters on business should be sent to the PUBLISHER. The name and address of the sender are required in addition to any designation he may desire to be used in the paper. When more than one query is sent, each should be on a separate piece of paper, and not more than three queries should be sent at a time. Correspondents should bear in mind that, as GARDENING has to be sent to press some time in advance of date, queries cannot always be replied to in the issue immediately following the receipt of their communication. We do not reply to queries by post.

Naming fruit.—Readers who desire our help in naming fruit should bear in mind that several specimens in different stages of colour and size of the same kind greatly assist in its determination. We have received from several correspondents single specimens of fruit for naming, these in many cases being unripe and otherwise poor. The difference between varieties of fruit are, in many cases, so trifling that it is necessary that three specimens of each kind should be sent. We can undertake to name only four varieties at a time, and these only when the above directions are observed.

PLANTS AND FLOWERS.

Saving Petunia seed (*L. H. J.*).—When the pods of the Petunia are ripe they should be gathered and laid out on a piece of paper in a tray or box to further mature and dry. When quite ready and dry, the seeds are easily secured and cleaned, and may then be packed till required for use.

Lilium testaceum (*Flora*).—This Lily is not at all delicate, and does well in the open air, particularly if some rotten leaf-mould and peat are dug into the place intended for the bulbs and given a position where they may be left undisturbed. You had best plant it now. By *Gladiolus delicatissimus* we suppose you mean the early-flowering Blushing Bride, the bulbs of which ought to be planted during October.

Cinerarias falling (*Jim*).—The treatment of your Cinerarias seems to have been correct, and the only thing we can suggest is that the sprinkling of manure was too liberally applied. Of course, they like plenty of air, but that, according to your letter, they received. Are they kept too wet at the roots? Perhaps there may be some weevil grubs at the roots. These would be a very probable cause of failure.

Mealy-bug on Cacti (*W. H. Charlton*).—This is a terrible pest, and you will have to persevere if you wish to clear it off. You ought to forcibly spray the plants when laid on their sides with a mixture of soft-soap and ½ pint of paraffin to 3 gallons of water, applied warm. Keep the mixture well stirred to prevent the paraffin coming to the surface. The plants will require two or three dressings, and even then you will have to watch and destroy any that appear.

Roses for hedge (*Fred Coles*).—You would find the Rambler Roses, such as *Felicité-Perpetue*, *Benedicte*, *Seedling*, *Aglaia*, and *Crimson Rambler*, very suitable to form a hedge. A few lengths of wire should be run above to tie the Roses to to start them. You could also use some of Lord Penzance's Sweet Briars, which answer well for the same purpose. To give variety, you could plant *Cotoneaster Simonsi* and *Forsythia suspensa* among the Roses.

Gloriosa bulbs, storing (*J. H. B.*).—The proper way to winter these is to allow the soil in the pots to become dry, and to leave the bulbs in it all winter, standing them on a dry shelf. Or you may shake the soil out of the pots, wash the bulbs down, and place them in small pots filled with soft-wood shavings, in which they must be covered to prevent too much shrivelling. You may grow the Vines and Roses with every prospect of success. Plant *B. Hamburg* and white *Frontina*.

Storing Dahlias (*Flora*).—When the frost has blackened the leaves and the ground is fairly dry, lift the Dahlias, and when the soil falls away from the tubers they may then be stored in a clean state. Dahlias should not be kept too dry during the winter, a cellar where frost cannot reach them being an excellent place. Cover the tubers with soil, this just keeping them moist, and, at the same time, warding off frost. Here they may remain until you want to start them, say, in early March. You may divide the old tubers after they have started into growth in the spring.

Rust on Chrysanthemum-leaves (*E. Fryer*).—The leaves you send have been attacked by rust, and a remedy has yet to be found that will do good in bad cases such as yours is. We have seen several cases in bad cases, but the grower has syringed his plants with some strong insecticide, and the leaves have been thereby destroyed. It is best, therefore, as the blooms will be forming, to let them develop as best they will, and make a fresh start with clean cuttings next year. The rust is not difficult to deal with if taken in time. This can be done by picking off the leaves in early spring as the lower leaves gradually show the fungus growth.

Roses Mildred Grant and Germaine Trochon (*Rosarian*).—Mildred Grant is a splendid novelty, and we believe it will expand well in a cool-house. We have had it this year in heat, and it yielded some very handsome, clean flowers, the centre pale pink, like a Catherine Mermet, with magnificent guard petals. Germaine Trochon is an excellent Rose, worthy of a place in every garden. It is flowering just now as freely as in summer. We regard it as one of our best autumnals. The Rose makes fine long growths in the same way as *Gustave Regis*, but, like that variety, may be pruned back to about 2 feet of the base each year.

Annuals, etc., for early flowering (*Tailor*).—This is not a new idea, and, indeed, depends very materially on the locality, and soil and altitude in particular. Of true annuals it is now rather late, but a month ago many of the more strictly biennials could have been sown. You may, however, sow any of the cheaper kinds by way of experiment, as in this way you obtain

VEGETABLES.

OUTDOOR TOMATOES.

COMPLAINTS among Tomato growers are very common this year, for rarely does one hear a favourable word regarding outdoor prospects or even those grown under glass. Mr. Crook, on page 371, says Tomatoes are an absolute failure with him from non-setting, and with others in his neighbourhood the same state of things prevails. Quite recently I called on a large grower of Tomatoes near Frome, in Somersetshire, who complained loudly about the shortness of his crops. Outdoors, where he looked for a crop of some three or four tons' weight, he fears he will not have so many hundredweight. This inflicts great hardships on many, because the loss is an irreparable one, and the labour bestowed during the whole season is lost. There is, too, rent to be paid for the land occupied, and nothing wherewith to pay it. The grower under notice had just, prior to my visit, cleared off a breadth of Tomato plants which he said were absolutely without fruit, this bearing out the experience of Mr. Crook. That this is not common experience is proved in my own case, for, so far as the setting of the crop is concerned, I have nothing to complain of, but disease and the lateness in ripening make the conditions pretty equal. There remains, however, a hope that some of the fruit will mature. My plants carry, some of them, four good trusses of fruit, and present the appearance of an almost complete cordon of green fruit from the extremity to the soil; indeed, some of the bottom clusters touch the ground. I grow several varieties, and, though some are more freely fruited than others, all are fairly good. From my 400 plants a goodly quantity will be forthcoming if the weather is now favourable. It could only be expected that with Potatoes so badly stricken with disease Tomatoes should sooner or later be attacked. The wonder to me is that the plants have escaped so long and so well as they have done. Beside local selections, the varieties that have done well are Becker's XL, a really good Tomato for indoors or out; but a better, I think, will be found in Holmes' Supreme, which is fruiting splendidly outdoors, although sown and planted later than others. Duke of York, Eckford's Prolific, Early Ruby, Ham Green, and the Cropper are a few that were planted against blank spaces on the walls, and which in each instance have done well. Now what to me seems so difficult to understand is why the plants should crop so freely in one garden and so badly in others. The same cannot be said of these as of the hardy fruit crops which were subjected to the frost and chilling winds of spring. Tomatoes are so tender that they must not be put into their permanent summer quarters until frost and cold winds have gone. The weather has been unfavourable for everyone, and though summer storms are often of local origin, wet, dull weather has this year been the general rule, with but few sunny days intervening. In connection with Tomato culture it is easy to see

that though indoors the soil must be rather frequently changed, outdoors this is not so necessary, because instances can be cited where Tomatoes are grown from year to year on the same ground without any change, except the addition of a little artificial manure, which is dug into the soil at planting time. It would be interesting to learn from other readers how outdoor Tomatoes have done. W. S. Teasdale.

KIDNEY BEANS.

THE council of the Royal Horticultural Society have resolved to conduct a trial of all descriptions of Kidney or tender Summer Beans in their gardens at Chiswick next year. It is hardly probable that anything remarkably new may be found, as the seed trade are so very keen to pick up anything that is novel or has special merit. Still, it may furnish a good opportunity for any having little known varieties to have them thus publicly tried. Kidney Beans include not only very many of the dwarf or compact branching section, of which some seem to differ only in the colours or markings of the ripe seed, but they also include several distinct forms of Runners, such as the well-known Scarlet and White flowered Runner, the old long, bent podded Case-knife section, the newer climbing breaks of Canadian Wonder, known as Tondor and Truo, etc., and not least, though perhaps more seldom grown, the Golden Butter Beans, which produce bright yellow round fleshy pods and are so very nice when gathered young, cooked whole, and served with gravy. It is interesting to learn that in Scotland Dwarf Beans only are cultivated and Runners are not. Here, in the south, the Scarlet Runner types are esteemed as of the very highest value and excellence, and, coming after Peas, are the most productive and constant bearers of any garden crops. It has been this season, when cold springs started all tender Beans so late into growth, a matter for congratulation that we have had no serious frosts in September, and so far our Beans have been spared for a few weeks longer. It is rare, however, that they remain unharmed after about the 20th of October, as, being tall and fully exposed, it is not possible to protect the plants. But where in June a sowing can be made close to a south wall or fence and the plants got into fruit in the autumn, then, by means of double or treble netting or mats hung over the plants at night, it is often possible to save them for some few weeks longer and thus render a great service. A very useful trial of Dwarf Beans in pots forced might also take place, but the utilisation of them in that way is very limited, whereas they are universally grown outdoors. But where there is a vinery, Peach or orchard house where there may be room for a few boxes 2 feet long and 8 inches wide and deep, if some dozen of seeds of the Climbing Canadian Wonder be sown in each one, and in due course sticks as supports added, then very early and most useful crops are obtained at little trouble or cost. Generally tender Beans are sown too thickly. The leading growers

who produce such fine examples for exhibition do not make that mistake, and as a result not only do they get great crops, but also very fine long, straight pods. In sowing Runners it is a good plan to have double rows, 9 inches apart, and the Beans in each row fully 9 inches apart also. Dwarf Beans, because of their hushy habits, want even more room for strong growers like Canadian Wonder, but weak growers will do well closer. A. H.

It would be very interesting to compare the notes on the trial of Kidney Beans made over twenty years ago with those on the above trial, and also, if possible, compare the dried seeds, which at that time were split in half, pasted on to a thin board covered with white paper, and enclosed in a glass case. If we remember rightly, attention was also given to the colours of the flowers.—E. J.

NOTES AND REPLIES.

Radishes in autumn.—Some may say these are not wanted in autumn. My answer is they are in many places, and would be appreciated more were they sent to the breakfast-table. I am aware the greatest demand is in the spring, when they are young and tender, many giving them up when the warm weather comes from their being strong and tough. When sown in autumn they are equally as tender as in the spring, and make a nice change after Cucumbers and other salads have had a turn. In country houses where shooting parties are, Radishes have an extra value, and are nice to mix in the salad-bowl. I grow some every year, sowing with Autumn Spinach and Onions, throwing the seed broadcast after the drills are filled in, and raking it in. In this way it is but little trouble, giving a long supply.—J. Crook.

Carrots cracking.—I grow a large quantity of Carrots for the house, but a great proportion of the sorts is apt to split. I enclose some extreme specimens. Wireworm has been very troublesome this year. Has this anything to do with the sorts splitting? The soil is deep and good, and is copiously dressed with lime, which is deficient, and the Carrots are sown in drills with root and wood-ashes. Can you suggest any prevention by cultivation or otherwise for this almost total destruction of the crop by splitting?—IGNACIUS.

The cracking of Carrots is not uncommon, especially in early sowings. The cause is usually a stoppage of swelling in dry weather, then renewed moisture causes rapid swelling of the roots, which very often burst in the process. Wireworm has nothing to do with the splitting, but these pests often bore holes in them, and also often eat the roots clean through when small. Perhaps you sow too early. The best plan in your case would be, if you want good eating Carrots, to sow in shallow drills, 8 inches apart, on a south border early in March, Early Short Horn, to pull when quite small. Also make a small sowing early in April on a warm border, in rows 10 inches apart, of Early Nantes, thinning those down to 2 inches apart in the rows later. Then make a sowing of Intermediate towards the end of May for winter use. If you make yet a further sowing about the middle of July thinly, and not to be thinned later, you will have a good supply of Carrots.

FRUIT.

FIGS AND THEIR CULTURE.

It is doubtful if there is a more wholesome or delicious fruit cultivated than the Fig, provided the fruit is well grown and fully ripe. Figs are by no means difficult to grow either under glass or on open south walls, but all alike do not meet with success. What Figs require and must have is plenty of light and heat, a very firm and not over-rich root-run being also most desirable. For a few years they are fairly productive against back walls of lean to houses, but in time the fruits are produced on the uppermost branches only, and in small numbers there. If the same trees were gradually trained a few feet down the roof more fruit would be forthcoming than ever before, and this might well be done in many cases where the back walls only have hitherto been devoted to the trees. The plan of growing large bushes in the body of the house, the back wall also being covered, answers fairly well, but in the long run it will be found much the better plan to be content with two or three trees, no matter how large the house, and to train these up the roof only. Thus treated the growth is usually short jointed and exceptionally fruitful (see illustration), the Figs being also large and of superior quality. This plan of training is suitable even for quite small forcing-houses, the trees in this case having their roots confined to narrow borders, and well fed when in full bearing. It is not in houses where high temperatures are maintained, or such, say, as would suit Melons well, that the trees are apt to form soft unfruitful wood, but rather in unheated structures. Thin training, though desirable in all cases, is absolutely necessary in unheated houses. A judicious selection of varieties, of which there are many, is also of great importance. The old Brown Turkey would, however, yet appear to be the best of the lot. So good in every way is this popular variety, that there is little or no need to plant any other sorts—under glass, at any rate. It is the surest bearer under all circumstances; it forces readily and succeeds well in or out of pots, while the fruit is always of superior quality. The second, and, in some instances, third crop, though frequently so small as to be quite unrecognisable, is particularly delicious, many people who were previously under the

westwards, these, perhaps, being the hottest corners in the garden. But if these are the best, it does not follow that they are the only positions where Figs will succeed, though it is next to useless to plant them against any other than south walls, and the higher the walls or the more head room that can be

PRUNING should be delayed till the young fruit shows at the points, or say late in April, and then should chiefly consist in thinning out, long naked branches being cut back to near the centre of the trees, or else foreshortened to a well-placed younger fruiting-branch. Thus treated the trees are kept furnished with

A valuable late Fig—Nebian.

allowed the better. That Figs are occasionally to be seen doing well against walls with a south-west aspect is readily admitted, but as a rule the wood fails to ripen well in such positions, a moderately severe frost being liable to cut it down to the ground. Once a tree has of necessity to start afresh from near the stems, it is usually several years before it again attains a productive state, nothing but long sappy shoots being formed; hence the great necessity for protecting the points especially of the branches every winter, the trees being unloosed from the wall for that purpose. Allowing the trees to have their head somewhat is a certain way of checking grossness, the wood made then being principally short-

young fruiting-branches throughout their surface, and not at the ends only, as too often happens.

Soil.—Not a little depends upon the preparation of the borders. Rank growth being most undesirable, a rich, loose root-run ought not to be provided. Only a limited number of readers are in a position to use much chalk or chalky soil in their preparation of a border, but if it can be had it might well be mixed with fresh turfy loam, one part of it to two parts of the loam, a sprinkling of half-inch bones being the only other addition. An excellent substitute for chalk will be found in old mortar rubbish. Comparatively small borders answer well in any case, these being well drained, and, if a clay subsoil abounds, the bottom ought to be concreted to a considerable distance around in order to keep the roots out of it. It is also advisable to make the borders very firm, and if there is a path or roadway in front of the outside trees, these have a good effect on them, checking grossness and promoting productiveness. The number of trustworthy

VARIETIES FOR OPEN-AIR CULTURE is very small. Foremost amongst these must be placed our old favourite Brown Turkey, this being the sort most generally grown, and it cannot be improved upon. Brunswick is also a hardy variety, but not nearly so fruitful as the Brown Turkey, while the White Marseilles is perhaps the most delicious variety of all. The tree is hardy, very productive, and the fruit small, but when well ripened the fruit can be eaten by most people.

FIGS FAILING.

COULD you kindly advise me what to do to make my Fig-trees ripen the fruit? I have three Fig-trees in the garden (one against a south wall and two as standards). They all bear quantities of small Figs, which never open and do not grow larger than Walnuts. I have removed the soil round the trees to the depth of 2 feet and a diameter of 4 feet, and have filled in with old mortar, brick bats, and building refuse. This I did two years ago, but cannot see any improvement. Will you tell me whether I ought to cut back the growth, as the trees grow so much to wood?—E. E. BUCK.

I have a Fig-tree growing against a south wall, but overshadowed somewhat by a large Maple. It bears very scantily. Should the old wood be cut away, or what treatment can be advised?—A. E.

[The fact that the trees make strong growth is plain proof that the steps taken two years ago were not sufficiently drastic to correct the evil and bring them more under control. The removal of the soil round the trees to a depth of 2 feet, and at a diameter of 4 feet from their stems, was a step in the right direction; but you should have gone further, and have tunnelled right under the "balls" of each, when

Fig Violette Sepor.

impression they could not eat Figs eating these readily.

CULTURE.—Along the south coast, notably where a chalky soil abounds, Figs succeed fairly well as standards. The proper position for Fig-trees is the angles formed by the junction of a south wall with a wall being

jointed, hard, fruitful, and not so easily crippled by frosts. The safest and best practice, therefore, with wall trees is to keep them freely thinned out, regularly trained, no attempt being made to confine them to a limited area, and to further protect them with Fir branches, or straw thatch. The

you would have met with one or more strong roots descending to the subsoil. These should be ruthlessly cut away close up to the ball, because so long as these roots exist the trees will continue to make quantities of strong wood, and, if they bear at all, the fruit will never come to perfection. Your best course will be to reopen the trench at from 3 feet to 4 feet from the stem as soon as the trees shed their foliage. This trench should be 1 foot in width, to admit of the work being done conveniently and expeditiously, and be carried to a depth of from 2 feet to 3 feet, so that the soil can be cut away from under the base of the ball, tunnelling under one half of the ball at a time so that there shall be no accident. In the digging of the trench cut all roots found clean away, and when the one half of the ball has been exposed in the manner described, fill in with brickbats and mortar-rubble, placing this in layers and ramming it as firmly as possible to get it. The brick-rubble, being of a dry nature and possessing no manurial constituent, will have a direct tendency to check exuberant root growth in future, and being, moreover, 1 foot in thickness, any roots that may penetrate will be of a fibrous nature only for some time to come. The best way, of course, in dealing with Fig-trees is to enclose their roots in a kind of brick tank, 3 feet to 4 feet square, concreting the bottom and building the sides with bricks laid in cement, and making provision for the outlet of water at one corner into a rubble drain.

If the above work is carried out early this winter you may leave the pruning until the spring, when the growths on the wall-trained tree may be thinned out, cutting away all the weakest and retaining those well furnished with embryo fruits, which will be plainly visible at that date. Just sufficient wood should be laid in to furnish the wall, and no more. With regard to the standards, the heads should be somewhat thinned out, or sufficiently so that sunlight and air—two important factors—can reach to all parts. Should next season prove a dry one, pay particular attention to root watering, and when the fruits are swelling towards maturity give liquid manure weekly; or, failing this, dissolve 2 oz. of Peruvian guano in each gallon of water required. Some trees that we treated thus last autumn have been yielding heavy crops of fine fruit for some time past.]

FRUITING AND NON-FRUITING FIG-TREES.

The theory which I placed before you a few weeks ago as to some Fig-trees being fruitful and others not, and to which you replied in your paper of September 20th, page 383, was intended to open up replies and experiences from Fig-growers, and to raise interest in the matter generally. I am quite aware that my

Fig Bordeaux.

views are not those held by most growers. They are briefly these, that (1) there are Fig-trees which never bear any fruit: these I call males. (2) Fig-trees bearing fruit which drop off even in mild weather: these I call females. (3) Where these two kinds are grown close together, either accidentally or intentionally, the fruit on No. 2 will not fall off, but come to maturity and ripen. There seems to have

been a difficulty from time immemorial in inducing certain Fig-trees to fruit. May not my solution of the mystery perhaps be the right one? I do not find Figs want rich soil or manure. Plenty of rain-water is all they require.

In reference to your note on this subject in GARDENING ILLUSTRATED of September 20th, I

Fruiting-branch of a Fig.

have probably more than 100 trees of different sizes, some out-of-doors and some in a cold-house, and all are confined as to root-space. They are in 10-inch and 12-inch pots, lard buckets, etc., so that I can move them from place to place at pleasure. None have been raised from seed; most have been taken from suckers from my own and my neighbours' Fig-trees. I think I have only two, or at the most three, kinds of Figs. I am sending you four leaves taken from four separate trees; two of these are non-fruited, which I, in my ignorance, call males, and the other two I call females; these bear and ripen the fruit now that the non-fruited (male) trees are placed close to them. You will notice a decided difference in my so-called male and female leaves. H. N. G.

Both.

NOTES AND REPLIES.

Planting Filberts.—Will you please tell me if I may plant some Filberts now or keep them until the spring, as I wish to grow some? How long would they be before they bear?—W. W. JENKIN.

[Plant your Filberts during November, allowing 10 feet between the rows. Spur-pruning is the best for the branches, and when the trees have been well attended to for several years, the spurs become numerous and fruitful. The form which suits the trees best is the basin shape usually applied to Red Currant-bushes. All will depend on the growth and attention given to pruning, manuring, etc., as to when they come into bearing.]

Earwigs eating Nectarines.—Can you suggest anything that will be effectual for the protection of wall fruit from garden pests? I have a garden this year for the first time, and had a very good crop of Nectarines, Apricots, and Peaches, but as soon as the Nectarines began to ripen they were attacked by some enemy, which went over and ate the fruit half round between dusk and dawn, and afterwards they were quickly eaten up by troops of black ants, wasps, etc., so up to the present I have had no opportunity of sampling them myself. The Apricots also suffered, but in a less degree, but in the case of these nearly all cracked, and the juices exuding soon attracted ants, spiders, and that interesting little insect which makes a ball of itself when surprised, so these, too, proved a failure. I have a fine crop of Peaches, but these are not sufficiently ripe yet to receive much attention. Can you give me a little advice in this matter of protection, also do you know anything to prevent the cracking of Apricots.—A. V. A. T. R. T.

[The enemy that destroys your fruit is the earwigs. The only way of destroying them is by trapping them, or, as they are night feeders, catching them when dark. The best traps are the hollow stems of Sunflowers or Broad Beans, from which the earwigs may be blown into a basin of boiling water or water on which a little paraffin floats. Small garden pots filled with dry Moss or hay are useful; in fact, anything in which the earwigs can hide during the day.]

Fruit-trees on an Oak fence (H. K.).—With respect to the planting of fruit-trees, cordon or otherwise, trained against a split Oak fence, much may depend, first, on whether

the palings are on the garden face or the rails are, and, second, whether behind there is any shelter from cold draughts. A fence of this description properly made should allow of but very little draught, but if the palings are old and have become shrunken, then much cold air will rush between the cracks, and be very harmful. If you could in any way fill the spaces between the rails with what is called matchboarding you would render the fence airtight. If the posts and rails be inside you would have to strain stout wire along the faces of the posts, 9 inches apart, to which to tie the trees. If the face of the palings be on the garden side you could nail the trees to them. Were a Privet hedge planted behind the fence, a yard from it, and kept hard trimmed, that would exclude draughts, but it may not be practicable. Walls are better than wood fences, because they are impervious to draughts and retain much sun heat.

Jargonelle Pear failing to fruit.—In my garden there is a large and old Jargonelle Pear-tree, the lower part of which is in a fowl-house—that is to say, the lower part is built round it, space being limited. Formerly I had splendid crops of Pears, but for some few years now I have had very few, and these have been maggoty. This year the crop was much larger again, but many of the Pears were small, and quite two-thirds contained maggots. Nothing has been done to the tree or its roots for many years. Can you suggest a course of action? Would lime-washing the trunk do any good as regards the maggots?—C. F.

[It is not a matter for surprise that the large old Jargonelle Pear-tree in your garden does not now produce good fruit, seeing that you have built a fowl-house round the stem. Of necessity, that house must cover a good deal of the ground in which the roots are, and would therefore keep that portion very dry. Again, by thus covering up the stem and ground you keep it in shade, whereas ample sunlight is essential to health. We fear there will be no improvement in your Pear crop until you remove the fowl-house. Even then it would be desirable to open a trench all round the tree, 6 feet from the stem, 2 feet wide, and as deep, cutting off any large roots, and, if possible, any that strike down under the tree, then refilling the trench. Fork in over the roots a dressing of manure, and thoroughly coat the tree and branches with hot lime-white, in which a little clay is mixed to colour it. Also syringe the top branches with the lime white.]

Watering Fig-trees (Fendho).—Usually, Fig-trees on walls outside grow too luxuriantly and make too strong growth. That results from the fact that roots have gone wide afield far removed from immediate waterings. In such case they would benefit

Fig Brown Turkey.

only when heavy rains fell. When it is needful to severely root-prune trees to induce them to form less wood and leafage and produce fruit, occasional heavy waterings, close home, and top-dressings or mulchings of manure are essential. Figs in pots need very liberal watering, certainly in warm weather once a

day, and sometimes twice daily. They should have liquid-manure three times a week; also, the trees be often syringed, and the floor kept well moistened. All this is needful, because the roots are much cramped. Outside too often they have far too much room, and an occasional hard root-pruning helps to throw the trees into bearing.

Planting fruit-trees.—I have a longish length, nearly 200 feet, of Oak fence facing S.W. It is about 6 feet 6 inches high, and about half of the border in front (8 feet or 9 feet wide) is used for flowering shrubs and perennials, and the other half for vegetables. Soil, light subsoil, sand, and gravel. This year, thanks to the rain, the plants of all kinds have grown well, but it is usually very dry and bare. Will you kindly tell me (1) what Roses would do best on the fence, and (2) what kinds of wall fruit, say espaliers or cordons? I have also a smaller length of a similar fence facing N.E. What wall fruit would do on that? I have a Victoria Plum which does fairly well, and a Williams' Pear which has never fruited. —W. J. W.

[To get a break from the railway close to your garden plant Lombardy Poplars. These, planted 8 feet apart, soon make a close screen and give shade. But if you mostly want flower and fruit, you had better plant strong

PLANTS AND FLOWERS.

OUTDOOR PLANTS.

CAPE MARIGOLD (DIMORPHOTHECA).

THIS genus, belonging to the Compositae, comes from the Cape. In

D. PLEUVIALIS the flowers are white and purplish beneath, opening freely in fine weather. Plants from spring-sown seed flower from July to September. It is a bold, free-growing annual, thriving in any good soil, and an effective ground plant with the larger flower garden subjects. It is, however, well worth growing alone.

D. ECKLONI.—This is a beautiful and interesting plant of shrubby, perennial habit, with Marguerite-like blossoms, as may be seen from our illustration. It is of somewhat rather curious combination, the fleshy leaves and stems resembling those of the larger forms of the Candytuft family, while the large white and blue suffused blooms are also very distinct.

Dimorphotheca Eckloni. From a photograph sent by Mr. J. Rose, Oxford.

standard Blenheim Pippin Apples or Siberian Crabs, though the latter fruits are useless. Farleigh Prolific Damsons would do very well and fruit freely. We should not advise you to plant both Roses and trained fruit-trees on your Oak fence. Where there are no flowers, there plant fruit-trees, such as Green Gage, Rivers' Early, Victoria, and Monarch Plums, and Louise Bonne and Marie Louise Pears. We should prefer horizontal trained or fan-shaped trees to cordons. Such Roses as Crimson Rambler, Carmine Pillar, Alistar Stella Gray, W. Allen Richardson, and Gloire de Dijon would do well if planted. Victoria Plum, Catillac Pear, and Morello Cherries are the best fruits for a north-east aspect. It is not warm enough for a Williams' Bon Chrétien Pear.]

Request to readers of "Gardening."—Readers, both amateur and in the trade, will kindly remember that we are always very glad to see interesting specimens of plants or flowers to illustrate, if they will kindly send them to our office in as good a state as possible.

The deep blue disc is a very interesting feature, and here and there, as golden anthers protrude, it is quite exceptional. The plant is easily raised from seed, which is best done every year, as two-year-old plants are liable to become leggy. It is a beautiful plant when the ray florets respond to the warm influence of the sun's rays, but dull, sunless surroundings are not at all suited to show it at its best.

HYBRID JAPAN ANEMONES.

GARDENS in the autumn will be better and brighter for the new forms of *Anemone japonica*. We cannot have too many of those bardy flowers that yield us the full measure of their beauty when early autumn frosts or drenching rains have destroyed the effectiveness of tender bedding plants. In a general way the first flowers of the Japan Anemone open at the close of August, the display lasting up to the end of October; indeed, one may in mild autumns gather good blooms in the middle of November. After many years of sterility the white form produced seeds in an Irish garden.

From these, two varieties differing somewhat from the parent plant were raised and distributed under the name of Lord and Lady Ardillan. My experience of them is that the former is an excellent free-growing, reliable kind, but the latter is constitutionally weak and will only do well in very good soils. In periods of severe drought the leaves become discoloured, the energies of the plants become so paralysed that the flower stems cannot develop properly. Lord Ardillan, on the contrary, is in every way good and reliable, the half-opened flowers being in form much like partially-expanded blooms of the white Water Lily. Previous to the introduction of these varieties there came to us from America a variety named Whirlwind. There is no record as to the origin of this kind, but as it is quite sterile I am of opinion that it is simply a sport from the type. When I first grew this variety I was not at all impressed with its worth. I grew it generously, and with the result that it made a very strong coarse growth, the leafy bracts at the base of the bloom developing to such an extent as to almost destroy the effectiveness of the plants. It was only by chance that I discovered the true worth of this variety. I happened to lay some plants into very poor light soil. They were forgotten until it was too late to set them out. They made quite a different display from those in rich soil, the flowers being produced in great profusion, very pure and not disfigured by leafy growths. For cut bloom I value this variety very much, the pure finely-formed blooms being especially valuable for wreath and cross making. They last longer than those of the type, and have a chaste appearance in floral decorations. *Rosea superba* has no resemblance to the old rosea, which is a tall growing kind with no pretensions to effectiveness. It has very large, finely-formed blooms, produced in great profusion on stems about 3 feet high. The petals are delicately flushed with rose, the effect in the case of established specimens being remarkably fine. I find that it increases rapidly, so that in the case of a permanent plantation the plants should be set out 3 feet apart. It is a curious fact that this variety was raised by M. Lemoine, of Nancy, and in England at about the same time. From the first head of seed I ever saved I raised one plant only. I bloomed it indoors, and had a poor opinion of its merits. The following year, in the open ground, it showed its true character. It was fortunate that I did not name and distribute it, for later on I found it to be almost, if not quite, identical with Lemoine's variety. *Beauté parfaite* will, I believe, be largely grown. It is the finest of the singles, the flowers being very large, produced in great profusion. It is free of growth, and will undoubtedly be a favourite with trade growers and others who require a good supply of pure white flowers at a time so many things in the outdoor garden are over and *Chrysanthemums* are comparatively scarce.

The flowers of *Coupe d'Argent* are composed of several rows of petals; when first expanded they are creamy white, but become pure white with age. It is free-flowering, has a good constitution, and should certainly find a place in gardens where this kind of hardy flower is valued. *Collerette*, *Vase d'Argent*, and *Couronne Virginale* may be said to be glorified forms of Whirlwind. They are all more or less double, and very pure in colour, the finest of them, in my opinion, being *Vase d'Argent*, which has flowers of great substance, composed of about six rows of petals, regularly arranged and fine in form and colour. This variety is of very strong, sturdy growth, the flower stems, in my experience, being more robust than those of any other member of the family. *Collerette* is much in the way of the last-named, the petals being regularly disposed and the flowers finely formed. These double kinds I have found very serviceable when grown in pots. They bloom rather later than the single kinds, so that one can have plenty of perfect flowers, very pure and fine, all through October, and frequently up to the middle of November. Well grown, these Japan Anemones have a fine appearance in 8-inch pots, and may be made good use of in conservatory decoration. They harmonise with scarlet Geraniums, *Vallotas*, *Lilies*, etc.

Original from

Queen of Wurtemberg, a semi-double pink variety, is distinct and well worth growing; it does not, however, appear to be quite so vigorous as the white kinds. Mont Rosa, with double pink flowers, is a great advance among coloured kinds, and indicates what we may expect in the future. In time we shall probably get varieties as double as the Rose and more highly coloured than those we now possess. I should not be surprised if we get right shades of red, deep crimson, and other intermediate tints.
J. C.
Byfleet.

OLD TREE PÆONY.

It will probably take many years to persuade gardeners not to arrange everything they plant like dumplings. Their ideal is to make everything as snug as possible, in that way defeating their own object if they seek variety, or pace, or any of the things that go to make a picture.

Putting the tall things in the middle and bringing down the plants to the margin, and

two plants which had been given me) at the top of my rockery, exposed to all the sun we could get, but sheltered from north and east winds. They have grown well and bloomed freely. My flowers are all a clear white on the upper surface, with a pale lilac under surface. They shut up if a shower comes, and hang their heads, but as soon as the sun shines on them they turn up their blossoms and open again. If "A. W." will try it in the rock garden, I think he will like it better.—A. C. RIVERHEAD.

Omphalodes linifolia.—Readers of GARDENING wishing to grow the pretty Forget-me-not-like flowering annual, *Omphalodes linifolia* (p. 397), can find it in some lists as *Venus Navelwort*.—D. W.

Nicotiana affinis.—I have no greenhouse, and am anxious to have a bed of *Nicotiana affinis* next summer. I put some roots in the ground this spring, and they are doing wonderfully well and growing all over my flower-border. Could I lift these, say, in November, and put them all in the bed and cover with litter, or what do you advise?—HILLY.

If you cover up the roots of the *Nicotiana* with coal-ashes, Cocoa-nut-fibre, or leaves, the roots will survive, and, when starting into

and evenly, so as to make a perfect edge. Put back the soil against it, tread firmly, and then replace the gravel. Each summer you ought to cut it back to its original height or thereabouts, but, of course, allowing it to become a little broader each year.]

Renovating a lawn.—I have a piece of lawn which grows nothing but rank Grass and Dandelions. I am having it all dug up and trenched and the bottom broken, placing the top spit of turf at the bottom. The subsoil is gravel and sand, and at the end of the garden is a railway cutting which tends to increase the dryness of the garden generally. I thought of digging in some cow-manure during the winter and re-sowing in March. Will you kindly tell me (1) whether it would be preferable to use artificial manure, such as basic-slag, instead of the cow-manure, or should I use both? (2) Whether Clover would be likely to make a closer and more lasting lawn in such a dry spot than the ordinary lawn Grass, and if so, what kind I should obtain?—W. J. W.

[You are evidently taking the only useful course in relation to your weedy lawn in thoroughly forking up and burying the weedy surface and replacing it with fresh soil from beneath. We hope you will not find that full of weed seeds later; but weedy lawns usually are the product of foul soil, and not of weol

Old Tree Pæony at Glynde.

If the little bag of tricks they use, only lead to a bad end. Happily, some things do not end themselves to this treatment, and so we do see occasionally a shrub in a garden that shows some form or natural grace. Among these there is nothing, perhaps, more striking than an old Tree Pæony, and this illustration shows one at Glynde, in Sussex, a very fine old plant, which, breaking away from the set shape, with its branches above the general level, formed a striking picture when in flower. We should encourage more and more things that have this free habit, and never seek to repress it.

NOTES AND REPLIES.

Arctotis grandis.—"A. W." asks for the experience of others who have grown this plant. My experience differs from that of "A. W.," as I am very pleased with it. Owing to the severe weather we had in May, I did not put mine out till June, when I put them (only

growth next spring, may be lifted, divided, and put into whatever positions you wish. You ought to lift the *Sileno* at once and plant it in the flower beds.]

Box edging.—"Please advise me as to a Box border? I have some beds edged with Box, but it is in places very ragged and dead. The Sweet Violets, too—growing like weeds—have pushed up in great bunches in the Box. What measures should I take to make it flourish? In many places it is thick and strong.—Mrs. WALTON.

[The only thing you can do is to relay the Box, which you may do at once or leave till the spring. It often happens that Box is neglected and not kept hard clipped, the result being that it gets tall and ragged, as in your case. First draw back from the edge all the top gravel some 12 inches wide, then lift the Box and take it away, laying it in by the roots. Then fork up the ground where it grew, adding some fresh soil and some manure. Strain a line, chop down a straight furrow 6 inches deep, have the Box hard trimmed, tops and roots, to about 7 inches, then plant it thinly

seeds being in the pasture seed sown. Certainly add cow-manure in preference to basic slag, as the soil is no doubt poor, and cow-manure will both enrich it and render it the more solid. The close-growing Clover has been excellent on lawns this season, because so damp; but it may not be so another summer on poor, sandy soil if the season be a dry one. Your best course will be to ask some high-class seedsman to send you Grass seed, stating nature of soil, area of lawn to be sown, purpose for which needed, etc. When the ground has been manured and dug, tread and level it well before you sow the seed. Do that early in April, and keep off birds.]

Blue flowers for spring.—Two of the most cheerful of our early spring blossoms are to be found in *Scilla sibirica* and *S. bifolia*, the latter being a very bright blue, and blooming early, *Chionodoxa*, also, *Lucilia* and *sardensis*, the former being the white-centred Glory of the Snow, and *sardensis* having deep blue

flowers. All bloom early in the year and all are inexpensive; they form a nice setting to beds of Tulips and Hyacinths, which otherwise would be devoid of colour for a time, or for edgings to walks mixed with Crocuses. Like Crocuses, etc., when once planted Scillas and Chionodoxas may be left alone for years, and each season in the early months they will bloom freely. Plant now.—W. F.

Utilising shady bed.—At the foot of my garden I have a bed about 45 feet long by 3 feet wide overhung by trees. It faces west, and is backed by iron railings, with a drop of about 1 foot on the side remote from me. Could you tell me any flowers which would grow there, or what would be the best way to utilise it? I thought of making a rockery and planting Ferns, etc. If so, what would be the best kind of Ferns to use?—E. BERRY.

[If the roots from the trees are not too near or numerous, you may with advantage grow Lily of the Valley, Solomon's Seal, Christmas Roses, Hepaticas, London Pride, and such flowering plants quite well; indeed, the position should exactly suit the Christmas Roses if the soil is good or can be enriched by manuring. You could also plant such bulbs as Muscaria conicum, Fritillaria Meleagris, F. imperialis, the double white Poet's Narcissus, Tritoleias, Scillas, Wood Anemones, and other things, or possibly a mixture of hardy Ferns with the above named would be most interesting. Any of the more plentiful of the Ferns would do quite well—for example, Athyriums, Scolopendriums, Lastreas in many kinds, and Polypodiums. You would also require some old root stumps from trees, or rough stones arranged here and there, and, by placing these first in position, the gaps may be the more readily filled in with plants. Of course, the simpler way would be the flowering things first named, and, as these are among the better class things, you may probably embrace this view. If you wish to quickly hide the soil, we can recommend the London Pride and some of the bold-leaved Megaseas (*M. ligulata purpurea*), which is also a handsome flowering plant. In adopting this method it will be easy to reduce the London Pride at any time when it is required. The flowering plants and bulbs mentioned would give quite a lengthened display of bloom. If planted in mixture, the tree stumps will hardly be required. But whatever you plant, you should thoroughly dig and manure the bed previously.]

INDOOR PLANTS.

MOVING VIOLETS TO THEIR WINTER QUARTERS.

THE latter end of September is a good time to move Violets to their winter quarters, and if the plants have been well treated during the summer, the small single crowns will have developed into fine clumps bristling with flowers and flower-buds. I am not particular as to the quality of the soil in which to put them at this stage, provided it is light and congenial to healthy root-action. The accommodation I have for wintering Violets is ranges of sunk pits with concrete walls a few inches above the ground level. Such pits are easily protected from frost, and wind has not such power on the lights—a consideration in exposed gardens. In these pits the plants are placed rather thickly with the leaves almost touching the glass. As planting proceeds they are well watered, thus settling the soil around the roots as well as washing the dirt and grit off the leaves. Unless the weather is unpropitious or very wet, they are fully exposed for a fortnight, or as long as no danger from frost is imminent. By this exposure no trouble ensues from leaf-damping, which, as all are aware, is a serious check to the free and perfect development of bloom. Excepting during severe weather I allow a current of air to play over the plants day and night, but protect thoroughly with Bracken and mats from being frozen. When necessary (which is not often during the dull and short days) water is given, choosing a dry morning to enable the foliage to dry by nightfall. As regards watering, I would specially caution novices in Violet growing to beware of giving their plants liquid-manure while in bloom, for the flowers retain its unpleasant odour for a considerable length of time. Should the plants or blooms require stimulating, better by far give them a tonic in the shape of a top-dressing, washing well in

with clear water. I find it beneficial, especially during the short days, to slightly syringe the plants overhead about mid-day with tepid water, closing the lights for an hour after; thus assisting the blooms to develop.

The foregoing remarks apply chiefly to the double varieties and weaker kinds, but the cultivation of the single and stronger sorts differs only in degree, such as more space being allowed between the plants and not treating them to quite so rich a larder. Neither is it necessary at all times to winter these latter under glass, unless it is especially desired to forward the blooms. In the cultivation of Violets the following points are very important: Select an open position, light and air being necessary to ripen and plump up the crowns; cultivate well and treat liberally, mulching freely early in June; feed liberally, but wisely, water periodically, and keep clear of runners and weeds; avoid watering with liquid-manure during the winter, apply no heat, and ventilate freely on all favourable occasions. R.

—October is the month, early or late, according to locality, to get under glass Violets that have been grown for the purpose. There can be no doubt unheated brick pits are the best to grow the plants in during winter, Violets disliking fire-heat in any form. Assuming these pits have been occupied with Melons or Cucumbers, the crop will have become exhausted quite early in the month, and all that will be necessary to do now is to get out the soil, and then refill with old hotbed-manure or stacked leaves to within 12 inches or 15 inches of the top of the frame-work, treading it well before putting in the soil, which should be fairly light loam with the addition of a little leaf-mould and wood-ashes or soot, mixing well together. Lift the plants carefully with the spade, retaining good balls of soil, cutting away all runners, and plant 4 inches to 6 inches apart, making the soil quite firm around the roots, and if the soil should be on the dry side, give the whole a thorough good watering with rose cans. It will not be necessary to put on the lights for a few weeks, when by that time the soil and plants will have sunk down enough. During open weather the lights should be drawn back entirely, as Violets enjoy plenty of fresh air; in fact, if you begin to coddle them they soon resent it, and unless it is very wet or the nights frosty, plenty of ventilation should be afforded them. Towards the end of November mulch the surface between the plants with Cocoa-nut-fibre refuse. This will keep the bed moist for a very long time, though, on the other hand, the plants must not suffer from the want of water at any time. Should the leaves suffer from the "spot" disease, dust with flowers of sulphur immediately. J. M. B.

NOTES AND REPLIES.

Brugmansias.—*Brugmansias* are beautiful when in flower, and when seen as centres to beds are attractive. It is time they should receive the shelter of the house or some place where frost cannot reach them, such, for instance, as a potting-shed or outhouse. Where room can be found for them in the greenhouse it often follows that they bloom fairly well on being introduced to heat.—TOWNHALL.

Epicacris.—Among the most valuable of our hard-wooded plants for conservatory and table-decoration are the *Epicacris*, and by varying the treatment one may have them in bloom from November to April. By this time plants which have been standing out-of-doors or in cold-frames will have been removed to the house, and ere long some of the earliest buds will show colour. Dryness is fatal to them at any time, particularly so just now.—DERRY.

Dentzia gracilis.—Will you kindly inform me what is the best treatment for *Dentzia*? I have some in large pots. They have been outside all summer. I want them in flower early. What had I better do with them now? What is the best position for them? Information will greatly oblige.—ROSLAY SWIN.

[We suppose that your *Dentzias* have been standing in the open air since they flowered last spring. After flowering they ought to have been gradually hardened off, and when all danger from frost was over stood in the open air. Any old and exhausted wood should also have been cut out, in order to allow the young shoots to develop, while, if necessary, the plants should have been potted. You must now plunge them in ashes in the open air, where they will be quite safe until you wish to introduce them to heat early in the coming year.]

Staphylea colchica for forcing.

This is one of the best of our hardy shrubs for forcing for early spring, and where white flowers are wanted arrangements should be made for potting a few plants, keeping them in a house or frame away from frost until within a few weeks of the time one needs them in bloom. It will stand forcing, but it must be gentle, therefore it is desirable to get plants into cool quarters as soon as possible. *Staphylea colchica* should never be allowed to become too dry, and occasional syringing of the plants with tepid water will keep them clean, as well as assist development of buds.—LEADHURST.

Potting Canterbury Bells.—Not requiring much heat to get them into bloom early, one would have thought that these slow plants of our borders would have received more attention as pot plants, but for trouble about them, and one often finds that early-flowering plants in houses are largely made up of expensive subjects. To those who do not object to the trouble of potting up a few now let me commend the Canterbury Bells. They should be placed in cold-frames, ventilated freely, and brought into gentle heat early in the new year. One may have a brilliant show under glass with these at a trifling cost.—WOODRUSTWICK.

Fuchsias.—Will you kindly inform me how I should treat my Fuchsias, which at present are covered with flowers? 1. Should I take cuttings from them now, or when? 2. How should I treat the cuttings? 3. Should I treat the old plants, (a) those in pots and (b) those in beds, observing that, if it can be done without any detriment to these Fuchsias, I wish to remove them to the bed. Christmas is near, and I wish to get the plants in the beds. Can you recommend me any good plants to bring the Fuchsias back in the spring. Also will you care to oblige me with a list of five or six very good Fuchsias for growing outdoors?—W. KISS.

[It is not advisable to take cuttings of these now, which also disposes of question No. 2. Cuttings are best taken in early spring from the young shoots. The old plants in the pots will do best if left alone till February or March, when they may be pruned and repotted. Those in the beds may be lifted now and potted at any time, securing a good ball of roots to each plant, potting moderately firm, and standing in half-shady place, giving a good watering also. With the arrival of frosts of any severity place under protection. The following are all good kinds: Singles—Jules Ferry, Inimitable, Jeanne d'Arc, Lord Roberts, Try Me On, General Garfield, Rose of Castille, and Gazelle very free. Doubles: Phenomenal, Ballet Girl, Gipsy Queen, Mrs. H. Cannell, Nelly Morton, Avalancho, and Frau Emma Topfer.]

Heating frames (7733).—You may not only carry your pipes under a pathway for 12 feet with success, but for 1,200 feet with equal success, provided the work is efficiently done and the requisite boiler power at hand. In carrying pipes underground it is necessary to observe that the pipes be not buried in soil or in ashes, but that they lie clear in a trench made for the purpose. In crossing the pathway the least possible rise will suffice, particularly as you have so much rise in the frame. At the same time, you must have a rise, say of not more than 1 inch in the 12 feet. In this case it will be essential that you have a valve in flow and return pipes, otherwise all your heat will go to the higher frame. The best position for the valves will be in the first pit, or just outside the pit wall where they could be worked without any inconvenience. By placing the valves in this position it will be possible to warm the frame quite easily. Naturally, in severe weather you will have to open the valves, and you may do so in proportion to the severity of the weather. In any case, the valves at no time need be more than half open. As your boiler is large enough, it matters little whether you have 3-inch or 4-inch pipes; the latter have, of course, the greater heating surface, and, if this does not exist, it simply means that the pipes must be heated to excess to make things equal—that is, to produce the requisite heat. Therefore, with small pipes and greatly reduced radiating surface, you are constantly expending more money in fuel, while with larger pipes and the larger radiating surface you have a slightly increased expenditure at the start, with the minimum cost for fuel afterwards. In brief, the larger pipes are not only the more economical where they can be used, but the more satisfactory in results also.]

ROSES.

SIX GOOD WHITE TEA ROSES.

White flowers are always welcome, and a white Rose is doubly so. The Camellia has no rival; the Tuberose, Gardenia, Eucharis, and others, although white and sweet-scented, are apt to be bruised so very much more than a Rose that, although they are indispensable flowers when making up any floral designs, they are not so generally preferred as a good white Rose. As the planting season will soon be with us, a list of half a dozen or so may be of service to intending planters.

NIPHETOS, though introduced in 1843, is still one of the finest white Roses we have, and would be in every collection, whether for indoor or outdoor culture. Of free growth and flower, and always opening well, Niphetos will always be a grand white Rose. The buds are long and pointed, and as the flower ages it changes to the purest white colour imaginable. There is also a climbing variety of this kind, and which is also extra good. In every respect except growth it is the exact counterpart of the type. The growth is very rapid, and it will cover a large space as quickly as any Rose, while the

HON. EDITH GIFFORD, sent out by Guillot in 1882, cannot be described as a pure white Rose. It is a flesh-white, getting purer as it ages; a wonderful Rose to stand when out or upon the plant, and of medium size. This is a very useful Rose for the open border or in pots. It is rather more subject to mildew than the majority of Roses, but when well established it will grow away very freely and bloom from every shoot.

DEVONIENSIS is the oldest of the lot. This Rose was sent out in 1840, and is still one of the best. It is, like E. Gifford, flesh-white in its younger stages, getting less so with age. It is very large and full, and possesses a perfume peculiarly its own. The old variety is short and stout in habit, but it has produced a very strong climbing sport, which is grown under the name of Climbing Devonensis. This is indeed a grand Rose when allowed to grow at will. Many complain of this variety growing too strongly and flowering in a scanty manner, but give it room, and only remove a little of the wood that has flowered to leave more space for the remainder, and there will be no need to complain of its shy blooming. A warm and somewhat dry wall and border are best for this Rose.

to from two to four eyes, according to their strength, cutting back the weakest oven to one eye or bud. The long growths, as we said before, should remain as they are, then after they have blossomed you can remove one or two entirely to make room for other similar growths. It is a mistake to severely cut back Tea Roses growing under glass unless they are very vigorous climbers and encroach too much on the space available. We have known such kinds as Mme. Lambert, Souvenir d'un Ami, Perle des Jardins, etc., almost cover a roof of a lean-to greenhouse, and, of course, abundance of blossom is obtained from such kinds when the more vigorous growers are almost flowerless owing to their restricted areas.

The **Maréchal Niel**, which lost its foliage in the summer and is now making new growth, must not be interfered with at present, but we should advise you to give the house as much air as possible by day, and even by night, provided frost is kept out. You will obtain some early flowers from these new growths if you can keep them growing steadily, but there must be no check. Should you be unable to give such treatment owing to the Vines being in the same house, the best plan will be to leave the plant untouched at present, but later, when you start the house, cut back the lateral growths and retain the long ones, as advised for other kinds.]

NOTES AND REPLIES.

Rose Pride of Waltham.—Permit us to draw attention to an error in GARDENING ILLUSTRATED, October 4th. The photograph on page 409 is obviously not "Beauty of Waltham" (bright cherry-red). We happen to know the photo as being one taken in our Rose gardens by Mr. Mason-Good, and the variety is "Pride of Waltham" (deeliest flesh colour).—**BENJ. R. CANT AND SON.**

Roses in October.—I do not know if these Roses are worth notice, but I have never had such before on the 1st of October. Of course, most of them are past their prime, but you can judge of what they have been.—**HENRY MILLER, Parkia, Chiswick, W.**

[A very beautiful gathering, mostly of H. P.'s. Roses this year have been very fine late in the season, as was evident at the last meeting of the R.H.S., at the Drill Hall. Those who grow the Teas may, if the season is favourable, always have a fine display in the autumn; in fact, we think the colours are in many cases richer, the flowers, owing to the cool weather, not being scorched in any way.—**ED.**]

Roses for four beds (W. H. Manning).

—We append names below, five varieties each of the four colours mentioned, and have kept in mind that you have a preference for Roses with long buds:—**White:** Gloire Lyonnaise, Margaret Dickson, White Maman Cochet, Hon. Edith Gifford, Souvenir de S. A. Prince. **Dark red:** Mme. Victor Verdier, Victor Hugo, Eugene Furet, Crown Prince, Prince Arthur. **Yellow and apricot:** Mme. Hoste, Mme. Falcot, Mme. Ravary, Gustavo Regis, Jean Pernet. **Pink:** Caroline Testout, Mme. Abel Chatenay, Mme. Jules Grolex, Maman Cochet, Mrs. John Laing. Provided the fruit-trees, whose stems you wish to clothe with Roses, are not too large, we can recommend for the purpose:—**White:** Purity; **dark red:** Mons. Desir; **yellow:** Bouquet d'Or; **pink:** Climbing Belle Siebrecht. You must take care in summer that the roots of the Roses planted near these trees do not suffer from want of moisture and nourishment. It would be well to make a saucer-like cavity around each Rose, so that liquid-manure, when given, may find its way to the roots. The colours of the Tufted Pansies you propose to plant beneath the Roses would make a very pleasing contrast.

Climbing Roses for S.E. wall.—I would feel obliged if you would recommend me six good hardy wall Roses for a south-east aspect, wall 16 feet high, rather light soil, but the border will be well prepared before the Roses are planted, using fibrous loam and well-rotted manure. Do you recommend the addition of some burned refuse? I should like red, pink, yellow, and white Roses. I have already got Marie Van Houtte, Climbing Devonensis, Lamarque, and Catherine Mermet. I have tried to grow La France and President, and both failed, also Maréchal Niel. My garden is exposed to the south-west wind.—**S. A.**

[If you prepare border as you describe, you should be able to grow La France. Procuro a

Rose Devonensis. From a photograph sent by Rev. Hugh S. Griffiths, Gainsborough.

flowers are borne in the greatest profusion throughout the whole length of the shoots.

SOUVENIR DE S. A. PRINCE is probably the next best white Rose. This was sent out by Mr. Prince, of Oxford, in 1880. For general usefulness it runs Niphetos closer than any other white Rose. It is of good growth, free blooming, and sweet-scented. Like Niphetos, it invariably opens well, and is also grand indoors or out. This is a sport from another very good and popular old Rose, Souvenir d'un Ami, and originated both in this country and in America. The American production is named The Queen, and in every way resembles the one introduced by Mr. Prince.

THE BRIDE is a sport from Catherine Mermet. The flower of The Bride is large and full, besides being very sweetly scented. When young this grand Rose is pale lemon in colour, but gradually gets white with age. To any one who knows Catherine Mermet, The Bride may be briefly described as a white type of it, with a trifle stronger constitution.

BORLE NEIGE was distributed by Lacharme in 1867. It is a grand grower and bloomer, pure white except for a touch of pink on the edges of young blooms. This, however, is lost with age, because as the flower opens, its petals reflex and this characteristic is hidden, leaving a perfectly-shaped and very hardy pure white blossom.

The Rev. H. Griffiths, Gainsborough, who sent the photograph from which our illustration was prepared, has kindly sent us the following notes: "For several years the plant bloomed very meagrely owing to hard pruning by a jobbing gardener. This year, however, I have merely shortened the shoots, and when the photograph was taken it had considerably over 200 blooms—a 'thing of beauty' indeed. At the time of writing (end of July) it is developing a beautiful second lot."

ROSES IN VINERY.

I HAVE just taken a house with large vinery. In the vinery are some Roses—Teas, I think—against back wall. They have thrown long shoots some 8 feet long, stout and strong. I do not understand the pruning of Roses under glass. Should these shoots be shortened now and nailed to the wall? A Maréchal Niel, trained to glass, got badly sun-scalded early in the summer—leaves shed—now making fresh shoots and foliage. What shall I do with it?—**TION.**

[It depends upon the variety as to how your Roses should be pruned, but in the absence of that knowledge we should advise you to leave the long shoots produced this summer unpruned, unless it be to take just a few inches off their extreme ends. Spread them out as much as possible to finish the ripening. If you are giving this house artificial heat early, then the plants must be looked over in November, and the lateral and small shoots pruned back

plant on its own roots or budded on the seedling Brier, and prune it but very little. Caroline Testout would be another excellent pink. Rather stronger growers of this colour are Pink Rover and Climbing Captain Christy; the former has a lovely bud, and its blossoms are very fragrant. A good crimson kind would be Ards Rover, and Grusa and Teplitz would also be a very suitable kind. Belle Lyonnaise would be a splendid pale yellow, and Billiard and Barré a good deep yellow. This latter has a richly-coloured bud, and will be in much request when better known. White varieties of good quality are Gloire Lyonnaise and Mme. Alfred Carrière—the latter rather rampant, perhaps, for a 10-foot wall, but it flowers freely even if its growths are somewhat restricted. If the other side of the wall is on your premises, such a Rose as this would have a beautiful appearance if its growths hung over on this side after they had reached the top of the S.E. side.]

Budding Roses.—I observe in your issue of September 6 an enquiry respecting budding Roses. It may be of interest to your readers to mention a way of removing the wood in preparing the bud for insertion which I have found effective in preserving the eye from injury, as well as a rapid and safe method of operation. Slightly raise the bark above the bud, and insert between it and the wood a loop of strong horsehair or silkworm "gut," then, holding the wood and bark together firmly, draw the loop downwards, when it will separate the bark as perfectly as could be done by a knife, and without any injury to the bud.—ARTHUR MAW.

ROOM AND WINDOW.

GREVILLEA ROBUSTA FOR ROOMS.

This is a hard-wooded greenhouse plant, very easily raised from seed; but to have it available in the shortest time the plants require to be raised in heat. If the seed is sown in February in a temperature of 70 degs., and the plants are grown on in the same house, they will be large enough for use in six months. When once they have attained to a suitable size they should be kept in a greenhouse temperature and have plenty of air, and a thin shade on the glass to keep the leaves of a good colour. If there is no heat available the plants may be raised in the greenhouse, but they will be longer in getting to a suitable size. In such cases the 1st of April will be soon enough to sow the seed, and it must be put in the warmest corner in the house. As only a few plants will be required, the seed may be sown in a 6-inch pot; this should be filled with sandy soil, which must be kept moist by gentle watering. As soon as the seedlings are large enough—say, 2 inches high—they should be put singly into pots 3 inches in diameter, and when they have filled these with roots a shift into 5-inch pots will be necessary. With careful management, the plants will be large enough for use in the autumn, and, if they get a larger pot in the spring, and occupy an airy position on the greenhouse stage, they will last two years for table work. If they are to retain their bottom leaves they must not be crowded at any time, nor must the roots suffer from want of water. Taking into consideration the time they remain of a suitable size, and the little trouble necessary to raise them

there is no better table-plant grown. The annexed illustration represents a *Grevillea* as grown in a small pot for Covent Garden Market.

UNSEASONABLE USE OF FLOWERS.

If one may judge by many florists' shops, the flower-loving public are to have Lily of the Valley, Spiræas, Azalea mollis, and many Lilies and other things the whole year round. Surely we have enough variety in plant life not to necessitate this. I doubt, beautiful as the Lily of the Valley is, if the majority of its admirers would not admit that it is most appreciated from Christmas till the end of June. The same holds good with most things. What advantage can there be in trying to get Violets in bloom all the year round? Regarding our food, there are but few things we do not tire of. Good as many fruits are, we enjoy them most when they first come in. This is clear to market growers, as much higher prices can be obtained for most things when they first come in. Many years ago I had a weakness for

Grevillea robusta in a small pot, as grown for Covent Garden Market.

growing *Chrysanthemums* over as long a period as possible, and the same with a few other things. I soon tired of this, as they became too monotonous. I fail to see the advantage of spending a lot of labour on growing early *Chrysanthemums* in pots, while there is abundance of beautiful hardy flowers that can be had from the open garden. Rather would I grow kinds to brighten up conservatories or for cutting from through the last six and first six weeks of the year. J. CROOK.

CHRYSANTHEMUMS.

Early-flowering Chrysanthemum Mme. Marie Masse.—One of the best of garden *Chrysanthemums* is to be found in Mme. Marie Masse, a lilac-mauve. It commenced to bloom with me at the beginning of September, and from it I have cut many useful blossoms. *Crimson Mme. M. Masse* is equally beautiful, and is a desirable colour amongst early-flowering sorts for a border, whilst yet a

third, said to be a seedling, is *Orange Masse*, extremely dwarf, and commencing to bloom early in August. Plants of these, pinched once in May, make short, sturdy pot-plants, and often fill a gap in the greenhouse in September.—TOWNSMAN.

Thread-petalled Chrysanthemum.

—These are extremely graceful, and therefore well adapted for cutting. Many of them bloom after the mid-season varieties have come and gone, and one can cut blooms of them in December and January. A good number of them are dwarf, and, on this account, also, are suitable for amateurs' houses. Good varieties are: *Golden Shower*, reddish-bronze, fine, delicate florets; *Mme. Poiret*, pure white, late blooming; *Sann Caswell*, pink, late; *What Not*, pale yellow, curling florets; *Mignonette*, pale yellow, tipped bronze; *Novalty*, rosy-white; and *Titsuyetin*, silvery pink.—WOODBRASTWICK.

Outdoor Chrysanthemums.

—This spring I invested in a dozen early-flowering *Chrysanthemums*, planting eight in a border and four in pots. They have not done much, probably because they were severely set up by an unexpected gale in September. However, I did not expect much the first year. One or two are in full bloom, more in bud. What I would like to know is (1) will those in the border stand the winter without shelter? Kinds are *Crimson Pride*, *Crimson Mme. Masse*, *Flora*, *Harvest Home*, *C. Denny*, *Ly Stark*, *O. J. Quintus*, and *White O. J. Quintus*. I could cover them with straw after they die down. This is a cold district, with long frost usually after the New Year. I had regard to those in pots, but standing out, shall I place them out so long as the weather is open, and shall I cut them down when doing so? Or would it be better to keep them in pots in a frame until the spring? I have not room for them in the greenhouse now I have got the late-flowering kinds in. (2) My *Crimson Masse* seems to have named? Trusting you will be able to afford space for brief replies.—M. FALCONER, Elder Bank, Dux, N.H.

[You must lift those in the open after cutting down and put them into a box, standing them in a frame and protecting from severe weather, or putting into a house from which frost is excluded. Keep them thus till the spring, when you ought to divide them and pot them, putting them out again in May. 2, Cut down those in pots and store in the same position until the spring, when they can be treated in the same way. 3, We cannot say without seeing the flowers.]

GARDEN PESTS AND FRIENDS.

Thrips.—The habit of forestalling enemies is a very desirable one for cultivators to follow, especially when dealing with those troublesome insects called thrips. One may neglect scale and bug for a few days with no other immediate result than an increase in their numbers; but to let thrips get the upper hand means destruction to the foliage and a lowering of the vitality of the plant. These little masters require to be looked after now, when fires are necessary in plant-houses. Tobacco fumigation is the best remedy, to be followed up in such cases on alternate evenings till three generations have been given.

Insects on Apple-trees.—My Apple-trees are infested this spring with caterpillars. Will you kindly tell me how to make a lime-wash to be applied to stems and branches? Should it be applied hot?—ESTERHILL.

[For cleansing the stems and branches of all kinds of fruit-trees there is nothing better than the caustic alkali solution, for making which the following is the formula. If you only wish to make a small quantity, dissolve ½ lb. of caustic soda in a gallon of water, then add ½ lb. of commercial potash (pearlash), stir well, then mix both, adding enough water to make 5 gallons of solution. Apply to the large stems with a brush, to the small branches in the form of spray with an engine or syringe when the trees are dormant. Be careful that it does not touch the hands or the clothes.]

Tomatoes, eelworm in (Wood).—Your Tomatoes and Cucumbers have been badly attacked with the root-knot eelworm, and it is useless attempting to restore the roots to a more healthy condition. At once clear out the affected plants and every particle of soil and manure in which or near to which they have been growing, and start afresh with clean young plants and good fibrous loam. If growers would only use far less soil, top-dressing when necessary and feeding and watering freely, which are only possible when small quantities of soil are used, we should hear far less of the destruction caused by the eelworm.

TREES AND SHRUBS.

SOLANUM JASMINOIDES.

SOLANUM JASMINOIDES is surpassed by none of its race in the beauty of its flowers and in the lengthened period through which it blooms, it having been known to have been in bloom for a period of ten months. It is, naturally, only during exceptional seasons, even in the favoured south-west, that such an extended period of blooming can be looked for, but five or six months' flowering may be confidently expected, unless in cases where the plants have been cut hard back by exceptionally severe and prolonged frosts, when the commencement of their blossoming is delayed by fresh growths having to be made from the hard wood before flower-production is possible. When planted in good soil the growth of this subject is very rapid, a small rooted layer forming a plant that

by either of the first four. For cutting, this *Solanum* is valuable, its long, flower-laden sprays being especially effective when drooping gracefully from a tall vase.

NOTES AND REPLIES.

Hardy evergreen shrubs.—Would you kindly furnish me with a list of what you consider the twelve choicest evergreens, variegated or otherwise, suitable for the border of a front garden, say, 10 yards square?—**J. F. C.**

[Holly, Aucuba, *Choisya ternata*, *Olearia Haasti*, *Osmanthus ilicifolius*, *Andromeda floribunda*, *Skimmia*, *Kalmia* and *Rhododendron* (these two must have peaty soil), *Box*, *Berberis*, and *Yew*. You could also try the *Tamarisk*, and, as an edging, some of the hardy *Heaths*.]

Shrubs doing badly.—I planted about two acres in front of my house three years ago with all sorts of flowering shrubs. The ground was double dug before the plants were put in, but the grass has grown very thick

Rose climbing up it, as described on page 366, and handsome flowering shrubs scattered about, four good *Tree Paeonies* amongst them.—**R. S. STANBEN.**

[In order that you may partially make your own selection, we here append names of 20 good flowering shrubs, with their approximate heights, season of flowering, and colour of the blossoms. With your four *Tree-Paeonies* this will give you a choice of two dozen. *Berberis Darwinii*, 6 feet, May, orange-yellow; *Berberis stenophylla*, 11 feet, May, golden-yellow; *Cytisus Andreanus*, 6 feet, April and May, yellow and reddish-brown; *Doutzia crenata flore-pleno*, 6 feet, June, pinkish; *Forsythia suspensa*, 11 feet to 7 feet, March and April, yellow; *Hamamelis arborea*, 8 feet, January and February, yellowish; *Hydrangea paniculata grandiflora*, 4 feet to 5 feet, August, creamy-white; *Magnolia stellata*, 3 feet, April, white; *Philadelphus Lemoinei*, 4 feet, June, white; *Rhus cotinus*, 5 feet, July, purplish-brown; *Rubus deliciosus*, 4 feet, May, white; *Spiraea arguta*, 4 feet, April, white; *S. japonica*, 5 feet, June and July, carmine; *S. j. alba*, 2 feet, June to August, white; *S. j. Anthony Waterer*, 2 feet, June to August, crimson; *S. prunifolia flore-pleno*, 5 feet to 6 feet, April and May, white; *Viburnum plicatum*, 5 feet, May, white; *Weigela Abel Carriere*, 6 feet, May, rose; *W. caudata*, 6 feet, May, white; *W. Eva Rathke*, 5 feet, May to July, red.]

Bark of trees splitting.—When I wrote to you to inquire what might be the cause of the bark of my trees splitting, I did not give my own opinion; but as I differ from your correspondent "G.S.S.," who thinks it was frost, will you allow me to state the conclusion I have arrived at. I think the cracking is the result of a hot sun's rays and deficiency of moisture in the ground, because all the cracks are on the south side, both in my garden and in many nurseries where I have also seen them; and the last two summers have been extremely hot and dry. Further, the cracks and peeling off of bark become much worse when the trees are planted nearer to full grown ones, the roots of which may—as in *Elms* or *Poplars*—extend to them and suck up the rain. That frost is not the cause I believe, because I saw lately a long avenue of trees planted about two or three years ago at Cordova in Southern Spain, every one of which was injured thus, but only on the southern side. In Cordova there is a completely southern climate, and rarely frost; moreover, at my own residence on the south coast the climate is mild in winter.—**A. S. BURNELL.**

Raising hardy Heaths.—When staying at Plymouth this season I was very much struck with the Heather, of which I enclose a few sprigs. At the same time I took some seed. Will it grow inland? When, and what position had it better be sown in?—**H. CRICK.**

[The specimen sent is *Erica Tetralix* (Bell Heather), which occurs in a state of nature more or less plentifully throughout the greater portion of the British Isles. It will thrive perfectly inland as well as in proximity to the sea. From the minute character of the seed particular care is necessary in sowing it. In sowing it artificially, the quickest way is to take some shallow boxes or pans, and place some broken crocks or some other drainage material in the bottom, then fill to within half an inch of the rim with sandy peat passed through a sieve with half an inch mesh. This must be pressed down firmly, made quite level, and given a thorough watering through a fine rose. While still wet sprinkle the seed thinly thereon, and over it just a very little fine soil of the same quality as that with which the boxes or pans are filled. After this place in an ordinary garden frame, and keep watered always through a fine rose, when it will soon grow. When the young plants are about an inch high transplant them into pans or boxes as those in which the seeds have been sown, and when they become crowded plant them out. If no facilities exist for sowing the seed in this way it may be sown in the open air, choosing for the purpose a spot fairly sheltered both from cutting winds and direct sunshine. Should you have a common in your neighbourhood on which the Heather grows, a barrow-load of that soil mixed with the ordinary soil of the border will suffice. Take care that the seed after sowing is not allowed to get too dry, and that a fine rose is used in watering it, as it may otherwise, from its minute character, be

A flowering spray of *Solanum jasminoides*.

will reach to the eaves of a two-storied house in three years. For pergolas and archways this climber is equally valuable, its white flower-wreaths festooning them with graceful trails for many a week. In the northern districts of England it is, perhaps, of too tender a constitution to withstand the rigours of the climate in the open air, though it has been known to flourish in Dorsetshire. Where it is deemed unwise to trust it in the open, a situation in a glazed verandah or some such light and airy structure may be utilised for its reception. *Solanum jasminoides* lacks one merit, that of perfume, possessed by the *Wistaria*, *Jasmine*, *Honeysuckle*, *Clematis Flammula*, *Stauntonia latifolia*, and other flowering climbers, but its extended period of blossoming renders it infinitely more decorative in the garden than are the possessors of the more fugitive blooms already named, though, during their comparatively short flower season, few will be found to cavil at the picture presented

round them, and they are not making as much growth as they should, whilst the smaller plants, such as *Fuchsia*, are rather smothered. Can you advise me how to keep down the Grass? I cannot very well have the ground dug again, for fear of injuring the roots of the trees; besides, it is expensive work. Would it be any use to cart a lot of peat into the plantation? It might possibly weaken the Grass. I shall be much obliged for your advice.—**A.**

[You can clear the turf away round each tree, say a circle of 3 feet in diameter, and on this place a good mulching of manure, which will benefit the trees and encourage growth. You ought to do this soon, so that the winter snow and wet may wash the goodness out of the manure down to the roots of the trees. Keep the space clear always, and you will soon see a change in the shrubs. If the summer is dry water well and apply another dressing of manure.]

Flowering shrubs.—Will you kindly suggest about a dozen good flowering shrubs for a small piece of lawn, 20 yards by 10 yards? About three-fourths of it gets the sun (when there is any) all day; the other fourth, only the early morning and evening sun. I thought of having a lit pole for the centre, with *Honeysuckle* or a

washed away. In permanently planting this Heath it must be borne in mind that it grows naturally on breezy uplands, hence it should have as airy and sunny a spot as possible.]

GARDEN WORK.

Conservatory.—A little ventilation at night should be given as long as the Chrysanthemum remains one of the principal features, but cold draughts should be always avoided. Most gardeners nowadays grow more Chrysanthemums than can be accommodated without overcrowding, though this may be a good fault, as it permits of a selection being made; but it is not well to crowd plants in too closely, so as to destroy their foliage. Where there are numbers of glasshouses the plants can be arranged in separate sections until they are ready for the conservatory. It is quite certain that the late-flowering Chrysanthemums, if they are required to bloom at Christmas or later, must be kept cool. The latest kinds are still outside, but within reach of shelter in case of sudden frosts or strong gales of wind, which often do damage even when the plants are well supported. If the buds of Camellias have not been thinned attention should be given to them now where crowded. Weak soot-water is peculiarly suitable for Camellias and large specimen Azaleas which may require help. The water-pot should be in the hands of a very careful person now. Numbers of men and boys commence a gardening career and never find a permanent place or make their mark in it, because they are entirely devoid of the faculty of taking pains, and plant life is too important to be trifled with and neglected by careless people. The climbers now will have been reduced to the normal winter condition. There will, of course, be flowers on many things, and there will be others coming and going. Bougainvillea glabra will flower in the conservatory till late in autumn. Heliotropes, Ivy and other Geraniums, and Tea Roses planted out are also full of blossoms. Hahorthamnus in variety, Abutilons that were pruned back in July, will now be full of blossoms, and buds coming on in succession. These and other things of somewhat similar character may be regarded as the framework of the house, inside which will be grouped as tastefully as possible the pot stuff brought from other houses. The outside flowers will soon be over or in a non-presentable condition, and it becomes incumbent on the gardener to make the most he can of his glass structures.

The unheated conservatory.—As a rule, the owner of the cold glass-house, if he be a person of resource, and gifted with a philosophical temperament, will not be envious of those who grow more tender plants, and sit up at night to attend to the fires. There are very pretty plants which only require protection from the wind and rain in winter. To mention only a few things, Chrysanthomums, regarded merely as ornamental objects, and not too highly fed, will do very well with a glass roof over them. It is the highly-fed blooms which decay quickly if there is any dampness in the atmosphere. Very pretty also are several of the Japanese Grasses and shrubs in the cold-house. Well grown bushes of the Laurustinns and winter-flowering Jasmines require only shelter from the weather. The Christmas Roses are a charming feature in the cold-house. I have seen them in tubs very large and full of blossoms at Christmas. Bulbs potted early will flower early without forcing, especially such hardy things as Snowdrops, Crocuses, Narcissi of various kinds. Some of the pretty early-flowering alpine plants will be charming in a cool-house. Good potsfull of the new double-flowering Arabis will have some value for cutting, as the spikes are larger and longer than in the type. A very great deal can be done in a cool conservatory, especially if it is joined on to the dwelling and is not too small. The boiler and pipes almost double the ordinary cost of the structure and boilers wear out, and the cost of fuel and attendance are considerable.

Roses for forcing.—Strong plants, potted up now or towards the end of the month, should be placed on a coal-ash bed until tree-leaves in sufficient quantity can be

obtained to fill a pit, the Roses then to be pruned and plunged in the leaves to encourage new roots to form. Plants treated in this way will provide an abundant crop of flowers in March without much forcing. To obtain early flowers, the plants must be established in pots now, and be pruned ready for starting. There is no better medium for the encouragement of the production of both roots and growth, which means flowers in plenty later, than a bed of leaves in sufficient bulk to produce gentle heat, into which the pots can be plunged. The genial vapour arising from the bed of leaves gives force to the growth and size and brilliancy to the blossoms, and there is, under such circumstances, less trouble with insects.

Winter management of fruit-borders.—A very dry border in winter is injurious and unnatural, especially in the case of Peaches and other stone fruits, which make new roots in winter. Vines do not make progress in root formation after the leaves fall, and, therefore, they do not suffer so much from a dry condition of the soil as where life is more active. Though even Vine-roots in a perfectly dry state cannot carry on their work so well as when reasonably supplied with moisture, still many of the rich outside Vine-borders would be better if covered in winter and more freely supplied with water during the growing season in summer. The falling of the buds in Peaches and Nectarines might in most cases be traced to extreme dryness of the borders in modern Peach-houses during autumn and winter, especially in autumn whilst the buds are maturing. At this time, too, a little weak stimulant may be given with advantage.

Late vinery.—A little warmth in the pipes will be necessary to finish ripening of the late kinds and to thoroughly mature the wood. No leaves should be permitted to touch the glass to conduct the moisture down among the bunches. If the Grapes have to hang any time on the Vines, the borders should be mulched with clean straw to keep down dust and arrest evaporation. Use the scissors the moment a bad berry is seen.

Window gardening.—Cyclamens will do well in a light window. The earliest seedlings are now in 5-inch pots and coming into bloom, and, with careful management, will flower all the winter. Winter-flowering Heaths are not difficult to manage when the necessity for careful watering is understood. A pot or two of early-sown Mignonette just coming into bloom may be added. The window-boxes outside are getting shabby, and arrangements should be made for refilling them. The cheapest things are yellow Wallflowers and Forget-me-nots. Seedling Pansies are just coming into bloom, and may be mixed with Tulips.

Outdoor garden.—Sow a few Sweet Peas on a well drained site for early flowering, covering about 2 inches deep. In cold, clay districts sow in pots in cold-frame. After the available frames are filled up with Violets, which have been specially grown for the purpose, the remainder of the plants may be planted on a warm south border or in front of a thick hedge. A border on the south side of a Yew hedge will be a capital place. Get the positions for the early-flowering bulbs prepared as soon as possible. Crocuses, Snowdrops, early-flowering Narcissi, and early Tulips should be planted soon to flower well. The bulbs in the ground now are busy making roots. Plant spare bulbs of Snowdrops and Crocuses in retired spots on the lawn. They are lovely under trees, as they flower before the trees are in leaf in spring. Baro places under trees may be planted with the small-leaved Ivy, and the bulbs planted with a dibble among the Ivy. The Winter Aconite is lovely in a broad mass on a shelving bank. The Holly-leaved Berberis, a good plant for massing under trees, should be pruned annually after flowering, and then it forms a beautiful groundwork all winter, and the flowers in spring are among the brightest things in the garden. A decision will soon have to be come to respecting the Carnations. If the layers are well rooted and the beds ready, plant now, reserving duplicates to make good losses, if any. If the layers are not sufficiently rooted, they may either be left as they are on the plants, or potted up and placed in frames.

Fruit garden.—The best way of keeping Strawberry plants intended for forcing is to plunge the pots up to the rims in ashes. They will there ripen and rest until January or when forcing begins. They ought to be covered with old lights when severe or very wet weather comes. At present they are better exposed. In gathering Apples and Pears, the latter especially may have the season prolonged by gathering the ripest fruits first. Take the fruits from the south side of the trees first. Of course this can only be done in the case of pyramids or other trees in the open garden; but even with trees on walls the season may be prolonged by gathering the fruits first which have the ripest appearance. The practised eye can easily make a selection, and the season of any Pear may easily be extended by placing a few fruits in heat for a few days. Something more might be done with Blackberries. Give them a deep, well-worked soil, and put up a rough fence with Larch poles and wires, and let them ramble over it, cutting away the old canes or some of them after fruiting. I was in a garden lately where the Wineberry was fruiting very freely, and it was highly spoken of, more especially as a cooking fruit. Sites for young fruit-trees should be prepared soon. For early bearing, Apple-trees are best on a dwarfing stock. The English Paradise appears to suit pretty well all kinds of Apples. The Quince for Pears will suit some, but not all soils. The Quince loves moisture.

Vegetable garden.—This is the real time for taking up and storing roots of all kinds, except Parsnips and Salsify, which keep best in the ground. Jerusalem Artichokes are usually left in the ground, and the surface covered with litter to keep out frost, so that they can be lifted as required. Late Celery should be carefully earthed up in dry weather, when the soil, placed near the plants, can be well broken up with the fork. The sides of the ridges should be made true and smoothed down with the spade to throw off the rain. There will be a tendency in the green crops, Broccoli especially, to make luxuriant growth, and the plants of the late kinds will stand a better chance of passing the winter safely if they are laid down with their heads to the north. Cauliflowers are abundant and good, and, as frost may come at any time now, the hearts of those plants which are turning in should be protected by their own foliage. Later on the covering of foliage will not suffice, and the plants must be lifted with balls and planted elsewhere, where protection can be given. Thoro will in most cases be a considerable demand for salad plants, of which the most important are Lettuces and Endivo, which should be tied up to blanch. A supply also should be coming on in frames.

E. HOBDAV.

THE COMING WEEK'S WORK.

Extracts from a Garden Diary.

October 15th.—Moved several evergreen trees and shrubs to fill central positions in new shrubbery. They had been cut round last year, and the trench filled with good soil, into which the fibres have entered. This is the best way to make sure work with large specimens. Sowed a lot of Fern spores, chiefly Pteris in pots of rather heavy loam made firm. The pots are placed in shallow pans in frame and kept close, with a temperature of 50 degs. to 55 degs. The last of the late Chrysanthemums have been placed indoors to be out of the wind, but lights will be left open all night.

October 16th.—Planted out more Cabbages and Brown Cos Lettuces. Earthed up late Celery. Apples and Pears are being gathered from time to time as they ripen. Azaleas, just arrived from Belgium, have been potted and placed in cold-pit for the present. The August-sown Cauliflowers have been pricked off into temporary pits where some lights can be placed over them. Another range of the same class of structures has been filled with Strawberries intended for forcing.

October 17th.—We have just finished planting late Tulips. Surplus bulbs have been planted in various parts of the grounds, and some of the double Daffodils have been put in along the hedge side in the orchard. We have root-pruned several Pear-trees that have made rather too

much wood. Several old trees have been condemned and will be grubbed up and the soil changed in readiness for young trees.

October 15th. — Rearranged conservatory, adding a considerable number of early-flowering Chrysanthemums in groups about the house. Fuchsias and Ivy-leaved Geraniums planted out are still very effective. Roses intended for forcing have been pruned, top-dressed, and placed under cover. More bulbs have been potted and fixed for forcing when required, but for the present they are outside making roots, covered with litter. Box edgings on one walk had become a little gappy. This has been taken up and relaid.

October 20th. — Gathered the last of the open-air Tomatoes and placed under glass to ripen. A few of the earliest potted Arum Lilies have been placed in gentle warmth to hasten the flowering, as we want blooms at Christmas. Potted Liliun Harrisii and plunged in Cocoa-fibre. We grow a few retarded bulbs of Liliun longiflorum, as we always like to have blooms of this or some other white Lily, and L. luncifolium is now just over. Potted up Spiraeas of various kinds for forcing.

October 23th. — Sowed Sweet Peas for early blooming very thinly, and covered the surface over the rows of seeds with sifted ashes to keep off mice and slugs. Roses are rather too full of growth to move just yet, but the beds are ready. Duplicates of Carnations planted out have been potted, and will be kept in cold-frames, the pots plunged in ashes before frost comes. Took up main crop of Carrots and Beet and stored in sand. Finished putting in cuttings of Roses.

LAW AND CUSTOM.

Flower show — responsibility of committee for prizes offered. — A flower show was recently held here, and in their prospectus the committee inserted the following condition: "The Society will only be responsible for the prizes so far as their funds will allow." This condition was printed in distinctive type. The committee have not now funds to pay in full the whole of the prize money offered and awarded. In the prospectus two special prizes were offered for competition, and these prizes were given by two gentlemen whose names were set out as the donors in the prospectus. Do these prizes fall within the operation of the above condition or rule, or must these be paid in full? — S.W.C.K.

[These special prizes were given for specific purposes and must be devoted to those purposes. Consequently, if the donors have paid the sums in question over to the committee, the committee must pay those prizes over in full to the competitors to whom they were awarded by the judges. — K. C. T.]

Forfeiture clause in tenancy agreement. — I took a piece of ground for nursery purposes for the term of five years at a rent to be paid quarterly, but when the first quarter's rent fell due I was unable to pay it. There is a clause in the agreement that if rent is in arrears for three days the agreement is cancelled. After my tenancy had lasted six months my landlord told me that if I continued in possession he should treat me as a trespasser. He has now sued me for six months' rent. Can he recover it? I have some shrubs and a greenhouse (not erected) on the ground. Can I counter-claim against him? — T. M. W.

[Yes, your landlord can recover the rent. It is not clear whether he has given you formal notice of a forfeiture, but I suppose he has done so. It is clear that you have forfeited your term, and he may re-let the place when he chooses. You have no ground for any counter-claim against your landlord. You should have taken your unerected greenhouse away. — K. C. T.]

Trespass by builder. — I am the owner of a small plot of garden ground (freehold), which adjoins a field on which a house is being built. My garden and the field are divided by an oak post-and-rail fence. During my absence the builder, without my permission, removed three lengths of the fence (my property), the more easily to build the back wall of a stable. The fence was very roughly removed and greatly damaged—in fact, is now practically useless—and the two ends of the fence left standing are without supporting posts. On my remonstrating with the builder, he seemed to think he was perfectly within his rights (he said he could not get a perfect building line while the fence was in the way), and, altogether, acted in a very high-handed manner; but he offered to apologise for trespass, at the same time absolutely declining to accede to my demand to pay the value of the lengths removed, which are now of no value to me. Have I any legal remedy? — WORKINGMAN.

[This builder had no right whatever to interfere with your fence. He has committed a trespass for which he is clearly responsible in damages. As he refuses to make good the fence, you should at once sue him in the County Court and claim from him at least double the sum it will cost you to make it

good. Such a man as he is should be taught a sharp lesson, and you can teach him one without difficulty. It is no concern of yours that he could not get a perfect building line without removing the fence—it did not matter if he could not get a line at all. — K. C. T.]

The rating of greenhouses. — Two and a half years ago I took some greenhouses on a yearly tenancy at the annual rental of £2 10s., and the greenhouses are rated to the general district rate at the same rate in the pound (2s. 10d.) as are houses. Is this correct? Poor-rates are made in each half year, but no poor-rate for either of the four half years of 1900 and 1901 was demanded of me until Feb. 25th last, when the assistant-overseer demanded all four half-years' rates at once. In each case the rate in the pound charged was the same (2s.) as is charged upon houses. Is this correct? I have refused payment. If incorrect, what should I do? — GARDENER.

[I presume these greenhouses are occupied by you for trade purposes, and if so they are none the less market gardens because the ground is wholly covered by them. I think, therefore, that the decision in Purser v. The Worthing Local Board governs the matter, and that the rating of the greenhouse to the district rate (I presume it is an urban district) is bad. You may, therefore, refuse payment, and if proceedings are taken against you to recover the rate, you should appear and show cause against the application. As regards the poor-rate, the decision in Smith v. Richmond governs the matter, and the greenhouses are properly rated to the poor-rate at the same amount in the pound as houses. There is no limitation of time as to the collection of poor-rates, and so these four half-year's rates must be paid. Perhaps if you refused and were summoned, the magistrates would refuse to issue their warrant of distress, but probably the warrant would issue. If I were in your place, I should appear at the next audit of poor-rates and state the circumstances to the auditor, as it is clear the assistant-overseer has grossly neglected his duty. I presume no demand notes were ever sent you, for if these were sent, they constituted a proper demand of the rates to which they referred. — K. C. T.]

POULTRY.

Death of young Turkeys (Evan Martin). — It is absolutely necessary that these birds should be kept on a light, dry soil, otherwise the mortality of the chicks is very great, and a Grass field into which a lot of sewage flows is about as bad a position for Turkey keeping as one could possibly choose. This would quite account for the death of so many of the young birds, and they will in all probability all die off if a more suitable run cannot be provided for them. Turkeys are of rembling habits, delighting to wander in search of insects, green herbage, Beech-mast, berries, and so forth, and will thrive upon these things, provided the land over which they wander is warm and dry. So susceptible of wet are the chicks (a sudden shower will sometimes prove fatal) that it is necessary to keep them cooped with the mother for quite two months, the coop being removed daily in dry weather, and placed on boards in a warm outhouse at night during wet weather. Even when well grown, the young birds should not be allowed to roam the fields while there is heavy dew or white frost upon the Grass. Nettles, Turnip-tops, Cabbage, Onions, Dock, and other green stuff, boiled down and mixed with Barley-meal or Oatmeal, form excellent food for the young birds, together with Barley, Buckwheat, Oats, Beans, and Sunflower-seeds, the last in small quantities. — S. S. G.

United Horticultural Benefit and Provident Society — postponement of Annual Dinner. — The Annual Dinner of this society, previously announced to be held on Tuesday, October 5th, has been unavoidably postponed. It will now be held on Thursday, October 16th, 1902, at 6.30 p.m., at the Holborn Restaurant (Threms Room), High Holborn, W.C. Arthur W. Sutton, Esq., F.L.S., V.M.H., will preside.

Photographs of Gardens, Plants, or Trees. — We offer each week a copy of the latest edition of the "English Flower Garden" for the best photograph of a garden or any of its contents, indoors or outdoors, sent to us in any one week. Second prize, Half a Guinea.

This Prize Winners this week are: 1, Mr. W. Jasper, Menston-in-Wharfedale, Yorks, for Liliun festucaceum; 2, Mr. Geo. E. Low, for Polygatum at Mount Usher.

CORRESPONDENCE.

Questions.—Queries and answers are inserted in GARDENING free of charge if correspondents follow these rules: All communications should be clearly and concisely written on one side of the paper only, and addressed to the Editor of GARDENING, 17, FURNIVAL-STREET, LONDON, E.C. Letters on business should be sent to the Publishers. The name and address of the sender are required in addition to any designation he may desire to be used in the paper. When more than one query is sent, each should be on a separate piece of paper, and not more than three queries should be sent at a time. Correspondents should bear in mind that, as GARDENING has to be sent to press some time in advance of date, queries cannot always be replied to in the issue immediately following the receipt of their communication. We do not reply to queries by post.

Naming fruit.—Readers who desire our help in naming fruit should bear in mind that several specimens in different stages of colour and size of the same kind greatly assist in its determination. We have received from several correspondents single specimens of fruits for naming, these in many cases being unripe and otherwise poor. The difference between varieties of fruits are, in many cases, so trifling that it is necessary that three specimens of each kind should be sent. We can undertake to name only four varieties at a time, and these only when the above directions are observed.

PLANTS AND FLOWERS.

Roses and Dahlias (E. D.). — The dressing you propose giving your roses will answer well. 2. After the frost has killed the tops of the Dahlias cut them down and store away, pots and all, in a frost-proof cellar. Start into growth next spring, and grow on in the usual way until planting-out time comes round in the month of May.

Roses for fence (A. B.). — You would find the Rambler roses, such as Felicite-Perpetue, Bennett's Seedling, Aglala, and Crimson Rambler very suitable for such a fence. They would in time grow higher than the height you give, but perhaps you would not mind this. You might also try such as Gloire de Dijon, Mme. Serard, Bêve d'Or, Climbing Devoniana, or W. A. Richardson. Lay a good foundation in the way of good soil, etc., for all kinds of roses, including Chinas and Briers, and you will gain in the end.

Planting Pinks (M. H. Statelmu). — If you have well-rooted plants you should plant at once, 9 inches apart, in rich and well-trenched ground. If the winter is very severe, a little litter should be scattered among them, and in spring the surface of the bed silted and given a dressing of old manure and some guano. If you have to defer planting till spring, commence as soon as the weather permits, and when the plants begin to grow, treat as above with regard to mulching, etc. Dig the Cerastium in in the spring wherever you want to put it.

Galvay Clover (Medicago Fehina) (A. W. Cuppage). — This is a native of the South of France, and was introduced to this country in 1814. Sow the seed early in April in sandy soil in a pot. It will germinate in a sunny window. Pot off the seedlings singly, and you may either grow on in pots, shifting on when needed, or plant out in the open air. The only novelty about the plant is the seed-vessel, because if you begin to open the round half at the point where it was detached from the plant, you will find it unroll in the form of a narrow ribbon-like strip, leaving the seed loose in the hand. During growth it should have abundances of water, otherwise root-rot will probably attack it and spoil the foliage. It will die in the open air, but in pots the pods are more quickly formed, and thus the novelty aimed at in growing this Clover is more safely attained.

Lychnia, Michauxia, and Eremuri (A. Phil. Iydia). — Your specimen is insufficient for naming. Lychnia Haagiana is a true perennial, but is best treated as described by our correspondent, "E. J." In a recent issue. In these circumstances it is among the finest of summer-flowering plants, delighting always in a warm and very sandy soil. The Michauxia is best regarded as of biennial character—i.e., sow the seed from March to May, grow on quickly in 5-inch pots, and plant out in June or July. The plants bloom the following year, and usually perish after the flowering. The Eremuri may be grown in the herbaceous border, but we regard them as quite fitted for this, and better results ensue when beds are devoted to them or the plants isolated in some way or other. They are quite easily grown. October is a good planting time, and we may give a short note dealing with them in time for this.

Potting Aspidistras (C. F. G.). — As a rule these plants do not require repotting every year; in fact, some of the finest examples are those most pot-bound. As to how long a plant may remain without potting, however, has much to do with its condition, and equally how it was treated at the last potting. Given a good, free drainage and a soil not overcharged with fat manure, with firm potting, the plants would be quite safe for two years. The green variety certainly prefers a good soil, while the variegated kind is best in a somewhat poorer soil. In these respects they are by no means fastidious, and the free addition of charcoal will assist in keeping the soil sweet and good. There is no need to place these plants in a window; they are quite content often enough in a dark corner, a fact that renders them doubly valuable as room plants. The variegated form is a sport from the green variety, and not obtained by poor soil, will, however, help to retain the variegation.

Border plants for July and August (Peggy). — The following are all suitable: Rudbeckia Newmanii, 2 feet; R. purpurea (Winchmore Hill var.), 3 feet; any of the perennial Sunflowers, as Helianthus multiflorus pl., H. M. Soleil d'Or, H. M. maximus, H. rigidus in variety; 3 feet; 10 feet high; Verooka longifolia umbellata, 3 feet; blue; Kniphofia in variety; 3 feet high; Monarda didyma, 2 feet; Statice latifolia, 1 1/2 feet; Montrosia, 2 feet, very fine; Scabiosa caucasica and alba, 2 1/2 feet; Helianthus pumilus, 1 1/2 feet; H. autumnale, 3 feet; H. nudiflorus, 4 feet; 1 1/2 feet; H. multiflorus, 2 feet high, giving golden, mahogany, crimson, and chestnut coloured flowers; Phytolacca spicata, 2 feet; Phloxes in great

variety, scarlet, salmon, white, and endless intermediate shades; *Pentstemon Torreyi*, 3 feet; *Phyllis Franchetti*, 2 1/2 feet; *Stenactis speciosa*, 2 1/2 feet; *Liatris*, several kinds, 3 feet; *Zauschneria californica*, 1 foot; *Eryngium* and *Echinops*, any 3 feet to 4 feet; *Cimicifuga oerdfolia*, 4 feet; *C. racemosa*, 4 feet; *C. dahurica*, 3 1/2 feet; with *Anemone japonica*, in red, white, and pink, 3 feet high and more when established. These are a few of the many at the time mentioned.

Sauromatium guttatum (*Inselm* and *P. R. Stevens*).—This needs soil to grow in, the same as most of the Arums, to which it is nearly allied. The temperature of a sitting-room would be sufficient for it, but the unpleasant odour of the blossoms would soon cause its banishment therefrom. This *Sauromatium* is a native of the Himalayas, and succeeds perfectly at Kew planted out in a narrow south border in front of the Orchid-houses. The warmth from the houses prevents it from being frozen in the winter. The firm, solid bulb pushes up a solitary leaf, while the flower-stem (borne generally in the spring) has a peculiarly weird appearance. They are long and tapering, and in colour green, richly barred with chocolate-crimson, and in the end of a dull green hue. As a rule it attracts from its lizard-like appearance, but the odour of the blossoms is not suitable for confined places.

Boxes for exhibiting flowers (E. G.).—The National Dahlia Society's regulation with respect to show boxes or boards for twelve large flowers is that they be 21 inches by 15 inches, be 3 inches high in front and 9 inches in height behind. Generally the flowers are shown on flat boards, which have holes in them, at equal distances apart, and into these are let metal tubes to hold water for the flowers. The boards are supported on legs front and back, which will fold close to the board. Then in a box 28 inches deep three or four of these boards with the flowers in them can be carried to a show. In the box should be narrow ledges on which the boards slide to keep them secure in travelling. Asters may be shown on similar boards if found convenient, but if less long by 4 inches and deep by 2 inches they are ample. Roses are best shown in boxes 4 inches deep and 21 inches by 16 inches in area. These should have a top, but tubes should be shown at proper distances apart, then well packed with green moss. So shown the flowers keep fresh a long time. There is no such book as you ask for.

Dividing Kniphofia (H. H.).—The best time in the whole year for dividing *Kniphofia*, large or small, is in March or April, just as growth begins. At this time dig up the plants as carefully as possible, then lay it on its side, and by plunging a single prong of the garden fork into the solid portion of the clump, gently wrench it asunder in a direction opposite to which you place your left-hand resistance. Repeat the operation on the divided pieces, inserting the fork in the centre of the woody portion each time. If these are not small enough, repeat the division yet again, and the portions will be ready for replanting. With these things it is better for the ensuing flowering if the divisions are made rather small or medium-sized, and in place of planting back a solitary plant make a group of some three or five. In this way you ultimately establish an important clump, larger and decidedly more imposing than a single clump, because of its increased area. In the end, too, such a clump will last longer without disturbance, because of the greater spread and liberty of the crowns. You ought to plant your Tiger Lilies as soon as you can get the bulbs. See article and illustrations in the present issue.

Begonia semperflorens (P. B. S.).—To keep your *Begonia* through the winter they should be lifted as soon as possible, potted in some good soil, such as equal parts of loam and leaf-mould, with a little sand. The pots should be just large enough to take the roots comfortably and no more, for a large mass of soil is not needed. When potted, place in a good light position in the greenhouse, and give water enough to keep the soil fairly moist, but avoid too much moisture. As the roots become active they may be kept somewhat drier, and throughout the winter only water enough to keep the soil slightly moist should be given. A minimum temperature of 45 degs., rising 10 degs. or 15 degs. during the day, is very suitable for the *Begonia*. With regard to its propagation, the plants that are kept over the winter will, on the return of warmer weather, push forth new shoots, which, when from 3 to 4 inches long, can be taken as cuttings. If obliged into pots of sandy soil and kept in a close propagating-case, they root as readily as a *Verbena*. If you had taken cuttings of your plants about a month or six weeks ago, they would be well rooted by now, and would stand the winter better than old plants. Another way of increasing this *Begonia* is by seed. By sowing a pinch of seed in gentle heat about the end of February, a good stock can be raised before bedding-out time.

TIGERS AND SHRUBS.

Propagating Lavender (*Cosmopolitan*).—It is not at all difficult to propagate *Lavender* if a few pieces or branches be pulled off from old plants and set in the ground to one third their depth. You can do this in the autumn or early winter.

Hydrangea paniculata grandiflora (C. P. W.).—There are few finer autumn-blooming plants than this. It must have a good soil, and be well manured with manure in the winter. Cut it down hard next spring to within three or four eyes of the base, leaving only the strongest growth. Water well during the summer.

Shrubs for border (*John H. Galsford*).—The following shrubs should suit your purpose.—Evergreens: *Berberis Aquifolium*, whose deep green divided leaves and golden blossoms are very pretty in early spring; *Berberis Darwini*, orange-yellow, flowers in May; *Cerasus Lauro-cerasus rotundifolia*, the neatest form of the common Laurel, which, though evergreen in many gardens, is, for all that, a valuable evergreen; *Euonymus japonicus*, a well-known shrub that will succeed under various conditions. *Ligustrum ovalifolium* (oval-leaved Privet) and its golden-leaved form (*elegantissimum*) will hold their own almost anywhere; *Osmanthus ilicifolia*, a Holly-like shrub; and the Holly itself. *Deciduous*: *Berberis vulgaris* (common *Berberis*); *Deutzia crenata* (large-pleated pretty pinkish flowers in June); *Philadelphus coronarius* (Mock Orange) and the smaller variety (*plumifolius*); *Philadelphus Cotinus* (Wig. plant or Smoky Bush); *Ribes* (Golden-flowered Currant) and *Ribes sanguineum* (Flowering Currant); *Spiraea arguta*, white; *Spiraea callosa*, red; and *Spiraea prunifolia* (flower-pleno, white); *Symphoricarpos racemosus* (Snowberry), whose large white berries form such a notable autumn feature; *Viburnum plicatum* (Japanese Snowball-tree); and *Weigela* (of sorts). Some of the above will, under ordinary conditions, exceed the height given, but, at the same time, they may be readily kept down to the required limit.

(Golden-flowered Currant) and *Ribes sanguineum* (Flowering Currant); *Spiraea arguta*, white; *Spiraea callosa*, red; and *Spiraea prunifolia* (flower-pleno, white); *Symphoricarpos racemosus* (Snowberry), whose large white berries form such a notable autumn feature; *Viburnum plicatum* (Japanese Snowball-tree); and *Weigela* (of sorts). Some of the above will, under ordinary conditions, exceed the height given, but, at the same time, they may be readily kept down to the required limit.

VEGETABLES.

Celery running to seed (*Mrs. S. Adkins*).—Celery, if sown very early and planted out, invariably bolts. If seed be sown about May—always soon enough for all ordinary purposes—the plants will not then bolt. Much, too, depends on how the young plants are treated, as, if allowed to become thick, starved, and weak in the pots or pans, the plants will often bolt or run to seed. Celery is a cross-feeding plant, and you cannot well have the ground too rich for it.

FRUIT.

Pears cracking (Anon).—Cracking of the fruit is invariably due to its getting into poor soil. Possibly your trees are worked on the Pear-stock, whilst your other trees are on Quince-stocks, and root shallow. Pear-cracking is caused by the fungus *Cladosporium*, but that would do no harm were the roots in good soil and kept nearer the surface. Grapes crack from drier causes. Roots too deep and in poor soil. They should be lifted and replanted shallow, good fresh soil being added. There has been great deficiency of sunshine this season, and the skins of the berries thin in consequence. Where borders are outside, roots at times have been heavily attacked. Muscat of Alexandria needs ample heat and sunshine.

Espalier Apples (*Thor*).—We do not know to what fruit catalogues you refer as being unable to find espalier-trained Apples there in them. Cordun trees generally have but one stem trained upright against a wall or fence, or else laid rather slantingly or in a horizontal position near the ground. Espalier trees have a centre stem erect, from which several branches radiate on either side horizontally. We think espalier trees admirable in any garden, and they are being more largely planted in this country. For large, keeping, later one is *Lane's Prince Albert*. A good Russet is *Brownlee's* or *Karamont*, both being good. A good early summer variety is *Irish Peach*, still one of the best for eating, and two good dessert varieties are *Allington Pippin* and *Ox's Orange Pippin*. These have fine flavour, and are handsome but not highly coloured.

Pruning Williams' Bon Chretien Pear (*W. H. Manning*).—As your standard Williams' Pear-tree, evidently some seven or eight years old, and, according to your sketch, 12 feet in height, was planted where it now is last November, the cause of its having thrown so few leaves is that the head was left unpruned when planted. That was a great mistake, as the few roots could not furnish sap to so large a head. Your best course shortly will be to shorten back from one-third to one-half all the leading branches, so as to greatly relieve the head, and thus enable the roots to furnish leaves next year. It there be any shoots that cross each other or grow inwards, cut those out. Then you must help the tree roots by placing over them a mat of long manure at once to wash in, and removing it in April to allow the spring to wash the soil. Replace with a fresh mulch 3 inches thick early in June, also in hot, dry weather give occasional soakings of water.

Planting garden walls (E. A. R. W.).—You may plant on east and west walls Pears and Plums, such Pears as Clapp's Favourite, Marie Louise, Louise Bonne, and Winter Nellis, and such Plums as *Czar*, *Victoria*, and *Monarch* for cooking, and *Transparent Gage*, *Jefferson*, and *Bralley's Gage* for dessert. On a north wall plant *Marble Cherries*. They do well there. The trees should be fully 10 feet apart, and if 12 feet, better still. On the south side of the house plant a *Moorpark Apricot*, an *Erlage Nectarine*, and a *Royal George Peach*, if there be room. Apple-trees in the vegetable garden should be in bush form on the Paradise-stock, and be planted either 4 feet from the paths, or else in rows across the quarters here and there. The trees should be 10 feet apart. Good varieties are *Loni Grosvenor*, *Pott's Seedling*, *Stirling Castle*, *Bismarck*, and *Lane's Prince Albert* of cookers, and *Irish Peach*, *King of the Pippins*, *Ox's Orange Pippin*, and *Sturmer Pippin* of dessert varieties.

SHORT REPLIES.

H. J. Guest.—No, the connection with the boiler must be from the top, otherwise there will be no circulation.
Rita.—We would advise you to relay the Box, following the directions we have given *Mrs. Walton*, p. 425.
Midland.—A good dressing of cow-manure dug in between the lines will be as good as anything you can apply.
Cosmopolitan.—You give us no idea as to your knowledge of the business, and without this, now-a-days, when there is so much co-operation, it is very difficult to realise any profit from growing plants in a small way, such as you suggest.
Legatee.—Not a gardening paper.
Woodward.—No, the *Malmesbury Carnations* are not suited for outdoor culture.
Miz.—If your Ferns are wooded, species no heat is necessary; if such as *Adiantum*, etc., then heat is required.
Constant Reader.—We suppose you mean the Willesden Paper and Canvas Works, Ltd., Willesden Junction, London, N.W.
Veritas.—We doubt very much whether you will be able to keep them. You might, however, try them in a room in the house, keeping them as near the light as you can, and not watering much.
J. H. W. Thomas.—You cannot do better than get "Hotday's Villa Gardening," from this office, price 6s. 6d., post free.
Inselm.—We know of no book dealing with manures for individual kinds of vegetables. You can never be wrong in using good cow or horse-manure in the garden, the former if your land is light, the other sowing best in heavy soils.
Arctic.—A. and B. Your best plan will be to use N.L. All, which is quite safe.
C. English Flower Garden—from this office, price 15s. 6d., post free.
Knutsford.—Mulch between the rows only, and close up and around the Strawberry plants.
Argyle.—1, Excavate the soil for the front path, and have two or three steps by which you can get round the back. No, do not use the frozen glass, as it darkens

the house too much, more especially for Tomatoes. Paint the trellis and the Roses will do all right. It is the acid from the galvanised wire that is the cause of the mischief.
Begonia.—A malformation and of no value.—*A. B.*
 If your Apple-tree has been planted as you say for ten years, it may be very doubtful if you will succeed in moving it. Better move the knees to another part of the garden.
Royal Siren.—See reply to "Hibernia," in our issue of Oct. 4, p. 407, re "Treatment of Hydrangea."
M. A. Harrison.—You say nothing as to your knowledge of the business, and there are so many things to consider that it is hard to say. Some good gardeners with business qualifications make a fair profit from such work, but the competition now-a-days is very great and poor prices are often obtained.
Winchester.—You must lift your Dahlias. See reply to "Flora," in our issue of Oct. 4, p. 418, re "Storing Dahlias."
E. A. R. W.—We should think that any of the climbing Roses would do well. Any of the Clematis family ought also to do well in such a position. Your only plan is to destroy the Hollyhock and start with a clean stock.—*An Old Reader*.—Your plan may appear to have suffered from mildew at some time, this no doubt causing the trouble. Have you had any rust on any of the plants?—*Dulcanarra*.—See article on "Autumn-flowering Roses," in our issue of Oct. 4, p. 418.—*Hartus*.—Yes, see reply to *Mrs. Walton*, p. 425, re "Lifting Box."
Tom.—See article in our issue of Aug. 11, p. 320, re "Plants for Cold Greenhouse in Winter." Yes, a Vine will do quite well in a cold-house—that is if you make a proper border.—*A Constant Reader*.—From the sample of bark you send, we fear that the tree will not recover. The tree was too large to move unless carefully done, and it would have been far better to have put in quite a young plant, which would have soon got established.
Brewood.—The two Pears you mention are both late, so you will have to put them on the market well you have, more especially in your district.—*John*.—We could find no insects on the Rose shoot you send. Your best way will be to cut out all the old and exhausted wood, and encourage new growth from the bottom.—*R. E. C.*—See article "Notes from a Rock Garden," in our issue of Sept. 6. You might grow *Arabis alpina*, *Aubrietia*, *Cerastium*, *Iberis*, *Myosotis*, *Phlox*, *Sisylia*, *Viola*, and many other things of a like nature.—*Thomas Hooper*.—It is impossible to suggest any means without further particulars as to treatment, etc.

NAMES OF PLANTS AND FRUIT.

*. Any communications respecting plants or fruit sent to name should always accompany the parcel, which should be addressed to the Editor of GARDENING ILLUSTRATED, 17, Farnival-street, Holborn, London, E.C. A number should also be firmly affixed to each specimen of flowers or fruit sent for naming. No more than four kinds of fruits or flowers for naming should be sent at one time.

Names of plants.—*Constant Reader*.—1, *W.* cannot name *Horista* flowers; 2, *Burbeckia hirta*; 3, *Golden Rod* (*Solidago Virgaurea*); 4, *Campanula*.—Quite impossible to say without seeing the flowers.—*E. B. W.*—*Fuchsia* Phenomenal.—*J. G.*—1, *Asplenium major*; 2, *Cornifolia varia*—*P. Shelley*.—*Asplenium latifolium*, *Miss Robinson*.—Specimen insufficient.—*G. G. Cook*.—1, *Aster ericoides*; 2, *Rudbeckia hirta*; 3, *Coreopsis tinctoria*. In sending specimens for name it is advisable to write the number on the outside of the paper enclosing the flowers.—*L. T.*—*Asparagus delavayi*.—*Henley*.—*Chrysanthemum maximum*.—*Ernest Ballard*.—1, *Crucianella pubescens*; 2, *Dianthus hybrid* form; 3 and 4, *Forms of Cyclamen europaeum*; 5, *Sisyrinchium striatum*.—*R. Greening*.—1, *Going out of bloom*, *Solidago Virgaurea*; the other, *S. canadensis*.—*Puzzled*.—Please send flowers.—*Holly*.—1 and 2, *Varieties of Clematis lanuginosa*. Remove the weak and overcrowded branches in February or March. 3, specimen insufficient.—*T. B. Burton*.—Rose had fallen to pieces but it is evidently *Réve d'Or*.—*E. J. M.*—*Abrotanum* elegans.—*A. M.*—*Aster Amellius hessarianus*.—*E. J. M.*—*Campanula celestis*.—*G. R. Parrell*.—*Althea Armeria*.—*A. W.*—*Recallonia sp.*, and 1 flower.—*G. M. S.*—*Caryopteris mastacanthus*.—*J. Hillier*.—*Retinospora pisifera aurea*. Yes, you can train it in doing this early in the spring.—*Monitor*.—Rose like *Maria Henrietta*.

Names of fruit.—*J. M.*—*Plum Kirke's*.—*W. L.*—1, *Grosse Mignonne*; 2, *Crimson Calande*. It is very difficult to name *Peaches* without seeing the young wood.—*Anon*.—1, *Tower of Glamis*; 2, *Yorkshire Breeding*; 3, *Small Emperor Alexander*.—*E. A. Langrish*.—*Apple* Waltham Abbey Seedling.—*Miss Thomas*.—*Apple No. 6*, *Loebach* of Oldenburg.—*John H. Trean*.—1, *Apple Warner's King*; 2, *Not recognised*.—*L. A.*—1, *Deux Sœurs*.—*Bateman, Mon.*—1, *Devonshire squar-den*; 2, *Boston Russet*; 3, *Beauty of Kent*; 4, *Beauty of Kent*; 5, *Local variety*; 6, *Cornish Aromatic*.—*E. S. Singlewell*.—1, *Beurre d'Amisais*; 2, *Emile d'Alençon*; 3, *Beurre Hardy*; 4, *Heliotte Panda*.—*R. M. W.*—*Humelov's Seedling*; 2, *Whittington Favourite*; 3, *Challe's Kernel*; 4, *Beauty of Kent*.—*Brewood*.—Quite impossible to say unless you can send us samples of the Apple you refer to.

Catalogues received.—*Haage and Schmidt, Erfurt*.—*Novelties of Seeds for 1903*.—The Four Oaks Nursery and Garden Sundries Co., Sutton Coldfield, Birmingham.—*Illustrated Price List of Underdale Nurseries*.—*Henry A. Drees*, 114, Chestnut-street, Philadelphia.—*Arthur H. Sargent*, 17, Wm. Sydney-street, Tanworth.—*Roses and List of Carnations and Pinks*.—*E. P. Dixon and Sons*, Hull.—*List of Fruit-trees*, *Roses*, etc.

Lavender culture.—Will any reader of GARDENING ILLUSTRATED inform me where I can purchase, and at what price, a reliable treatise or book on the "Cultivation of Lavender," including the harvesting of the crop and the distillation for the oil and for Lavender-water, with information where the necessary distilling apparatus can be obtained, and price of same? Information also asked as to the most suitable soil for Lavender, and whether the Australian climate would be too warm for its successful culture.—SOUTHERN CROSS.

PLANTS AND FLOWERS.

OUTDOOR PLANTS.

THE WILD BOG GARDEN.

SOME twelve or fifteen years ago in a corner of the grounds at Wolsey was an untidy swamp, a disused pond, about a third of an acre in extent, surrounded by high banks, and beyond these by lofty trees and a few shrubs. The middle part was a regular swamp, overgrown with tall Nettles and common Sedges. In my childhood I can remember it used to be called the "Wilderness," and in the lofty Elms was a strong colony of rooks; these, alas! have long since forsaken the spot. Many were the suggestions for converting this untidy spot into something more beautiful. Some suggested a rock garden, but there was too much shade; others the remaking of the pond, but there was already quite enough water about the place, the River Trent flowing within a few yards of the house, and there being another fish pond close to it. At last I happened to come across "The Wild Garden," and after reading therein the charming descriptions of plants naturalised by brookside and in the bog garden, I formed the idea of converting this wilderness into a semi-wild bog garden.

The first thing was to cut a winding ditch through the centre of the bog, and this has ever since been a running stream, bordered with Ferns and other plants, and another ditch round the outside of the swamp to drain it, with a rough pathway all round and one skirting the stream through the centre, and to construct some rustic wooden bridges over the ditches. Then I planted several good clumps of Rhododendrons, a fair-sized clump of scarlet Dogwood, a few clusters of hardy Bamboos, and a few shrubby Spiraeas. I also planted with Azaleas a good-sized mound, raised from the soil out of the ditches. These formed the foundation for my bog garden, and between these clumps and on each side of the ditches I planted numerous patches of herbaceous and bog plants. Many of the former were obtained from the thinning out of the herbaceous border, and many more of both these and the latter were procured from the different woods and swamps about, such as Ferns, the brilliant Marsh Marigold, the common yellow Flags, Meadow Sweet, Loosestrife, some of the prettiest of the Sedges and Reeds, and many others. Then in the autumn I purchased several thousand bulbs, the banks being planted with Snowdrops, Winter Aconites, Snowflakes, Crocuses, Bluebells, Grape Hyacinths, Scillas, etc., whilst the sides of all the ditches were planted with Daffodils and Turk's-cap Lilies. In the north-eastern corner, from which one enters into the bog garden, I made a rough rock garden, and this is covered with various kinds of Ferns, and here the Oak and Beech Ferns flourish and seem really "at home," as also the Hart's-tongue and several other species.

Of course, as I put in all sorts of plants and bulbs at first, regardless of their suitability for

the situation, I had many failures and many died, but quite enough survived to encourage me to persevere, and gradually the untidy swamp assumed an appearance of beauty; and possibly now many would consider the bog garden the most interesting and beautiful part of the gardens. Many a plant which I have tried in vain to grow in the ordinary herbaceous garden here not only lives, but flourishes with scarcely any care. Phloxes, Delphiniums, Monk's-hoods, Asters, Day Lilies, Plantain Lilies, Torch Lilies, and, above all, the Trilliums or Wood Lilies, the Evening and other Primroses, all flourish here; nor must I forget the Japanese Iris, or Iris Kämpferi, which also does exceedingly well. Early in February, just as the snow disappears, some of the banks are clothed in white by the Snowdrops, with here and there a bright patch of Winter Aconite. Then, following these, the other banks break out into a mass of various colours as the Crocuses appear, and these, again, are succeeded by a mass of blue from the wild and Grape Hyacinths. Later on clumps of Tiger and Orange Lilies appear on these banks, then all along the ditches and other parts of the bog garden appear rows and groups of yellow Daffodils, followed by the Jonquils and Pheasant's-eye Narcissi. In other parts are groups of Primulas, Cowslips, Tulips, and the brilliant-coloured Marsh Marigold. Then one of the most successful effects is when the mass of Primula japonica comes into bloom, this plant growing like a common weed with flower-stalks 2½ feet high, and seeding itself in all directions, whilst amongst the scarlet Dogwood the ground is covered with the pretty little pink Claytonia, with here and there clumps of the graceful Solomon's Seal. The Ferns also luxuriate in the boggy, peaty soil; the common Lady Fern grows to a gigantic size, the Osmundas also, and the Onocleas, but, towering above all, the Ostrich-feather Fern (Struthiopteris germanica) here attains the extraordinary height of over 6 feet. In July, amongst the Ferns, and in large groups near them, appear gigantic white and spotted Foxgloves, forming, perhaps, one of the most striking effects of all. Then come the graceful feathery Spiraeas, the most beautiful of which to my mind is the crimson Spiraea palmata, which grows luxuriantly here. I must not omit to mention here the Californian Saxifraga peltata, which lines one of the ditches in front of the Ferns, and grows nearly 5 feet high, with its broad, tropical-looking leaves. I had great difficulty in establishing the Gunneras, but have succeeded at last, and they form quite a picture by the side of the stream in front of a tall group of Bamboos. In August some fine clumps of Phloxes and the Golden Rods produce some bright colouring, and finally, in September and October, appear the Torch Lilies, and some grand groups of Asters to finish up with.

Almost every week the picture changes, and for ten months in the year some part is bright and gay with flowers, and, even in December and January, the scarlet-barked Dogwood gives a bright and cheery effect, contrasting with the dark green Rhododendron clumps. This garden is a source of continuous amusement and occu-

pation to me, and, as I not only planned and constructed the whole, but also do all the work of replanting and weeding myself, I look upon it far more than any other part of the gardens as especially my own garden.

Wolsey, Stafford.

C. M. WILSELEY.

PLANTING NORTH BORDER.

I wish to plant a border against a house wall, aspect north. Would Day Lilies, Monarda, Tritoma, etc., be suitable? I want a late summer and autumn effect, and a good deal of strong colour. Are there any Lilies which would flourish in such a situation? Kindly advise as to suitable plants.—E. M.

[You do not tell us the width of the border, and we run the risk of suggesting unsuitable things. We take it you can enrich the border in question, and otherwise prepare it by deep digging and the like. Of the plants mentioned below, the average height is given that you may discard any that would be unsuitable. We would not include Day Lilies in this border, but Monarda and Tritomas certainly as among the finest of late summer flowers. The former are not usually more than 3 feet high, but the Tritomas, which were fully described and figured in a recent issue, vary from 3½ feet to 6 feet, or even more. Anemone japonica, in white, red, and pink, is excellent, growing 4 feet high, and flowering profusely. Galtonia candicans, large white bells, 3½ feet; Stenactis speciosa, blue-mauve, 2½ feet; Gaillardia in variety, 2½ feet to 3½ feet, and very showy; Eryngium amethystinum, 3 feet; Echinops ruthenicus, 3 feet; Rudbeckia Newmanii, 2 feet; R. purpurea (Winchmore Hill variety), 4 feet; Harpalium rigidum, H. r. præcox, both 3 feet; such Helianthus as H. multiflorus, H. m. plicatus, H. m. Soleil d'Or, all about 4 feet high; Scabiosa caucasica and S. e. alba, 3 feet; Veronica longifolia subsessilis, fine blue, 2½ feet, a grand plant for massing; and equally good Aster Amellus, A. acris, A. leucogentis, A. densus, 2 feet; A. N. A. ruber, A. N. A. Melpomene, and A. N. A. Mrs. Raynor, 4 feet, are showy and well suited to effective grouping generally. The following Lilliums could also be planted: L. tigrinum and its varieties splendens, Fortuncii, and fl. pl.; L. speciosum album, L. s. rubrum, L. s. Melpomene, L. chalcidonicum, etc. You may with advantage also plant the seedling hybrids of Gladiolus gamlavensis, G. Childs, or G. Lemoine, the two latter sorts being much harder than the first-named, and containing some really remarkable as well as novel shades of colour. Apart from the above, there still remains quite a host of good things in herbaceous Phloxes.]

Calystegia pubescens fl. pl.—I have never known this pretty trailer flower so profusely as it has done this season, which fact is the more remarkable as the summer has not been a particularly bright one. Some of the trails are quite 9 feet in length, and have been clothed, as they grew, with an abundance of pretty pale rose blossoms which are always so much admired. It is of easy culture and is useful for training on fences, arbours, verandahs, and similar places for creating a summer display.—W. V.

THE KNOTWEEDS (POLYGONUMS).

Now that beauty of form is appreciated, many plants of graceful habit that were formerly discarded as worthless, either on account of

rather slender, but well furnished with stem-clasping leaves, with deeply veined surfaces and tapering points. Its slender flower-spikes, which rise a foot or more above the main body of the foliage, are crimson. A variety of this

green leaves, with a dark blotch in the centre of each, and numerous heads of pink flowers. When once established in light warm soils, it appears every year from self-sown seeds. Its neat habit and the delicacy of its flowers are attractive.

P. CUSPIDATUM is a plant of sterling merit, now common. Its shoots are speckled with purple; its broadly-ovate leaves, which are of a dark dull green, are frequently variegated with faint silvery blotches, and its creamy-white flowers are borne in profusion. Its stately habit of growth, combined with the luxuriance of its foliage, are attractions of no ordinary character. The best place for this plant is by the margin of water, in a shrubbery ditch, or any like place, as once in the flower-garden it is very hard to get it out.

P. ORIENTALE.—A tall, free-growing annual, reaching a height of 8 feet to 10 feet. Its stems are very robust, and it has slender spikes of crimson flowers, which continue until the frosts. To obtain a good development of its foliage, it should be grown as a single specimen and without shade to induce it to bloom freely, when it makes a fine ornament. There is a variety of this with white flowers, though rarely met with. It is a native of Northern India.

P. POLYSTACHYUM.—This forms a thicket of stout, erect stems, which root strongly from the first few joints above the ground. Its leaves, which are somewhat crowded, have a light-coloured under-surface. It reaches the height of 5 feet to 6 feet, including the flower-spikes, which are slender and greenish. The qualities that recommend it are its bold, erect habit, and dense, woolly foliage. It is a Himalayan species, flowers pure white, sweetly scented.

P. SACHALINENSE.—A native of the Island of Sachalin, and often attaining the height of 10 feet to 12 feet, with broadly-oblong leaves upwards of a foot in length, and of a bright green. Its flowers are rather inconspicuous, greenish-white, and disposed in slender drooping racemes. It luxuriates in a moist subsoil, near the margin of water, where it is very effective in company with grassy vegetation. It also makes a fine, bold feature.

Polygonum baldschuanicum.

their gross habit or inconspicuous flowers, get a place. Polygonums are of the easiest culture, thriving in any ordinary garden soil, but are greatly improved by cultivation. All those of a bushy habit should be so planted as to have a clear space all round, in order to give the foliage all the air and light possible, as overcrowding is frequently the cause of naked stems and a straggling habit, to remedy which tying-in has to be resorted to, which detracts much from their natural appearance, their beauty consisting in the innumerable flower-spikes rising above a gracefully developed mass of foliage continuous to the ground. Those of the *P. cuspidatum* type produce stems of sufficient strength to support their spreading crowns of foliage. The annuals, unless grown as single specimens, and in sheltered situations, will require support, and the dwarf perennials, most of which are evergreen, need very little attention beyond an occasional trimming. The stems of all the tall hardy species, being of annual duration, die off in the autumn, and, as the succeeding ones do not appear before April or May, this must be taken into consideration when planting for effect.

P. AMPLEXICAULIS.—This usually reaches the height of 4 feet to 5 feet. Its stem is

named oxyphyllum differs in having white flowers with conspicuous red anthers.

P. BALDSCHUANICUM.—This is one of the finest in the genus. Its chief claim to distinction is that it is a climber, coiling itself around any support that may be given it. In a few weeks and before it comes into bloom it will attain a height of from 12 feet to 18 feet, provided the supports are of sufficient length. The flowers are of a creamy-white and tinged with rosy pink. It is practically a deciduous climber, which in severe weather may be cut to the earth to break away freely in the spring again. In mild winters the twining stems also retain their vitality and send forth fresh growths in spring from axillary buds along the stem. Apart from its value as a climbing plant, the sprays of bloom are very useful for cutting. It commences to bloom about the end of June and continues flowering for several weeks.

P. BRUNONIS.—Of the known evergreen species this is probably the best. Its leaves, which have a white under surface, are so numerous as to form a dense cushion, from which arise the crimson spikes. It is a pretty border plant, and a native of the Himalayas.

P. CAPITATUM.—This is a charming little annual of a spreading habit, with oval greyish

P. vacinifolium.

either planted on the turf or in a good position where it can develop its noble proportions; but it is too rank for the flower garden.

P. VACINIFOLIUM.—Few plants surpass this for rock work. It differs widely from all its

congeners at present in cultivation, unless *P. crispum*, which resembles it in its twiggy habit. It is quite hardy, and thrives in almost any moist soil, and is seen to the best advantage where its shoots can ramble over stones or tree-stumps. Under favourable

of garden one may see the natural form of a plant, whereas with perhaps a hundred little bunches of the same length on the same plane it is impossible.

The Society itself might do something to prevent such "exhibitions," as it is in its

seedlings with a firm hand, and in spring sow the patches rather thickly with Grass seed and white Clover. By a rather free sowing of the Clover its quick growth should overcome the weed in question. It is quite possible the latter has been introduced with the soil which you have used as a top-dressing. Generally, however, the Clover is strong enough to overcome ordinary weeds, and the same applies to the Daisies of which you speak. A perfect lawn requires much attention before it is perfect.

Hedgehogs in gardens.—I have always heard that hedgehogs are useful animals in gardens, but for some time past a hedgehog that has his home in my garden has been in the habit of coming out every night, and has studded my lawn with holes about an inch in diameter and 2 inches in depth. I do not want to drive him out if he is useful, but I do not want any more holes. Can you advise me in the matter, and suggest to me what he is looking for and what I ought to do?—INOLKNOOK.

[Hedgehogs are, as a rule, useful creatures in gardens, as they feed on insects, slugs, and worms. Their diet is, however, very varied, as they do not despise small animals, birds' eggs, snakes, roots, and fruit. I imagine that your visitor makes the holes in your lawn in search of grubs or other insects, or perhaps there is some weed growing on the lawn to the roots of which it is particularly partial. I can suggest no other reason, and while it is free to roam over the lawn I do not see what can be done to prevent it from grubbing about.—(C. S. S.)]

Spring gardening.—Where beds have been occupied with summer subjects, there is nothing to be gained by keeping the plants therein any longer, as by this time they present a worn-out and bettered appearance. If it is not intended to supersede them by other plants for spring blooming, it is, at any rate, desirable that an early clearance should be made. Now is the time to remove into their final quarters Wallflowers, Daisies, Forget-me-nots, Primroses, Aubrietias, etc. Tufted Pansies also make a brave show in spring, and, if planted on a warm border, will blossom in company with Hyacinths and Tulips. Cuttings of Tufted Pansies, struck a few weeks ago, may be safely removed to a sheltered border.—LEAHURST.

Aubrietias.—The past season has suited rock plants like Aubrietias admirably, as there has been no long spell of drought to burn them up. Even in a dry summer it is wonderful how quickly these old flowering plants pick up in the autumn, and, when the first spring sunshine has come, they are all aflame. It seems unnecessary, therefore, to recommend any particular culture for the Rock Cresses when they will grow almost anywhere; but, if I had to plant this autumn, I would, if possible, give

The great Japanese Knotweed (*P. cuspidatum*) by water.

conditions it grows rapidly, and produces its Whortleberry-like leaves and rosy flower-spikes in profusion. This is also a native of the Himalayas.

HARDY FLOWERS AT THE DRILL HALL.

The way in which many beautiful plants now in bloom were shown by the nurserymen at the last Horticultural Society's meeting was far from one to show their beauty fairly. The plants were jumbled together like so much hay, and no attempt was made to separate the good things, or to take care of the colours. Flowers were picked up and squashed together and all shown on the same level, the natural forms of plants being by this means suppressed. Amongst the worst cases was Mr. Forbes, of Hawick, who showed a number of seedling *Phloxes* in the poorest and worst colours, and Mr. Ladhams, of Southampton, had excellent hardy plants, but packed together so that the eye could not separate them. Messrs. Barr were nearly as bad. If these gentlemen and all like them cannot see their own way to better effect, they would do well to employ some of the young ladies in the London flower shops.

On the other hand, outdoor Chrysanthemums gathered in the open air were arranged very well by Mr. Wells, of Redhill. Some attempt was made to get a little variety, light and shade, into the group, and the colours were very nicely kept.

In addition to bad arrangements there is also bad choice. For example, Messrs. Barr showed an immense number of Michaelmas Daisies, and about six of these would have been better than the whole lot, each of the six shown rightly, with its natural form and a little "air" about it.

Some of the so-called new kinds of Michaelmas Daisies are very poor. We have now so many beautiful hardy flowers that it is a pity to show (in an exhibition, too!) plants of quite inferior merit, poor in colour, and often poor in form. It may be said that it is a question of taste, which it is not the nurseryman's business to supply. But two things that would help a good deal might easily be done; that is, leave out weedy sorts and bad colours. We are not asking for anything but what is reasonable, as in nature and in even the worst kind

interest as well as that of the public that the plants should be seen with their true and natural effect at the meetings.

NOTES AND REPLIES.

Lawn weed (C. H. W.).—We received the sample of the weed, crushed beyond recognition. We can only suggest that the weed is in all probability an annual and of a very free-seeding type. If we are correct, it will be more easy to get rid of it by keeping watch over its flowering, and thus prevent any of the plants seeding. What you send appear small seedlings that have germinated in late summer from seeds probably ripened about June. It may be a species of *Polygonum*, but we cannot

P. polystachyum.

be sure. To get rid of it, it would be best to dig out the seedlings and burn them. As a further precaution you might take out some of the soil, though we do not advise this unless the pest is very bad. Anyway, clear out the

them the benefit of cool niches and ledges of limestone and sandstone, of which my rockery is composed. If variety is wanted, then Royal Purple, Fire King (crimson), and Souv. de W. Ingram (rose) might be tried.—W. F. D.

ROSES.

SOME NEW ROSES.

As I was this year unable to attend the summer shows of the N.R.S., I shall be greatly obliged if you can give, as on previous occasions, a list of new Roses for 1901 and 1902, with notes thereon. I do not know if such a list has been recently published. If so, I fear I have missed it.—FRANK THOMAS, *Kingston-on-Thames*.

[There was nothing very startling exhibited at the Temple Show of the National Rose Society this year, excepting Mildred Grant. Those who saw the bloom that received a special medal as the best Hybrid Tea in the show can safely say they never saw a finer flower. Of Roses not yet in commerce I thought well of Princess Victoria, although perhaps rather too near Viscountess Folkestone; and Dr. Campbell Hall, something after La Fraicheur. Sir Robert Stout resembles Charles Lefebvre, and will be very welcome, for we want dark Roses, and if they are Hybrid Teas so much the better. There was also shown a white sport from Lawrence Allen, which should be valuable if it retains the good form of its parent. Somehow the boxes of new Roses usually seen at shows cut a sorry figure, and they often libel a Rose, for how can one obtain a good bloom from a plant perhaps weakened through propagating. Many Roses are now introduced which, taken as individual flowers, fall short of the exhibitor's ideal, but the profusion of bloom and their late-flowering character give them a value which all who desire their gardens to be gay in autumn are ready to admit. Taking the varieties alphabetically, my first is

ALICE LINDBELL (H.T.), a gold medal Rose having creamy-white flowers with pink centre, petals of great substance.

BEN CANT (H.P.).—A grand flower, colour deep crimson with dark flushes in the centre. It is of the Victor Hugo type, being a cross between that variety and Suzanne M. Rodocanachi. It is very sweet, very perpetual, and a good grower.

BOADICEA (Tea-scented).—In colour pale peach with rich pink shading. The flowers are high centred, petals large and stiff. It is somewhat after the style of Mme. de Watteville, but a deeper and really handsomer flower. It is sweet-scented and a strong, vigorous grower.

DOROTHY PERKINS.—A hybrid of that interesting Rose K. Wichuriana, and from its exquisitely-formed blossoms in huge panicles and lovely pink colour will be valuable as a pillar Rose. Unlike the type this Rose grows erect in the way of Crimson Rambler, and will be a useful companion to it.

DR. FELIX GUYON.—A Tea Rose of charming form, orange in colour with apricot shading, very double, will make a good show bloom.

DUCHESS OF PORTLAND (Hybrid Tea).—Rather too near Kaiserin Augusta Victoria—in fact, it seems a glorified form of that grand Rose.

FRAU KARL DRUSCHKI (H.P.).—Snowy white, deep conical buds of splendid appearance. Open flowers are large, not too double, consequently expand freely.

FUSION.—This is a seedling from Mme. Eugene Verdier, but more vigorous, consequently will make a good wall Rosa. Colour deep chamois-yellow.

LADY BATTERSEA (H.T.).—This, a cross between Mrs. W. J. Grant and Mme. Abel Chatenay, has a finely-formed bud, but the open flowers are rather disappointing. Colour cherry-red, tinted orange.

LADY MORA BRACLERG (H.T.).—A valuable forcing and show Rosa, rich madder pink. Very distinct, free-blooming and free-growing.

LADY ROBERTS.—A charming and highly-coloured sport from Anna Ollivier. Colour rich apricot with coppery-red base to petals.

MME. ANTOINE MARI (Tea-scented).—One of the prettiest new Roses I have seen for a long time, the buds are so perfectly moulded and the colour rose washed and shaded white, being most attractive. The open flowers are nearly as large as those of G. Nabonnand.

MME. C. MONNER.—A semi-climbing Hybrid Tea of great merit. Flowers rosy-flesh, centre yellow with salmon and orange shading. Like many of the Hybrid Teas, in autumn or when forced, the flowers come almost entirely orange-yellow.

MME. JEAN DUPUY.—This Tea will, I think, become as popular as Mme. Lambert. The colour is a reddish-yellow in centre, outer petals suffused with rose-pink. The growth, too, is vigorous.

MME. MARIE CROIBIER may be described as a deeply-coloured Caroline Testout. This, with the type and the white sport Admiral Dewey, should make a charming trio.

MME. VERMOREL (Tea-scented) is one of the best Teas we have had for some time. It opens well outdoors, and the blossoms are of great substance. Colour coppery-yellow with rose shading. It is a good grower.

MAMIE (H.T.).—A little wanting in brightness, otherwise a beautiful shapely bloom of great depth. A fine grower, colour rosy-carmine with yellowish base.

MERCKES.—A soft rosy-pink coloured Rugosa Rose, as lovely in form as a Tea Rose, and the colour equally as delicate.

MILDRED GRANT (H.T.).—A noble flower for the show board, but I should prefer to test it further in the open before pronouncing an opinion as to its merits in the garden. The colour is blush-white, tinted pink. Enormous petals like large shells.

MORNING GLOW (Tea-scented), rosy-crimson, shaded orange and fawn, is a splendid grower, and will be much sought after for its colour. It is also of large size.

NOELLE NABONNAND.—A climbing Hybrid Tea, even more vigorous than Reine Marie Henriette. It is a fine semi-double flower of the Barlow Job type, colour velvety-crimson, shaded violet.

PAULINE BENSEN (H.T.).—Creamy-white with yellow centre, fine buds, good grower, very promising.

PEACE.—A white-flowered sport of G. Nabonnand, possessing the fine characteristics of this excellent Rose.

PERLE VON GODESBERG (H.T.).—A sport from Kaiserin Augusta Victoria, colour golden-yellow. I believe this Rose will be much wanted, but should prefer to see a little more of it before giving a definite opinion.

PRINCE DE BELGIQUE (H.T.).—Colour silvery-flesh with salmon shading.

QUEEN ALEXANDRA.—A rambler Rose that has given much satisfaction. Its colour is rich rose-pink. Fine trusses like Crimson Rambler, and equally free in growth.

ROBERT SCOTT (H.T.).—This looks like a glorified Comtesse de Serceny, and its fine bold flowers are useful either for show or cutting. The growth is somewhat stumpy, as one might expect from a cross between Merveille de Lyon and Mrs. W. J. Grant.

SOLEIL D'OR.—This fine break will be in demand presently. It is a fine garden Rose, and blooms freely in autumn. It is a hardy kind, and will be useful for its colour in districts where it is not safe to grow the Tea Roses.

SOUVENIR DE PIERRE NOTTING.—I expected to see a grand flower from a cross between Marsechal Niel and Maman Cochet, but as seen up to the present I cannot say much for it.—ROSA.]

NOTES AND REPLIES.

Roses for low wall.—Will you kindly give me the names of six Roses suitable for a wall only 7 feet high, facing S.E., and well protected from E., soil good and deep? Would strong growers, such as Duke of Edinburgh, Charles Lefebvre, etc., do better than real climbers?—W. J. R.

[The strong-growing Hybrid Perpetuals you name would do well against this 7-foot wall. Another brilliant Rose would be Gruss an Teplitz. Three varieties of lighter shades we can recommend are: Gloire Lyonnaise, Marie Van Houtte, and Billiard et Barré.]

Roses in bad health.—I shall be obliged if you will kindly tell me in your next issue what the pests are that are on my Rose-trees in the greenhouse, and the best way to destroy them. I am sending you a few of the leaves with the insects on; they are very small. The trees are making a lot of new wood, but I cannot get clear of the pests.—YORKSHIREMAN.

[Your Roses have been badly attacked by thrips, and there is also some red-spider. For the thrips the best cure is to fumigate the house two or three nights in succession, or syringe the tree with a solution of Quassia-chips and soft-soap, while for the other, the best way is to syringe it freely with rain-water, if you can get it.]

Roses for arches.—In centre of wall garden there is a pond, four paths leading to it. I should like a wire arch at end of each path for Roses. How high should

they be, how wide, and what eight Roses would you suggest? A red, pink, yellow, and white I should like. It is a sheltered, sunny spot. I am anxious to make a good thing of it.—L. B. GAGE.

[The arches should be from 7 feet to 8 feet high. We have no fancy for the wirework arrangements usually erected, but would prefer an arch of stout iron about the thickness of gas piping. The arches may be made to span the path according to width of latter. You must trench the ground deeply and add some good farmyard-manure, but see that this be not brought into close contact with the roots when planting. Some of the best Roses for arches are summer-blooming only, but you could plant one of these and an autumnal bloomer against each arch, so that you obtain blossom late as well as early. We give you the names of eight of each. *Summer Bloomers*.—Red: Crimson Rambler, Amadis. Pink: Flora, Queen Alexandra. Yellow: Electra, Claire Jacquier. White: Felicite-Perpetue, Bennet's Seedling. *Autumnals*.—Red: Reine Marie Henriette, Longworth Rambler. Pink: Mme. Marie Lavallee, Climbing Captain Christy. Yellow: Gloire de Dijon, Mme. Berard. White: Mme. Alfred Carriere, Aimée Vibert. There is a climbing Moss Rose named Cumberland Belle which would do well for a pink summer-blooming variety.]

Climbing Roses on stable walls.—I have some old Rose-trees on walls in my stable yard. They have grown very tall and are rather bare at the base, but have an enormous growth at the top which hangs over. What ought I to do to them, and when ought they to be pruned? One did not flower at all this summer. Another is the white Cluster Rose, semi-double, small flowers with pink underneath—I think Felicite-Perpetue. It flowered splendidly, but all at the top.—HELVY.

[Many of the fast-growing Roses are inclined to this bareness at the base which you complain of. We should advise you to unfasten one or two of the main growths and retrain them to the wall in a zig-zag fashion. By so doing you encourage basal eyes to start into growth, and in a year or two there should be several young growths. Another plan is to cut down to the ground one of the oldest growths each year, but where there are only one or two such growths, then the former method is best. The Rose you describe is undoubtedly Felicite-Perpetue. There should be no difficulty in securing a bushy base to this Rose if you adopt one of the methods described above. The long growths at the top should be thinned out in March, shortening such of the others as are retained and that are extra long. By leaving them as long as is practicable the hush growths will be considerably assisted.]

Yellow climbing Roses for pillar.—Will you be kind enough to name in an early number of your valuable paper five climbing yellow Tea Roses of the same class, and, if possible, as free flowering and beautiful as Mme. Berard. I want to plant them in a border facing south, to be trained to strong stakes about 6 feet high, as I have no walls available. I have already Gloire de Dijon, Mme. Berard, and W. A. Richardson trained in this way, with good results. The soil is rich and manure plentiful. The climate here (Swansea Bay) is mild, and I have seldom seen snow and ice during the six years I have lived here. I had thought of including *Prie des Jardins*, but hardly enough for outside, and would also like your opinion of the Hybrid Tea Souvenir de Mme. Eugene Verdier. Is it a good grower and a free-flowering Rose?—GLAMORGAN.

[You should be able to succeed with yellow Roses, such as one could not advise for exposed and bleak situations. Your plan, too, of growing the vigorous Teas and Noisettes against poles has much to recommend it, for some of these Roses make most beautiful pillars. You might find climbing Perle des Jardins hardly enough in South Wales; if so, it would be a valuable kind, as plenty of handsome blossoms is produced. Five other good kinds would be: Duchesse d'Auerstedt, Billiard and Barré, Belle Lyonnaise, Mme. Moreau, and Réve d'Or. The variety Souvenir de Mme. Eugene Verdier is a Hybrid Tea of dwarf growth. Probably you refer to Mme. Eugene Verdier, a charming Tea Rose, rich orange and yellow in colour, but scarcely strong enough for a 6-foot pillar.]

Rose Countess of Oxford.—This Hybrid Perpetual is never seen better than it is in autumn, and, like its sport, Pride of Waltham, the very large flowers show up well on the plant. The colour of Countess of Oxford is bright carmine-red, a glowing tint, free from all suspicion of magenta or purple. The foliage is very showy, and in the wood the variety is very distinct, as not a thorn is to be seen. It can be propagated readily from cut-

tings, but the finest blooms are cut from plants on the seedling Brier. It is a pity such a gorgeous Rose has no fragrance, but it shares with the majority of the Victor Verdier race this distinction.—Rosa.

FRUIT.

APPLE BLENHEIM ORANGE.

PROBABLY no Apple is so popular as the Blenheim Orange. It is a large and handsome fruit of good quality and texture, and may be used either for cooking or for dessert about Christmas and the New Year—a period of the year when Apples are in great request. According to the Royal Horticultural Society's classification it is to be known as a dessert Apple, although full-grown specimens are beyond the size generally considered best for the dessert, but its very handsome proportions and appearance command admiration, and its flavour is

cankers badly, but this is generally when the soil has been over-matured at planting time, or where the staple is cold, wet, and undrained. Apply no manure of any kind to the soil when planting, but rely entirely on top-feeding. If the orchard is on Grass it is a good plan to clear away the rough Grass round the trees every winter as far as the feeding-roots go and apply a top-dressing in the early spring, adding, when the fruit has set and is beginning to swell, a further mulch of good cow-manure and watering freely if the weather is at all dry and the ground porous. Those who are not prepared to allow the trees of Blenheim Orange plenty of head-room had better leave this Apple out of their calculations when planting.

Like many other popular Apples, it is claimed for the Blenheim that there is more than one variety, and attempts have been made to describe them, but these so-called varieties of the Apple have turned out to be some totally distinct and generally inferior variety, though

in some cases stock influences have contributed to a slight change of form or colouring. We understand there is a form of this Apple grown in Gloucestershire which is called the "Green Blenheim," and about it we should be glad if any of our correspondents would send us some information. At the great Apple Conference at Chiswick in 1883, the best fruits of Blenheim were sent by Messrs. Jefferies and Son, of Oxford, and the true and best type is supposed to be mostly found in that neighbourhood, having been raised in a garden belonging to a baker at Old Woodstock, near Oxford. It is found under many names in various parts of the country, some of its synonyms being Beauty of Hauts, Droggo's Fame, Gloster Pippin, Northampton, Prince of Wales, and Ward's Pippin.

NOTES AND REPLIES.

Crop of Pears.—Mr. E. O. Hancock, of Warmminster, Wilts, has a pyramid Pear-tree in his garden at the present time (October 15th) on which are five distinct crops of fruit, ranging from full-sized, perfect specimens to those from which the blossom has only recently fallen. All are, for their age, perfect fruits of five distinct sizes. The season is too far advanced for more than two lots to ripen.—M. H. SMITH.

Strawberries for succession.—I should be much obliged if you would give the names of the best Strawberries for succession, in order to have pickings as early and as late as possible, with a good supply all through the season for home consumption.—THOMAS LUNAN.

[A good selection would be Vicomtesse H. de Thury, Royal Sovereign, Sir J. Paxton, Sir C. Napier, and Oxonian.]

Apple Blenheim Orange, said to be on own roots.

very pleasant if not over-piquant. As a cooking Apple, except for making whole, it seems to lack acidity, though this very fact commends it to many people. From the grower's point of view it is not always satisfactory for the tree, except when in bush form on the Paradise-stock, takes many years to come into bearing, and even when it has commenced to fruit it is by no means certain. As a close-pruned garden tree it is one of the worst of bearers, and in this form it is useless to plant it, because its nature of growth and fruit-bud formation make it imperative that to produce crops of fruit it shall be allowed freedom of growth. The most satisfactory trees are those planted in cultivated orchards where they are allowed to spread themselves without limit in bush form and pruned simply to keep the branches thin. The tree when on the free-stock requires a great amount of head room. The best and most fruitful trees have heads with a diameter of over 30 feet, and will spreading. In some orchards the Blenheim

in some cases stock influences have contributed to a slight change of form or colouring. We understand there is a form of this Apple grown in Gloucestershire which is called the "Green Blenheim," and about it we should be glad if any of our correspondents would send us some information. At the great Apple Conference at Chiswick in 1883, the best fruits of Blenheim were sent by Messrs. Jefferies and Son, of Oxford, and the true and best type is supposed to be mostly found in that neighbourhood, having been raised in a garden belonging to a baker at Old Woodstock, near Oxford. It is found under many names in various parts of the country, some of its synonyms being Beauty of Hauts, Droggo's Fame, Gloster Pippin, Northampton, Prince of Wales, and Ward's Pippin.

The Apples figured were gathered in a small garden at Epsom from a tree supposed to be on its own roots, and somewhat old. It has not been very prolific for some years, but last year the wood was very heavily thinned, in conse-

Planting fruit orchard (J. T. N.).—As you wish entle to run occasionally in your orchard on Grass, it is evident that you must have your trees as standards on stems and heads 6 feet from the ground. For that reason only free or Crab-stocks can be used, but these will not force trees to fruit so soon as will bush trees on the Paradise-stock. That, however, cannot be helped. Of course, each tree-stem must be firmly staked and protected by wire or bushes from harm by cattle. You had better get, of Apples, Lord Suffield, Lord Grosvenor, Warner's King, Waltham Abbey Seedling, Newton Wonder, and Wellington. These are cookers, covering, as placed, a long season. Of eating Apples plant Mr. Gladstone, Worcester Purnain, King of the Pippins, Fearn's Pippin, and Sturmer Pippin, early and late varieties. The best Pears to plant would be Williams' Bon Chrétien, Louise Bonne, and Durodean, with the fine baking Pear Catillac. Plant of Plums Rivers' Early Prolific, Czar, and Wredale, and Crittenden and Bradley's

King Damsons. Apples should be 20 feet apart, Pears 18 feet, and Plums 15 feet at least, but all would be better if rather wider. In the garden, get for your 21 feet high wall Peaches Amsden June, Early Gros Mignonne, Royal George, and Ilymond, and Nectarines Lord Napier and Elruge on tall stems as riders, so as to have dwarf-trained Apricot and Peaches beneath the others. Plant the tall riders 16 feet apart, and one flat-trained tree between each. Brown Turkey is the best outdoor Fig, wanting a warm corner. Reine Olga and Sweetwater are the best Grapes for your verandah. Get all ground for fruit-trees deeply dug, but add very little manure. Plant so soon as you can get the trees now. The Corsican Pine will be the best evergreen trees to hide a building quickly.

CHRYSANTHEMUMS.

EARLY-FLOWERING CHRYSANTHEMUMS AT TAMWORTH.

THE trial of these, made by Mr. William Sydenham, at Tamworth, has brought to light many excellent varieties of which comparatively little was known. The high quality of many of the Japanese and Pompon sorts proved the value in the open garden of the early-flowering Chrysanthemums in the dull autumn months. Some three thousand plants, in about two hundred and fifty varieties, were grown, plants being secured from almost every available source, thus making the display a most comprehensive one. The plants were put out in long rows, with a space between each plant of about 3 feet. Between each two rows of plants a good pathway was provided, and this enabled the visitors to inspect the collection with the greatest ease. Being arranged in alphabetical order, it was an easy matter to fix the name of any sort. It must be admitted that in planting in alphabetical order the best effects were not obtained. For instance, a plant some 4 feet to 5 feet in height was followed by another some 18 inches to 2 feet in height, but then the general convenience of the visitors and others was the first consideration. A fact which was apparent to all was the natural lateness of many so-called early sorts. Quite a large number in the collection will not come into flower until the end of October, and others are likely to be still later. In making known these facts, Mr. William Sydenham will be conferring an immenso benefit on all who are now disposed to take up the cultivation of these plants. It is his intention to delete from his list sorts which fail to blossom within the prescribed period, beginning in August and concluding about the second or third week in October. Synonymous sorts are abundant in most lists of the early-flowering varieties, and to get these properly bracketed and the stocks brought under one name is an effort for which Mr. Sydenham deserves the best thanks. Some of the varieties of recent origin, which were sent out with a flourish of trumpets, have little in them to commend them. Many sorts which were certificated in recent years are not yet in flower, and there is little likelihood of their being in bloom for some time to come. This proves that new sorts should not be recognised unless they are represented as flowering from a terminal bud selection—i.e., the termination of the plant's growth. For the benefit of readers of GARDENING ILLUSTRATED, a brief description of some of the best Japanese sorts is appended:—

FRANÇOIS VILHEMNET.—A bushy plant, free flowering. Colour, lilac-rose. Height, about 2½ feet. In flower late September.

GOACHER'S CRIMSON.—A plant developing large blooms on stout, erect footstalks of good length, without disbudbing. Colour, rich crimson, golden reverse. Height, 3 feet. In flower during September.

CRIMSON MARIE MASSE.—One of the best of the earliest, free flowering. Colour, chestnut-crimson, passing to bronze with age. Habit, bushy and branching. Height, 3 feet. In flower from August till October.

PARISIANA.—A sparsely-flowered plant, developing larger blooms than most of the early sorts. It is a promising white sort, with long flower-stalks. Height, 3 feet. Period of flowering, September.

CHATEAU ST. VICTOR.—A useful plant, developing freely magenta flowers of pleasing form. Height, 3 feet. In flower September.

BRONZE PRINCE.—An English raised seedling of proved merit. The plant is fairly free flowering. Colour, old gold, shaded cerise. Period of flowering, mid-September to mid-October. Height, 3 feet.

Mons. GUSTAVE GRUNERWALD.—A useful plant for early displays. flowers large and of good form. Colour, silvery-pink, shaded rose. Fairly good habit, free flowering. Height, 18 inches. In flower August and September.

RABRIE BURNS.—One of the prettiest sports from Mme. Marie Masse; a profuse bloomer, each flower on a useful footstalk. Colour, salmon-pink. Habit, bushy and branching. Height, 3 feet. Blossoms from August till October.

BENJAMIN GUINDREAU.—A plant of which little has been heard. Pretty blossoms of a purple-amaranth colour. Habit, bushy and sturdy. In flower during September.

ARTHUR KEDZIE.—An English raised, promising seedling with pretty little blossoms of much value for decoration. Colour, bluish-pink, shaded salmon in the centre. Dwarf and sturdy habit. Height, 2 feet. In flower during September.

ALBERT ROSE.—This produces a dense mass of blossoms of a distinct shade of rose colour. Habit, bushy. Height, 3 feet. In full blossom during September.

M. LEVEQUE PERE.—A very dwarf plant, developing large blooms. Colour, crimson and bronze. Sturdy grower. Height, 18 inches. In flower mid-September to mid-October. This variety is considered by many to be the same as Gladys Irene Harkness.

ERNEST MATHURU.—This is a very bushy and free-flowering plant. Colour, light salmon, shaded yellow. Height, 3½ feet. In flower from early September till October is well advanced.

DURHAM KING.—A very useful plant, producing bunches of reflexed blossoms. Colour, deep pink, striped light pink. Height, 2 feet. In flower during September.

DORIS PETO.—An English raised seedling of considerable promise. The blossoms are of good form and pure white, and each bloom has a good length of flower-stem. This variety is generally considered to be an improvement on Mychett White. Height, 2½ feet. In flower during September.

MME. CASIMIR PERRIER.—In this plant we have a variety of high merit. Little has been heard of it, yet the plant may be regarded as one of the best. Bushy and free flowering. Colour, creamy white, freely tinted pink. It is also a flower of beautiful form. Height, 3 feet. Period of flowering, September and early October.

LOUIS LEMAIRE.—This is a sport from Mons. G. Grunerwald, and partakes of all the excellent qualities of the parent; flowers large. Colour, yellow, shaded orange. In flower August and September. Height, 2 feet.

LEONARD PETO.—A seedling from Lenon Queen, and which should be in all gardens. The plant is literally smothered with dainty bright yellow blossoms. Habit, bushy and branching. Height, 3 feet. In flower during the whole of September.

LEMON QUEEN.—A valuable plant for late September and October displays. Flowers large and of good form, withstanding wet weather well. Colour, orange-yellow. Height, 3 feet. A profuse bloomer.

IRENE HUNT.—In this variety we have a distinct acquisition. Its chestnut and gold colour stands out distinct from all others. Very free. Height, 3½ feet. In flower during September and early October.

HORACE MARTIN.—A rich yellow sport from Crimson Marie Masse. This variety is the finest acquisition to the early-flowering section for many years, and no garden should be without it. Habit, branching and free flowering. Height, 3 feet. In blossom from August till October. W. V. T.

Request to readers of "Gardening."—Readers, both amateur and in the trade, will kindly remember that we are always very glad to see interesting specimens of plants or flowers to illustrate, if they will kindly send them to our office in as good a state as possible.

GARDEN PESTS AND FRIENDS.

American-blight on Apple-trees.—I should feel obliged if you will kindly advise me what to do to get rid of the insect, a sample of which I send you. The tree is covered with them, and has borne no fruit this year. It was lined at the beginning of the year, but that had no effect, and I am afraid of its spreading over the garden. J. H. DICKSON.

[The insect which is attacking your Apple-trees is American-blight. Get a little paraffin, and with a brush daub it well in where the insects are. A little later wash them out with strong soapy water, then mix a little soap, clay, and paraffin to make a paste, and daub it into any cracks or wounds in the bark where the insects are. If any appear later—and the summer is the chief season for them—follow up with the treatment first advised.]

The Gooseberry Caterpillar.—These last two seasons I have been plagued with the caterpillar on my Gooseberry-bushes and Currants, and have had to see fellows go to destroy them, and also hand-pick them. Can I do anything now to prevent this occurring next season? Would dressing the ground with gas-lime below the bushes help? I would be glad of your advice.—E. H. GOSWELL STRILAND.

—The foliage of my Gooseberry-bushes is just now being devoured by a small green caterpillar with black head and small black spots. On many of the bushes not a single leaf is left. I should be glad to know how best to get rid of this pest.—H. L.

[At this time of the year all caterpillars that infest your bushes are hibernating in the soil as chrysalides. If you could fork up the soil round the bushes so soon as the leaves fall, and could turn fowls in among them, they would destroy great numbers. You could fork again a few weeks later. Failing this, let the soil over all the same, then strew about beneath the bushes gas-lime well broken up. Put on at the rate of half a bucket per rod, but let it be thickest close under the bushes. In the spring, after the flowers have set take advantage of a damp evening and smother the bushes with soot.]

Woodlice in Peach-house.—Many of the Peach-trees in a cold-house are each season destroyed by woodlice. The walls (which are of old brick) were plastered last winter, in the hope of getting rid of these insects, but they seem to come up out of the ground. I managed to keep them in check to some extent this year by the use of woodlice powder. I should like, however, to know if it is possible to do anything towards really exterminating them before next fruiting season?—H. L.

[One of the best ways of destroying woodlice is to pour boiling water over them, as it kills them in a wholesale manner if you can find out where they congregate. They are fond of hiding under bricks, slates, tiles, pieces of board, etc. Lay some of these about and lift them every morning. They may be poisoned by boiling small pieces of Potato in water in which arsenic has been boiled. One part of Steiner's vormin paste mixed with three parts of Barley-meal, and put in small quantities on to pieces of slate, card, etc., has been very strongly recommended, also phosphorus paste spread on pieces of bread and butter. They may also be trapped by folding long strips of brown paper in half lengthwise, and smearing one side with treacle and beer, and laying them about in the haunts of the woodlice. They will creep into this shelter, and can easily be shaken into boiling water.]

Wireworm in garden.—My kitchen garden is so badly infested with wireworm that everything is eaten up. I have tried soil, salt, lime, but all to no purpose. I have not tried gas-lime, as I have been told that for twelve or eighteen months everything grown in it will taste of tar. Is this a fact? Can I do anything else to kill the wireworm? I have been advised to lay the garden down in Grass for two or three years, at the end of which time the wireworm will have disappeared. Is this so? If so, I should be glad if you would give me some idea as to whether it would be advisable to turn, say, one-third of it into a sort of rabbit-paddock or court (size 20 yards by 15 yards) I have no use for the Grass otherwise.—WARREN.

[You need not be in the least afraid to employ gas-lime as a dressing in your garden. There is no tar in it. Its chief constituent other than lime used to purify the gas is sulphuric acid; but any harmful effects that may have on crops is quite minimised if properly treated. Spread it so soon as ground is vacant at the rate of a bushel per rod, well breaking it, letting it be exposed on the surface for four weeks, and, as it breaks or pulverises, more evenly spreading it with a big rake, then digging it in to well mix it with the soil. It is the most potent destroyer of wireworm we have. You may give a dressing of manure, if you wish to do so, in February or March, well digging it in, and crap at once with perfect

safety. Laying down in Grass is the primary cause of wireworms, as the fly so readily deposits its eggs in the Grass, and birds cannot get at the wireworms.]

INDOOR PLANTS.

THE SCARBOROUGH LILY (VALLOTA PURPUREA).

This is one of the few Cape bulbs that have retained a hold on public estimation, and one often sees better grown plants of it in a cottager's window than are generally found in large gardens. One of the main secrets in its culture is to allow the bulbs to become thoroughly established. It dislikes frequent shifts, and never flowers so freely and strongly as when in a root-bound condition. It must have plenty of food during the growing season. From the time the plants start into growth until the flowers appear frequent supplies of

PROPAGATION.—To increase this it is only necessary to take off the small bulbs that form round the parent and put them into some sandy soil. If a dozen little bulbs are dibbled into a small pot and shifted on as they fill the pot with roots, never attempting to disturb them in any way, they will make rapid progress, and a large specimen will soon be had. It can also be easily increased from seed, which should be sown as soon as it is ripe.

POTTING should be done when there are signs of growth commencing, after which a little warmth for a week or two would be beneficial. Care should be taken that the plants are never overpotted, as greater success in flowering always follows if the bulbs are crowding one another out of the pots.

NOTES AND REPLIES.

Primulas.—Primulas of the *obconica*, *stellata*, and *sinensis* types should now be allowed to form their flower spikes, and may get a little liquid-manure occasionally.

of starting into growth, and directly this is soon they must be shaken clear of the old soil and repotted. As these Arums are liberal feeders, a mixture of 2 parts loam to 1 part each of leaf-mould and well-decayed manure, with a little sand, will suit them well. During the growing period they need a temperature above that of an ordinary greenhouse—indeed, filling an intermediate structure, they may be grown in the coolest part of the stove and hardened off to a greenhouse as spring advances. Take particular care that aphides do not attack the foliage.]

Amaryllis Johnsoni.—Enclosed is a flower from a spike of a bulb. Will you kindly tell me its name, how to grow the bulbs successfully, and when I should report them, and if I manage to save some seed when it should be sown, and when to expect seedlings to flower? I have three 5-inch pots full of the bulbs, of various sizes, as they increase very rapidly. In each pot are the same sizes of bulbs, and though all have been similarly treated—grown in a very sunny window—for some reason only one bulb has bloomed, with three spikes on as many bulbs. The first spike to flower had twenty-one blossoms, the first to open being 7 inches long, 8 inches wide (much larger than the one sent). I found, if repotted, all the roots died, so I have left them untouched three years. They have had water all the year, being evergreen, with much water and liquid-manure during spring and summer. But as I have been growing these bigger bulbs for six years, I consider they should have flowered before now, and should therefore be grateful for your advice.—FRANK H. W.

[The flower sent is that of *Amaryllis Johnsoni*, one of the oldest hybrids in cultivation, and, of course, vastly inferior to the newer forms. It is very free-flowering, but needs more heat than a sunny window to induce it to bloom regularly. The cultivation of the different hybrid *Amaryllises* has been so often dwelt upon in *GARDENING ILLUSTRATED* that little need be said on that point, but, briefly speaking, they are kept dry during the winter in a temperature of 50 degs. or thereabouts, then, with increased heat in the spring, they throw up their leaves and flowers. After blooming they are fully exposed to the sun in the warmest part of the greenhouse, and kept watered, till towards the end of the summer or in early autumn the leaves die off, after which they are kept dry throughout the winter. This is by far the most successful way of flowering them, the thorough ripening of the bulbs thus ensured being very necessary. If treated as evergreens, very few flowers are ever borne. Repotting is done early in the season before the bulbs start into growth, but this need not be done annually; indeed, they will often stand for several years and flower well without being potted. Your plants are flowering unusually late, so that there will be little time to ripen off the bulbs this autumn. We should, however, advise them to be kept dry throughout the winter, when, with the return of spring, if given more moisture at the roots, they will in all probability start into growth and flower earlier next year. The seed should be sown in the spring in, if possible, a temperature of about 60 degs., and if grown on freely the strongest bulbs will take three years to flower. The young plants must not be rested during the first winter, and only to a partial extent the second. The word is pronounced *Amaryllis*.]

Bulbs.—This is the month for bulbs, and if it is wished to succeed well, every precaution should be taken as advised in a previous number of *GARDENING ILLUSTRATED*. Often when one is uncovering his pots after six weeks' plunging, the delicate green shoot of the

The Scarborough Lily (*Vallota purpurea*).

guano, root, or manure-water are very beneficial. The *Vallota* should never be dried off. As the winter advances, the supplies of water have, as in the case of most other plants, to be lessened, but moisture at the roots should never be entirely withheld. A certain amount of foliage should be left to draw up the sap and start the bulb into fresh growth early in the spring. Another important point during the winter is to see that the plants have plenty of light, as it has been found that plants which enjoyed a maximum of light during the dull months of the year have invariably flowered the best. Where any quantity of bulbs is grown, a succession of bloom may be kept up by placing a few new and again in heat in the early spring.

Soil.—With respect to soil the *Vallota* is not at all fastidious, a mixture of loam and peat with some sand suiting it well. A porous compost is indispensable, as the roots being thick and fleshy cannot well exist in soil that is of a close nature.

The first-named does in a cool-house, but the others require some heat, say 50 degs. to 55 degs., to flower them properly.—D. G. McIVER, *Bridge-of-Weir, S. B.*

Growing yellow Arums.—I have just had sent me four bulbs of a yellow Arum from South Africa, and should be glad to know how they should be grown. I have been very successful with white Arums, and have a greenhouse with no heat, except a small stove in very cold weather. The bulbs are beginning to shoot.—J. V.

[Failures in the culture of the yellow Arums are frequent, the principal cause being that they are often spoken of as, except in colour, a counterpart of the common Lily of the Nile, whereas in reality they require totally different treatment. In the first place, they are natives of a much warmer district than the white-flowered kind, which occurs in Cape Colony, whereas the yellow-flowered forms come from much further north. Then they form a roundish tuber, which pushes up its foliage early in the year, then flowers, and towards the end of the summer goes to rest, during which it should be kept quite dry. About the end of the year they will generally show signs

be done annually; indeed, they will often stand for several years and flower well without being potted. Your plants are flowering unusually late, so that there will be little time to ripen off the bulbs this autumn. We should, however, advise them to be kept dry throughout the winter, when, with the return of spring, if given more moisture at the roots, they will in all probability start into growth and flower earlier next year. The seed should be sown in the spring in, if possible, a temperature of about 60 degs., and if grown on freely the strongest bulbs will take three years to flower. The young plants must not be rested during the first winter, and only to a partial extent the second. The word is pronounced *Amaryllis*.]

Bulbs.—This is the month for bulbs, and if it is wished to succeed well, every precaution should be taken as advised in a previous number of *GARDENING ILLUSTRATED*. Often when one is uncovering his pots after six weeks' plunging, the delicate green shoot of the

Hyacinth, or whatever it may be, is bruised and broken. To prevent this place a thumb-pot over the bulb after potting, or if there is a number of bulbs invert a pot of the same size as the bulbs are in over them, which will ensure their safety. This system is much in vogue with exhibitors, but I fail to see why it should not be adopted by gardeners and amateurs alike. Roman Hyacinths which were potted or boxed at the beginning of last month may now be removed to heat, shading them for a few days till they are somewhat murred to the light.—D. G. M.F.

TREES AND SHRUBS.

RHODODENDRON AUCKLANDI (GRIF-FITHIANUM) AND ITS HYBRIDS.

Rhododendron Aucklandi is one of the finest members of the family, but being tender and requiring a good-sized structure for its development, it is uncommon. Though unsuited for outdoor culture, some of the limited number of hybrids raised from it are quite hardy and valuable from their distinct character. Such an one is Pink Pearl, of which R.

Veitch and Son between *R. Aucklandi* and a garden form known as *allanum grandiflorum*. It is a very pretty variety, whose saucer-shaped blooms are pure white, except a few roddish spots on the inside. Many other cultivators have obtained hybrids between *R. Aucklandi* and other forms, but they have not become generally cultivated; indeed, of those above-mentioned the only ones that are readily obtainable are Pink Pearl and Manglesi.

Their cultural requirements in no way differ from those of the other garden forms of hybrid *Rhododendrons*—that is to say, a fairly moist soil, containing at least a good proportion of vegetable matter, while if they can be planted so as to be partially sheltered from spring frosts, so much the better, as *Kewense* at least is rather apt to start early. T.

CLIMBERS FOR COTTAGE.

I HAVE a long, low, double cottage (sketch enclosed), naked slope, in Swiss cottage style, in a northern county in Ireland, which I should like to stow with choice creepers, and, not knowing enough about plants to arrange a scheme of foliage and bloom which would give a picturesque effect summer and winter, I should feel obliged by the Editor's kind assistance. My idea would be to work out a scheme which would make the long frontage one harmonious stretch of varied tints of foliage

and lavender shades; Anderson's Henry, white, very free; Lady Caroline Neville, white, suffused red; Mme. Van Houtte, large white, free; Jackmani, snow white, are the best whites. If you plant Clematises alone, the better way would be to plant two of each to obtain quicker results. Of Roses, Aimée Vibert, white; Alister Stella Gray, orange-yellow and straw yellow; Mme. Carnot, golden-yellow; Climbing Perle des Jardins, yellow; and W. A. Richardson, orange and yellow. You may also increase the number of *Pyrus japonica* (the red kind), and, if the conditions favour, you may employ the pretty blue-flowered *Ceanothuses*, that should do quite well in your case. If you prefer it, the Roses and Clematises may be planted in conjunction with each other. It may also be possible in the central part to plant the free-growing Crimson Rambler Rose, which is a great success where it obtains room. The strong-growing Virginian Creeper—i.e., *Ampelopsis hederacea*—you do not appear to have room for, unless you could allow it on the roof. If this were permissible we would like to name two fine plants giving snow-white masses of bloom—*Clematis montana* in spring, and *Clematis Viticella alba* in late summer. Of the latter we have in mind an instance where it covers the small-leaved Virginian Creeper with its pure blossoms, and makes a picture of rare beauty indeed.]

Flowering climbers.—Your correspondent, "S. W. F.," in his very interesting article on "Flowering climbers," in your issue of the 20th of September does not mention a creeper which I have lately seen growing and flowering in the greatest profusion. I allude to *Solanum jasminoides*, a plant which will not, of course, grow everywhere. I have recently been staying at Minehead, and between that town and Porlock Weir several cottages were partially covered with this climber in full blossom, the large bunches of white flowers having the most charming appearance, reminding one of white *Plumbago* more than of anything else. I had never seen it growing out-of-doors before, and was much struck by its effectiveness when grown against the wall of an old cottage, climbing about at its own sweet will. To judge by the way many plants grow, the climate of Minehead and the neighbourhood must be a very mild one; the plants in all the gardens seemed to grow in the greatest luxuriance. At Dunster Castle there are two Palms near the Castle which are said to stand out all the year, and there is also a Banksian Rose growing to a height, and hanging in festoons in a way I have never seen before. Close by it is a very fine *Wistaria*, which also grows to a great height; against one of the walls is trained a Lemon tree, some 9 feet or so high, bearing a very fair crop of fruit, some of which are quite ripe. In the winter, however, it is protected by some glass lights, which are placed in front of it. There are some common Laurels in the grounds which have grown into trees, and quite puzzled some of the visitors who were being shown round as to what they might be. They were fruiting well, some of the berries resembling small Cherries, which also caused surprise.—G. S. S.

Hardy herbaceous plants.—In planting new borders with hardy herbaceous subjects, or in replanting old ones, from the second week in October to the middle of December, provided frost does not hinder, is the best time of the year to proceed with the work. In old borders, for instance, one can generally locate the whereabouts of certain specimens, because of the foliage, etc., which still remains; but when one puts off the matter until spring there is a likelihood of thrusting the spade through clumps, unless each root has its own labels, a precaution which is not always followed; moreover, the plants which are divided, say, in November, and placed in new quarters, get established by spring fairly well, and, this being so, their chances of blooming another season are much greater than newly-planted stuff. That it is needful for many plants of a herbaceous nature to have an overhauled and dividing at stated periods is admitted, and one has only to leave for a few

Rhododendron Pink Pearl.

Aucklandi is one of the parents. The flowers of this, which are borne in somewhat loose trusses, are individually about 4 inches across, and of a delightful shade of clear rose-pink, with but a few small brownish spots upon the upper segment. It has, within the last two or three years, made great headway in popular favour, and the demand for it is so extensive that it still realises a comparatively high price. It was raised and distributed by Messrs. John Waterer and Sons, of Bagshot, and was first shown by them in the spring of 1887, when it was given an award of merit by the Royal Horticultural Society. Three years later this was increased to a first-class certificate.

A beautiful series of hybrids between *R. Aucklandi* and *R. Hookeri* was raised at Kew, and the different members have proved to be perfectly hardy there. To this group the collective name of *Kewense* has been applied. In these different forms the flowers vary from pure white to a deep clear rose, which last is almost crimson when in the bud state. In all of these the flowers are shallow and the trusses loose, as in the typical *R. Aucklandi*. There is undoubtedly a great future before the members of this group, but up to the present they are scarcely to be obtained from nurseries. The variety *R. Manglesi* was raised by Messrs.

and contrasting blooms, and which would not be very bare in the winter. I have already some very scarlet *Pyrus japonica* and a young variegated Ivy. Would the Editor kindly suggest a combination of creepers that would suit this peculiarly long and low frontage, and bring out strongly the high parts in the centre? One half of the frontage might be a duplicate of the other, starting from the centre. I have a fancy for the light-colored Clematises, Virginian Creepers, Roses, and Vines (for foliage only). The aspect is very sunny, and sheltered from cold winds. It is south-west, nearly south.—T. B. D., Ireland.

You could with advantage employ any of the following plants, all of which are good for walls, and not too luxuriant. For the highest portion you could use the Coloured Vine (*Vitis Cœlestis*) or the purplish-leaved form of the small Virginian Creeper, both notable for colour effect in autumn. Other good plants may include *Lupinus arboreus*, yellow, very free, requires slight fixing. Any of the *Weigelas* are good, flowers of varying rose and red tints. *Cratægus Pyracantha* and its variety *C. Lelandi* are docket with scarlet berries a long time in autumn, and very fine in effect. The finest silver-leaved Ivy is *Hedera madeirensis* fol. var., or *Euonymus radicans variegata* is more than its equal as a silver-leaved wall plant, self-adherent too. Light-colored Clematises should include *Lady Lonsdaleborough*, *Wm. Kennett*, *Lord Lonsdaleborough*, *Lady Boville*, all of the silver-crested

years clumps of Rudbeckias, Starworts, Delphiniums, Phloxes, etc., to find out how ungainly they become, and, what is as bad, how they degenerate in the quality of their blossoms.—LEAURST.

VEGETABLES.

THE POTATO CROP.

Now the crop is being lifted we shall be able to form some opinion as to what extent the disease has extended among the tubers, and it would be interesting reading did the many writers in *GARDENING ILLUSTRATED* tell us how their crops have turned out and what varieties have taken the disease the worst. It would be more to the point did they tell us what kind of soil they have to contend with. I do not grow many varieties for late crops, and stick to those I find do best after some years' trial, of course, keeping flavour uppermost, however good a cropper a variety may be. *Magnum Bonum* used to be the standard sort, but of late it has not done so well as formerly, though I am not sure whether I shall not have to hark back and give it another chance. This year many of us will be tempted to give *Northern Star* a trial. It appears to be disease-resisting; if so, and the flavour not so good as could be wished, perhaps some of our raisers will improve matters in this direction.

From my experience the Potato crop is not

been very much better in quality and less free of disease had artificial manures been used. This is why I think contributions from your many readers would prove instructive if they would kindly name the sort of soil, manures used, and varieties planted. I think a great mistake is made in not changing the seed oftener than is done, procuring it from quite a different soil from that in which one has to grow tubers. EAST DEVON.

WINTER PROSPECTS FOR VEGETABLES.

I HAVE been taking stock of my garden crops, and, so far, think that generally the prospects for the winter are very fair. All my Potatoes have been lifted, and these, I regret to say, are my poorest crop. The Potato crop has been very disappointing; with the early ones many seed-tubers failed to decay, and, as is always the case, the crop of new tubers was poor on all those plants. Quite one-third of the plants came very weak—a general feature with Potatoes this year—and last of all there is a good deal of disease in the late ones, so that the general crop is from one-third to one-half less than has been lifted in some previous years. The Parsnip breadth is a good one, the roots being of good size and sound. Maincrop Carrots, too, are good, although not over-large, which is no defect, and I have from a July sowing a bed of young Carrots, from which very many pullings of soft, sweet young roots

There is in the garden a nice breadth of Snowball Turnips now being pulled from a July sowing, and a second sowing made in August has been thinned and hoed, and will give plenty of nice bulbs in a week or two. Besides these I have a few rows of Golden Globo Swede Turnip, sown late to secure medium-sized bulbs for cooking in the winter. These, if not large, make very nice food indeed. Late Peas are over, but there is yet plenty of Runner and Dwarf Kidney Beans from late sowings. At this time of the year early sowings of Runners are often over, but it is then that a June sowing proves to be so useful. This sowing is always made in a sheltered position to enable the Beans to escape early white frosts. I hope to have plenty both of Runners and of Dwarfs by covering up the latter at night till the end of October. Marrows have of late felt the cold nights very much, and are practically done, yet they have, during the all too short season, rendered good service. If a few plants could be protected early in September under a large frame, fruit might be had until the middle of October at least.

All outdoor Tomatoes have failed, owing to the coldness of the summer. Next year I shall put out plants only that have been got into 6-inch pots, are 18 inches in height, and, if possible, have set one truss of bloom. That can be done in a greenhouse. The Tomato plants in the greenhouse have given a good crop, but they will soon have to come out as the house is wanted for other things.

The great winter crop is, of course, the Cabbage tribe. Of late winter plants, there is plenty yet to be got out during October. There is a breadth of *Ellam's Early* well established to give small heads in February, and there is a small breadth of *St. John's Day* Cabbage ready for cutting now. Savoys will be plentiful later, but they are yet small. With a wealth of Autumn Giant Cauliflower turning in, Savoys are not wanted, and there will soon be plenty of Brussels Sprouts, for growth is remarkably good. I have nice Blood Red Cabbages. There is plenty also of late Kales, Sprouting and White Broccolis. Not least, there are several rows of good Celery. So far my garden gives every hope of supplying an abundance of vegetables all the winter.

GARDENER.

PREVENTION OF THE ONION FLY.

GENERALLY the plot intended for the Onions is that which was previously occupied by Cabbage or some of the Brassica family. Very likely it will have the refuse of the previous crop left on it for the purpose of being dug in. If there has hitherto been a difficulty in securing a clean crop of Onions, this is a very questionable proceeding, as amongst such refuse the pupæ are apt to harbour, and the better method is to clear it off. The soil should be dug deeply with forks and thrown up roughly, and immediately afterwards have a light dressing of gas-lime—not a heavy dressing by any means, as this might have as bad an effect upon the Onions as the grub, but just sufficient to colour the surface. The soil should then be forked over, and if possible again during the winter. This forking over will bring the pupæ to the surface to be acted upon by frost. If gas-lime is not procurable, use freshly-slaked lime. More surface will be exposed if the soil is ridged, the frost also working right through it. The fault with trenched soil for Onions is that it is apt to favour thick necks and late maturing, especially if the season should be wet. If trenching is intended, rather depend upon bastard trenching, which should be done in the autumn. The manuring should take place about a month before the time intended for sowing, at which time the spring precautions should commence. These will consist of dressing with wood-ashes, soot, and a little salt, each of which, besides being of great value in combating the fly, is also a capital fertiliser. Lime should not be used at this time; not that it would prove injurious, but it would counteract the influences of the soot and salt. Soot is very distasteful to the fly, and a freer use of it would prove beneficial in those gardens where these insects cause such destruction. With salt more care is needed, but a little used judiciously is of great benefit.

Potato White Elephant.

nearly so bad as some writers would have us believe, though my soil being fairly light, no doubt I have fared better than those who have a retentive soil to deal with. I am speaking now of the main crop grown out in the field, which only comprises three varieties—namely, *White Elephant*, *Up-to-Date*, and *Imperator*, the first turning out by far the best and with fewer small ones than for many years past. This is of good quality, and usually fetches a much better price than any other variety grown around here, and is more cultivated than the other two varieties put together. For the past two or three seasons, while being fairly free from disease, the tubers of *White Elephant*, or a great many of them, when cut have a dark ring round them, and last year scores of bags were quite unsaleable on this account. *Up-to-Date* proves a good late Potato and keeps well into June or even July. *Imperator* crops heavily and is good in quality late in spring. Earlier varieties grown in the garden, such as *Sharpe's Victor*, *Puritan*, *Improved Ashleaf*, *Reliance*, *Surprise*, and *Satisfaction*, were, with the exception of the first, badly diseased. *Improved Ashleaf* and *Satisfaction* are more heavily cropped. The ground in garden and field had a fair dressing of stable-manure and partly decomposed leaf-soil, not by any means heavy; but there is not the least doubt, could anyone have foreseen the cold, sunless season we have had, Potatoes in general would have

will be had during the winter. There are also a few rows of the far from commonly-grown root *Salsafy*, which, when well grown, is delicious if properly cooked. I wonder in how many gardens can be found a few rows of *Witloof Chicory*? Of this I have several, because the roots, after the leaves have died down, are lifted and placed, a few at a time as wanted, into a dark, warm place in soil, and well watered, produce a blanched and most delicious form of salading. As for *Seakale*, I have a breadth of some 500 plants. These, again, will, during the winter, the roots being treated as is the *Chicory*, give stem growth well blanched, tender, and of the nicest possible description. It is but needful, as the roots are lifted later, to cut off all the side roots, make them into root cuttings, lay them in thickly for the winter, then dibble them out into well-prepared soil in rows about 20 inches apart, to have plenty of fine *Seakale*-roots and crowns next year. Another good root crop is *Beet*. The globo-rooted ones have been pulled and eaten long since, and now the top-rooted ones are being used. Still, these will, if left, continue to grow well till the end of November, and then they will be lifted and stored in sand for use as needed. Good *Beet* ranks amongst the most nutritious as well as pleasant eating of all roots when properly cooked. I grow the *Cheltenham Green Top* and *Blood Red*, both having the grain and rich colour.

Before the soil is broken down after being laid up to the action of frost, the burned refuse should be first spread on and then a good dressing of soot, the whole being now knocked over with a coarse rake, this operation working the ingredients into the top 2 inches of surface. The whole surface having now been equally trodden over, a mere sprinkling, or about an ounce to the square yard, of salt should be applied. The drills having been drawn and the seeds sown, nothing more will be necessary until the young Onions have grown 2 inches or 3 inches. At about this period the fly emerges from its pupæ stage, and soon commences to look about for a suitable place to lay its eggs. This is just within the outer edge of the skin of the young Onions and close to the ground. When attacks are known to have previously taken place, it is unwise to wait until the effects of the injury are visible before applying a remedy. It is better by far to adopt the same tactics as with Celery—viz., dusting the foliage over with soot, or syringing with well-diluted petroleum. A decoction of Quassia, and a suitable insecticide mixed with it, would be useful. If the whole quarter is syringed over at weekly intervals, the flies would not care to settle.

There is no mistaking the presence of the grub when once the work of destruction has begun, for the young Onions take on a yellow cast and the tops fall over. When this occurs, although there is not much likelihood of making a clearance, it may be checked considerably by digging up all affected plants and burning them. If merely pulled, the grubs are apt to be left behind. As there are two or three generations until the season occurs for them to enter the pupæ stage, remedial or preventive measures should be persisted in up till mid-summer. As the Onions are harvested take care that all trimmings are cleared away and burnt.

Transplanted Onions are seldom, if ever, affected, and this has led to the plan, where the grub is such a pest, of sowing the seed in a prepared cold-frame, and as the plants become large enough they are transplanted. Onions treated in this way grow to a large size, and they also ripen up well.

SOME LETTUCE OF THE SUMMER.

THE demand for Lettuce is governed in some seasons very much by the state of the weather. Thus, while in hot weather they are much sought for, in cool summers they are not so much in request. Few can complain of the great heat of the past summer, though for a short period the temperature certainly did assume a tropical nature. Previous to and since that short term there have only been fitful summer periods, cloud and wet more than drought preponderating. One would naturally expect that the demand for Lettuces would continue at low ebb. This, according to my experience, has not been so, but, instead, fewer heads were wasted than usual, from the fact of the demand being equal to the supply, despite, too, that from twenty to thirty dozen were cut weekly throughout the summer months. Names of Lettuces are legion, all more or less distinct and good. I do not propose giving a list that would suit any or every summer or any kind of soil, because that would be almost impossible, for the variation of weather and its influence on land and crop render a good Lettuce in one season almost worthless one in another. Transplanted Lettuces usually are more prone to run to seed prematurely than are those sown on the land they are intended to occupy, and for this reason I invariably sow permanently during the later months of the summer. I am not quite sure, but to me it seems no crop so markedly shows the influence of a declining sun. In the summer, given favourable weather and treatment, Lettuces go forward and soon come to maturity. In the autumn it is different, for unless they have a good open site their growth becomes, at any rate in the Cos section, attenuated and thin. There is an absence of the full heart which one so much enjoys and expects in summer, outer leaves taking precedence over the tender, unfolded and easily-digested hearts, and a greater length of

time is required to get them ready for use. The different kinds of Superb White Cos have this summer been exceedingly good and of large size. A most distinct and wonderfully good Cos Lettuce is Little Gem. No variety that I have grown has pleased me so much as this. On the ground it may, in some stages of its growth, be taken for a Cabbage variety, but a closer examination of it will soon decide its class. Continuity, which in a dry season is so good, did not develop the same fullness of head this year. It is a good drought resister, and Marvel, which is slightly darker, is similar. Perfect Gem is fine for early summer, and so are Favourite and New York, two curled-leaved Lettuces. Intermediate, a dark-leaved kind, said to be the result of a cross between a Cos and Cabbage, is a good summer and autumn Lettuce. For early summer use Commodore Nutt and Paris Market are good, while the good old sort, All-the-Year-Round, must certainly not be despised. Though Hicks' Hardy White is a good winter and spring variety it is also a very good summer one. The multiplication of varieties is scarcely called for, when the perusal of catalogues from the best seed houses reveals the better and more profitable kinds. The season, however, has taught one useful lesson, which is not to depend on any one kind with the hope of finding it suitable for every season alike, wet or dry. W. S.

NOTES AND REPLIES.

Pea Gladstone.—I enclose four pods of Gladstone Pea, from a dish picked to-day, October 6th, in confirmation of your remarks upon this fine kind in a recent issue; nor is this the last gathering from the row.—A. HOBKINSON, *Frame*.

[Pods fresh and green, each containing on an average nine fully developed Peas of excellent flavour.]

Potatoes on meadow land.—I am hoping to plant Potatoes on new ground—meadow land—which is to be double dug. The soil is sandy. Would you advise me to have any manure dug in? I shall have the turf dug in.—TODD'AY.

[You should have no difficulty in securing a good crop of Potatoes from meadowland, the turf being well buried down. If in doing that you can well smother the turf when thus put down deep with plenty of fresh soot, it would later both act as manure, and help to destroy wireworms, should there be any, as is so commonly the case with old turf. If you can get that done early in the autumn it would be good policy to top-dress and fork in early in March a light top-dressing of stable-manure, rather short, and a few times turned before it is added. Then, being a sandy soil it should be easy to dibble in the tubers early in April. Take care and have good sound, well-stored seed-tubers, plant all about 5 inches deep, and give ample room. Crowding Potatoes in planting is bad policy.]

Cabbage for spring use.—Assuming that seeds were sown early last month, the little plants ought to be ready to transplant into nursery lines 4 to 6 inches apart by now. I always prefer to prick them out, instead of waiting until they are ready to be transferred from the seedling bed to their permanent quarters, especially the first sowing, as by so doing nice sturdy plants with good balls of soil attached to the roots can be got by the middle of October, when the removal will cause little or no check to the plant. Usually Cabbage follows Spring Onions and a wise course too, as the ground was got in good heart for that crop. After the quarter has been cleaned, fork up a piece large enough to take the plants, set them out with a dibber, afterwards applying water, if necessary, and scattering a little slaked lime if slugs abound. Most gardeners have their favourites, and after many trials I have failed to find a better early Cabbage than "Ellam's," very few bolting, as a rule. It is quite large enough for a gentleman's table, and it still has another advantage as closer planting than for larger varieties can be practised. I give 18 inches each way when put out in permanent quarters. As soon as the plants make a fresh start the soil should be stirred among them, and a watch kept for slugs; when towards the first fortnight in October they should be ready to transplant into drills, taken out with a mattock on the said Onion ground without any further digging. Loose soil should be well trodden before planting, Cabbage enjoying a firm root.

BOOKS.

"THE PRIMROSE AND DARWINISM."

Those who accept the Darwinians at their own valuation would be very much enlightened by reading this little book, which shows the shallow methods and hasty reasonings of much of the school of Darwin and Lubbock, not to speak of their wild followers, like the late Mr. Grant Allen. Darwinism was a sort of craze, and the followers of Darwin were pretty much like the florists of old, who would be inclined to knock anybody on the head who did not accept their little formulae. Darwin, as the result of observations made by him on the fertilisation of flowers, in the manner to be described later, drew several conclusions, out of which we select two, in order to show in part the author's method in dealing with them:—

"The first and most important . . . is that, generally, cross-fertilisation is beneficial and self-fertilisation often injurious." And, again: "Scarcely any result from my experiments has surprised me so much as this of the prepotency of pollen from a distinct individual over each plant's own pollen, as proved by the greater constitutional vigour of crossed seedlings." Furthermore: "The simple fact of the necessity in many cases of extraneous help for the transport of pollen renders it highly probable that some great benefit is gained; and this conclusion has now been firmly established by the proved superiority in growth, vigour, and fertility of crossed parentage over those of self-fertilised parentage."

We should here point out that by self-fertilisation is meant that the pollen of its own flower (or of a flower on this same root) fertilises its own stigma. By cross-fertilisation is meant that pollen from a flower growing on a different root (in case of heterostyled plants one of a different form) was applied to the stigma. Now Darwin, in making his experiments, made use of the following plan, as described by himself: "A single plant, if it produced a sufficiency of flowers, or two or three plants, were placed under a net stretched on a frame. On the plants thus protected" (from the visits of bees and other insects) "several flowers were marked, and were fertilised with their own pollen, and an equal number on the same plants were at the same time crossed with pollen from a distinct plant. The crossed plants had not their anthers removed."

To the efficacy of this method for giving any certain results the author makes the following objections:—

"The cross-fertilised plants had a great advantage. The self-fertilised plants had only their own pollen, and that developed under a net to fertilise them; but the cross-fertilised plants had not only their own pollen—their anthers were not removed—but pollen from another plant applied to them as well, and that, too, grown naturally outside the net; for Darwin wished, by leaving the flowers their own pollen, and, at the same time, crossing them with other pollen, 'to make the experiments as like as possible to what occurs under Nature, with plants fertilised by the aid of insects.' The cross-fertilised had, consequently, two sets of pollen to choose between, and whichever happened to be most in its prime, that would exercise a 'propotent' influence in the fertilisation. But the flowers fertilised with their own pollen had no other pollen but their own to depend upon, and that developed under a net, which must fertilise them or none at all."

Moreover, as the author points out, the flowers under the net were under the further disadvantage of being excluded from the full influence of the wind, whilst, on the other hand, a still further advantage was given to some of the crossed, in that, as Darwin says, they were "allowed to be freely crossed by the insects which incessantly visited them;" and this, as the author remarks, though the seedlings, which were raised from the seeds produced from the two sets, were afterwards to be compared in order to estimate the potency of self and cross-fertilisation.

"The influence of the solar rays, too, would

"The Primrose and Darwinism," by "A Field Naturalist," M.A., Camb. London: Grant Richards.

be greatly diminished in passing through a closely-meshed net, and consequently they would be much debarred from exercising their full maturing power on the anthers, and so on the pollen of the self-fertilised flowers. Radiation would likewise be almost entirely prevented by the net, and the dew would consequently fail to fall on the anthers. The importance of this influence cannot be over-estimated. In the mornings of early spring, after clear and still nights, we have frequently found the flowers of the Primrose bedrenched with dew. Occasionally the dew deposited on the anthers of the short-styled form has been so great as to lie upon the anthers and entirely to fill the orifice of the corolla. Thus the anthers of neither form could attain under such conditions their natural condition for fertilisation. The stigmas would likewise be similarly affected, as the cups of their flowers were likewise very frequently filled with dew."

As regards the other chapters of the book, we regret we have not space to attempt to do justice to the author's very clear and incisive arguments, notably Chapter XX., in which the Darwinian theory of a special relation between the stamens and petals of the same length in trimorphic flowers (different flowers of the same species, in which there are three different lengths of styles and stamens) is shown to be untenable. The book presents a clear case for the side opposed to many of Darwin's "facts." It is a plea for naturalism as against "net-ism."

GARDEN WORK.

Conservatory.—Tuberous Begonias and Gloxinias have now ceased for the most part to be attractive, and should be removed and encouraged to go gradually to rest for the winter. If kept dry, Gloxinias, though regarded as stove plants, do not require a stove temperature when at rest. They may be kept quite safely under the greenhouse stage, the pots being laid on their side till there is some sign of growth. The fibrous-rooted Begonias are now coming in, and will take the place of the tuberous-rooted kinds. Though the flowers of the winter-flowering sorts are smaller, they are produced very abundantly, especially such kinds as *Gloire de Lorraine*, which is one of the brightest plants for the winter in a moderately warm conservatory. As soon as the plants are fairly settled in their winter quarters it will be necessary to be on the look-out for insects. Green-fly is pretty sure to be present as soon as fires are lighted, if not before, and, if not destroyed, they will spoil the flowers and damage the health of the plants generally. Nicotine is the best remedy for insects, and the best mode of using it is to fill the house with the vapour, which is easily done in a simple way with a spirit lamp and a copper dish supplied by the manufacturers of the nicotine. It has been discovered that spraying with nicotine mixed with water is as effective as vaporising. Thus, if only two or three plants are attacked and if these are promptly dealt with, the insect attack may be nipped in the bud, so to speak, and a considerable saving effected. In the case of a conservatory attached to the dwelling-house, there is no danger of the fumes of the nicotine entering the dwelling-house and producing unpleasant consequences. When Cape Hosts and other hard-wooded plants are taken to the conservatory, they should be placed in a light position and be lifted up off the damp border or placed on a stage, if there is a stage or stand of any kind in the house, and the watering must have special attention. Hard-wooded plants do not require more water than other plants, but, if neglected, they will die. Other plants will recover from a deficient supply of water, but Cape Hosts seldom altogether get over a thorough drying, though they may linger some time. *Crowea saligna latifolia* is a pretty pink-flowered greenhouse hard-wooded plant in bloom just now, and not difficult to manage. *Salvia grandiflora* is very bright now, and a group or two will contrast favourably with the *Chrysanthemums*. Cuttings of this *Salvia*, rooted in February or later, will make good flowering plants the same season.

Stove.—Summer-flowering climbers, where trained under the roof, should have the growth reduced, as no shade is required for glass-

houses now. Even Ferns want all the light they can get now to harden growth. In pruning *Stephanotis floribunda* at this season thin out weak shoots, leaving strong ones a good length to flower, and training them in thinly to ripen. Get rid of mosly-bug by some means or other. Vaporising with nicotine will get rid of some of the old insects, and spraying with a solution of nicotine will be even more effective. There is a spraying apparatus in the market now which does not waste the mixture, and which will be found useful for dealing with single plants. Introduce a few pots of *Eucharis* from time to time from the cooler houses where they have been resting, and plunge in bottom-heat or stand the pots on a warm surface. Weak liquid-manure will give strength to the spikes and size to the blossoms. The usual winter-flowering plants will be coming on now in a night temperature of 65 degs., and, as many of these things may afterwards have to be taken to the conservatory, it will be better not to force too hard. Regulate the atmospheric moisture by the inside temperature and the heat of the pipes. Hard forcing will scarcely be needed yet to keep up the requisite temperature. The same rule applies to watering. Each plant must be treated separately and the knuckles brought to bear before applying the water-pot. Mistakes in watering now may have a far-reaching effect. *Achimenes*, *Gloxinias*, and *Caladiums* are now going to rest, and will require less water, but the drying-off should not be too sudden.

Pines.—Bottom-heat should range from 80 degs. to 85 degs.; atmospheric heat, fruiting houses, at night, 65 degs. to 70 degs.; successions, 60 degs. to 65 degs. The lowest point will usually be reached about sunrise, and the highest about the time fires are made up at night. The watering must be in careful hands; there is more danger in giving too much than too little, though either course should be avoided. Dew the plants over lightly with the syringe on fine days, and damp floors to give the necessary atmospheric humidity when required. Liquid-manure of the same temperature as the house should be given to plants swelling fruit until ripening commences. A look over twice a week will be sufficient now, and later, water may be required less frequently by plants plunged in moist bottom-heat-bed. Tree leaves form good plunging material mixed with tan, if tan is available.

Pruning early Peaches.—When Peaches are forced early, the trees must be pruned early, and it is not necessary to wait for the last leaf to fall, though early forced trees will probably be leafless now. Most gardeners nowadays go over the trees when the last fruits are gathered, and remove any of the wood which is not likely to be required, so that there will not be so much to do now. The main object is to keep the tree sufficiently filled with bearing wood in all its parts. The usual course is to remove all ties, and, when the pruning is finished, the branches are trained in such a manner as to completely fill the trellis. Before tying in the branches they are generally washed with warm soap and water, or a solution of Gishurst-compound is used. Apply it with a brush to the thick branches, and a piece of sponge to the smaller shoots, as it is important that the buds should not be injured. The sponge is drawn the same way as the buds project after the trees are pruned, washed, and trained, and the walls lime-washed. The borders should be top-dressed, removing some of the dry, exhausted soil from the surfaces before applying the fresh loam. The latter may be mixed with bone-meal. All fruits rovel in boxes in any form.

Cucumbers are now growing freely, and these plants set out early will be bearing. Only a light crop should be taken if the plants are expected to last through the winter. Night temperature, 65 degs. to 70 degs.; day, 75 degs. to 85 degs., according to outside conditions. Not much air will be required now, as it only wastes the fires.

Window gardening.—Fill window-boxes with small shrubs, or such hardy plants as Tulips, Crocuses, Narcissus, Wallflowers, Forget-me-nots, Violas. The new double-flowered *Arabis* makes an effective mass in a window-box, and a very cheap spring show may

be had by planting autumn-sown hardy annuals.

Outdoor garden.—There is plenty of good cuttings springing up from the centre of Pansies, which in many instances may be detached with roots, and if planted in a cold-frame in sandy loam, with a little leaf-mould, will make good plants in a short time. All kinds of improvements may be carried out now in the way of planting and turfing. The most important work in connection with planting operations is in the preparation of the ground. Nothing should be planted without breaking up the ground deeply. Even when single plants are dropped into an established shrubbery, a hole large enough to spread out all the roots and something more should be made. The time is at hand for clearing the beds of their summer occupants and filling in with spring flowers. Up to the present the beds of *Geraniums*, etc., have been very bright, and though there have been one or two light frosts no great harm has been done, and we are reluctant to pull up plants till the flowers fall. Beds can be cheaply filled with spring flowers by using autumn sown annuals and such biennials as *Forget-me-nots*, *Wallflowers*, *Cantorbury Bells*, and other *Campanulas*, especially the blue and white varieties of *C. carpatica*. *Primroses* and *Polyanthuses* sown early in heat and then pricked out in a shady border are now strong plants, and will flower in the spring. Though bulbs are cheaper than they were, if many beds have to be planted a good deal of money can be sunk in them. The cheapest things are Tulips and Crocuses. White Fox-gloves make charming masses among shrubs in the wilderness, and may be planted during the autumn.

Fruit garden.—Root-pruning, where necessary, should be done early in the autumn. Begin far enough away from the trunk of the tree, and sove as many of the smaller roots as possible. The work is usually spread over two years, but in careful hands the roots all round may be lifted and trimmed. Green Gage Plums when young seem on most soils to require root lifting and pruning a little to bring them into bearing. The Transparent Gage and Oullin's Golden Gage are more reliable than the old Gage. The latter only does well on certain soils. On the whole, this season has not been a good one for either the fruit grower or the consumer, as the fruit has been lacking in flavour from the absence of sunshine. There is no better bearing or handsomer Plum than the Victoria. It comes at a time when there is likely to be a glut in the market, but even then it pays better than most other kinds, and the tree is so vigorous and healthy. Monarch is a good Plum, and there is no better dessert Plum than *Coe's Golden Drop*. The two best dessert Apples in my opinion are *Cox's Orange Pippin* and *Lord Burgible*. The latter is in season from Christmas till March or later. Both require a deep, warm loam, and I have had them do well on the Paradise-stock.

Vegetable garden.—Look after Cauliflowers turning in; frost may come suddenly. Root crops may be lifted and stored. All roots, including Potatoes, retain their proper flavour best when covered with earth. If kept in a shed Beet and Carrots should be packed in sand. A stock of Horseradish should be lifted before bad weather comes and laid in on the north side of a wall where it can be easily covered. If any seeds of Peas remain in the seed-bags use them for producing green tops for flavouring. Sow them rather thickly in boxes any time during winter; but the later sowings should have a little heat under glass. The present dry, cooler weather will check the growth of late Broccoli, and if planted in firm ground, and dwarf and sturdy, they may pass through the winter safely without disturbance, but it is generally safer to hoist them over with heads to the north not later than the end of October. Those who want green Basil and Sweet Marjoram during winter will have potted up a few of the best plants and will keep them under glass, where a little warmth can be given. Beetroot is harder than is commonly supposed, but it is not wise to leave it exposed to severe frost. Lift at once, if not already out of the ground, and pack in sand in a stove or clamp the roots like Potatoes covered with earth. Those who desire early Asparagus

should prepare hot-beds now, and lift strong roots as soon as the bed is ready. Young roots four or five years old which have been specially grown for the purpose are best for early forcing. Prick off the early-sown Cauliflowers into frames for standing the winter. For the present only use the lights to keep out cold rains. E. HOBDAV.

THE COMING WEEK'S WORK.

Extracts from a Garden Diary.

October 13th.—Fruit-gathering is receiving attention every fine day. One need hardly say, this being a season of comparative scarcity, the fruits are handled carefully. The fruit-room was thoroughly cleaned before fruit-gathering commenced, and all wall surfaces lime-washed. Ventilation is given as required. Finished earthing up Celery and Caroons. Geranium and other cuttings have been moved on to shelves in houses, and for the present no fire will be used.

October 14th.—Cleared beds of the summer-flowering plants, and planted bulbs and other spring flowers. We are partial to Tulips, and usually plant decided colours, such as masses of scarlet, white, and yellow. Winter Aconites also are massed in open places under trees, and Snowdrops and Daffodils in open places anywhere. One never has too many Snowdrops, Scillas, or Chionodoxa Luciliae, and these can seldom be wrongly placed if in retired spots.

October 15th.—Made up a hot-bed for Asparagus with leaves and stable-manure. It takes rather a brisk heat to start the first batch of roots, but with five-year-old plants, which have not been cut from, the growth is early, and is always ready to start in warmth. We are always prepared to cover a bed of dwarf French Beans on a south border. A few lengths of builders' laths have been fixed temporarily to carry the covering, and, as they still bear freely, are worth a little trouble.

October 16th.—Another stir up with the fork has been given to the beds intended for the new Roses, and a little soot scattered over the surface and forked in. The ground at the season when the surface is dry cannot be too much stirred up and intermixed. More attention is given to planting in masses of one kind, especially where the beds are on the lawn; the beds are better filled and the effect is better. A hedge of rambling climbing Roses will also be planted. In fact, more will be done with Roses in many forms.

October 17th.—Lifted main bed of Carrots and stood in sand. Late-sown Early Horn will remain in the ground, and be covered with dry leaves and litter when frost sets in. Caniflowers are being watched with a view to afford protection when frost is expected. Of course, some plants have been lifted with balls and planted in deep pit to be safe in case of emergency. Potted and boxed more bulbs, especially Narcissus of sorts, Tulips, and Hyacinths. Green-fly is watched for in plant houses and the vapouriser used.

October 18th.—We are still doing some root-pruning among over-luxuriant fruit-trees, and stations for the planting of young trees have been prepared. Change of soil in the case of wall trees and espaliers is always carried out. Dwarf Apples are on the English Paradise-stock, and will soon begin bearing, but the best principle to work on is to give a plot of ground wholly to the trees, and mulch freely during summer with manure. This keeps the roots near the surface.

BIRDS.

Death of canary (P. H. Bearnley).—Inflammation of the bowels appears to have been the immediate cause of the death of this bird. This may have been brought about through its having taken a chill during its moult, or from the bird having partaken too freely of egg-food. Chills and draughts should be particularly guarded against during the moulting period, otherwise a check in the moult may result, causing illness or even death, and at the best leaving the sufferer ragged in its plumage for weeks. There is always the risk of a bird taking cold if placed at a window, as in such a position there is sure to be a certain amount of

draught. Yes, the moulting should proceed continuously, and a break of two or three weeks in the case of your bird would point to cold having been contracted at this critical period. Although food of a more nourishing character than the ordinary diet should be allowed a bird that is moulting, care is necessary lest an undue proportion of stimulating food be partaken of to the injury of the internal organs. It is not advisable to give egg-food oftener than twice a week. The seed at this period should consist of Canary, a little German Rape, and Linseed, with a pinch of Maw-seed occasionally. A tonic in the drinking water, such as a rusty nail or a little piece of sulphate of iron the size of a small Pea, will do good.—S. S. G.

POULTRY.

Young cockerels for table (J. Brown).—Cockerels at the age of five or six months should be in perfection for eating, and although they are liable to lose flesh as their bones develop, they certainly do not become tough till a much later period in their lives. Your feeding and treatment are excellent, and poultry that have been constantly well fed from their birth are not only always ready for table, but their flesh is superior in juiciness and flavour to that of those that have been specially fattened up. The killing of your cockerels two or three days before being required for table would still further reduce the possibility of their proving tough. There must be some fault in the cooking. If, in killing, fowls are bled to death, it may in some instances cause the flesh to become dry and insipid, but bleeding ensures great whiteness of flesh.—S. S. G.

BEES.

AUTUMN TREATMENT.

It is found that when Bees are fed late in the autumn they are often from the lowering of the temperature unable to elaborate wax for the capping of the cells or to evaporate the superfluous moisture from the food supplied. The consumption of unsealed, watery food during the winter is likely to produce dysentery in the hive, and, therefore, all good Bee-keepers ascertain the condition of their lives early in the autumn, and feed up where necessary without delay, that all may be in good wintering condition before cold weather sets in. Again, weak stocks are subject to this disease from their being obliged to consume an excessive quantity of food in order to maintain the necessary temperature within the hive. This may be obviated by making all colonies strong for wintering by joining two or more or adding them to stronger stocks. Colonies thus strengthened pass the winter safely, and are ready for work at the earliest possible moment in the following spring. Another cause of dysentery is dampness, arising either from lack of ample protection from the weather or from improper ventilation of the interior of the hive. In the case of the roofs of frame-hives, where not absolutely weather-proof, tarred brown paper makes an excellent overall. The old-fashioned straw-hackle makes a most excellent winter cover for skeps, as does roofing felt, which is very durable and impervious to water. When new it is stiff and hard, but it can be fitted to any hive by first warming it; but whatever kind of covering is used, care should be taken that it is so arranged that no drip shall fall upon the floor-board. Where the hive sides rest upon the floor-board the wet is often drawn under them, causing dampness within the hive. All causes of dampness should be removed as soon as discovered, and where a hive has become saturated with moisture the best thing to do is to change the frames of comb and Bees to a clean, dry, warm one.

The worst disease Bees suffer from is foul brood, which spreads very rapidly, so that in one season a whole neighbourhood may become infected with it. A colony attacked by this disease rapidly dwindles and dies out from inability to rear brood; other Bees pilfer the honey of the diseased hive, and so spread the infection. The cappings of cells containing

healthy brood are slightly raised, while the lids of those containing foul brood are somewhat concave and pierced. The latter appear singly on the brood combs, and are of a dark colour. Hives containing old combs appear to be more subject to this disease than those containing new, clean combs; it is well, therefore, to occasionally examine hives of old combs. Every endeavour should be made to stamp out on its first appearance a disease of so formidable a character, threatening as it does the destruction of the whole of the stocks in the apiary, to insure which the total destruction of all the combs in the hive is to be recommended. The hive should then be thoroughly scuffed, and washed well over with salicylic solution, made in the following proportions: Salicylic acid, 1 oz., soda borax, 1 oz., water, 4 pints.

As soon as the income of honey ceases, the queen discontinues laying, but brood-rearing may be encouraged after this period by stimulative feeding, whereby the population is increased till the latest period in the season consistent with safety, which is about the first week in October. After that time all colonies possessing less than 20 lb. of stores should be rapidly fed till that weight is made up. The syrup should be composed of sugar and water in the proportion of 10 lb. of sugar to 5 pints of water. In a general way each hive should contain 2 square feet of sealed honeycomb as well as that which is uncapped; the latter will serve as provision for the Bees till they settle down for the winter, although it is safer to remove all unsealed honey at this season lest it should cause dampness in the hive, and promote dysentery among the Bees. A piece of camphor, about the size of a Walnut, wrapped in some thin material, and placed on the floor-board of the hive, is most efficacious in warding off disease. The camphor evaporates slowly, and can be renewed as it disappears. To enable the Bees to easily pass from one comb to another, and to reach their stores, some apiarians form passage holes through each comb about 2 inches from the top, and $\frac{1}{2}$ inch in diameter. When, however, sugar-cake or caudry is given to winter upon, these passages are not necessary, as the space thus occupied gives the Bees passage way over the frames and under the quilts. Ordinary sugar-candy of trade is also good winter Bee food. S. S. G.

Colour of honey (C. B. Rigge).—There is great variety in the colour of honey, according to the particular flower from which it is gathered. Thus honey collected from white Clover is of a light straw colour, that from fruit blossoms a beautiful orange colour, from Heather of a dark reddish-brown hue, from Sainfoin, yellow, from Beans, brown, from Plum blossoms, a clear amber, while that from Lime blossoms is of a greenish shade, and of a strong flavour. The honey you describe was, no doubt, obtained from Lime blossoms. It would appear that in each of its excursions a Bee confines its foraging operations to one species of flower, and this would, of course, account for the distinct character of various honeys. The honey produced from ordinary feeding-syrup is of a light straw colour; if, however, dark sugar were used in artificial feeding, it might present a greenish tint in the comb. Honeydew, the product of various species of aphid, is a sweet, sticky substance found in dry seasons on the leaves of the Sycamore, Lime, Oak, etc. This, in times of scarcity of honey, is gathered by the Bees and stored in quantity. It is of a dark colour, has a strong odour, and is most disagreeable to the palate. Rhododendrons and Azaleas are said to yield honey of a crimson or reddish-brown colour, which is poisonous, and acts as a narcotic.—S. S. G.

LAW AND CUSTOM.

A market gardener's notice.—I took for market-garden purposes a garden and two greenhouses, but without the dwelling-house, and I am quitting, pursuant to proper notice, on October 11th. Can my landlady prohibit me from selling my goods by public auction on the premises? These are mainly pot plants. Can I claim compensation for growing crops?—T. C.

[If you have no written agreement of tenancy, nor any verbal stipulation to that effect, your landlady cannot prevent you from

selling your stock on the premises at any time before your tenancy expires. As you do not say what kind of growing crops are referred to, I may say that you cannot claim under the Market Gardeners' Compensation Act for any growing crops planted during the last year of tenancy and since notice to quit was given. You may claim under that Act for crops planted earlier, and which continue productive for two or more years. You may claim under the Allotments and Cottage Gardens Crops Act for growing crops planted in any year.—K. C. T.]

Right to minerals (A. B. F.).—An easement may be described as the right of the owner to exercise a certain privilege over the land of another owner. A "profit a prendre" is something in the nature of an easement. It is, however, something more, as it is a right to parts of the soil or the produce of the soil of another, such as a right to take turf, Grass, etc., from a common. Restrictive covenants, in this case, mean some covenant restricting the use to which the land may be put. For instance, a covenant prohibiting the erection of a particular kind of building, or of a building of a particular height, or a covenant not to erect a building in such a situation as to deprive some adjoining property of access of light, are restrictive covenants. I cannot tell without seeing the conveyance whether a right to take the minerals underlying the property is reserved either to the vendor or to a third party. Why do you not ask the solicitor who is acting for you in the matter? Unless the minerals are expressly or impliedly reserved, neither the vendor nor anyone else but yourself will have a right to them. Your solicitor should have ascertained by enquiry whether the vendor acquired the property subject to any such reservation, and your enquiry must be addressed to him.—K. C. T.]

Ownership of wall.—Fifty years ago my father bought a house which stood back some 30 feet from the road. There was then no wall dividing the plot of ground in front of the house from the plot in front of the adjoining house—or at most but a very short wall. My father built front walls, and ran out the dividing wall as an extension of the party wall of the houses. The owner of the adjoining house raised no objection, neither did he in any way interfere at any time. My father always regarded the wall up to his death, ten years ago. The house is now mine, and as the front walls of the garden fall I have had them rebuilt, and I repaired the dividing wall and put in a gate-post or pillar of the same width as the wall itself (15 inches). The present owner of the adjoining house caused his solicitor to write and charge me with interfering with his wall, but he admits certain rights of usage on my part. I have an idea he wants to extend in front of my property, and to use this dividing wall as his own. My deeds go back ninety years and contain no mention of these walls, but my neighbour's solicitor says his deeds go back 130 years, to a time when my house was not built. I believe, however, that both the houses belonged to my grandfather, and were then but one house. Can my neighbour claim any right to the wall either to build upon or for any purpose? When they found I was not willing to meet them in any way, they wrote that they would be willing the wall should be regarded as a party-wall or a half-wall rather than go to law. Your advice will oblige.—K. C. T.]

[On proof of the facts stated, that the wall was wholly or partially built by your father some fifty years ago, and that over since that time it has been solely maintained and repaired by your father and yourself, and that up to the present time your neighbour has never made any claim to any right or ownership to the wall, his claim must inevitably fail. No action can be brought to recover from any person possession of any land which he has held as of right for over twelve years, and for which he has paid no rent, given no acknowledgment, etc. You and your father have had undisputed possession of this wall for fifty years, and it is perfectly idle for your neighbour to make any claim to it. No matter what his original title may have been he has lost any interest in this wall that he or his predecessors in title may at one time have possessed.—K. C. T.]

Photographs of Gardens, Plants, of Trees.—We offer each week a copy of the latest edition of the "English Flower Garden" for the best photograph of a garden or any of its contents, indoors or outdoors, sent to us in any one week. Second prize, Half a Guinea.

The Prize Winners this week are: 1, Mrs. Bayldon, Dawlish, Devon, for Lillium longiflorum; 2, Mrs. Kennedy Erskine, B. ley, Montrose, for Rose Crimson Rambler.

CORRESPONDENCE.

Questions.—Queries and answers are inserted in GARDENING ILLUSTRATED free of charge if correspondents follow these rules:—All communications should be clearly and concisely written on one side of the paper only, and addressed to the Editor of GARDENING ILLUSTRATED, 11, Finsbury Street, London, E.C. Letters on business should be sent to the PUBLISHERS. The name and address of the sender are required in addition to any designation he may desire to be used in the paper. When more than one query is sent, each should be on a separate piece of paper, and not more than three queries should be sent at a time. Correspondents should bear in mind that, as GARDENING ILLUSTRATED is sent to press some time in advance of date, queries cannot always be replied to in the issue immediately following the receipt of their communication. We do not reply to queries by post.

Naming fruit.—Readers who desire our help in naming fruit should bear in mind that several specimens in different stages of ripeness, or of the same kind, are greatly assist in its determination. We have received from several correspondents single specimens of fruits for naming, these in many cases being unripe and otherwise poor. The difference between varieties of fruits are, in many cases, so trifling that it is necessary that three specimens of each kind should be sent. We can undertake to name only four varieties at a time, and these only when the above directions are observed.

PLANTS AND FLOWERS.

Earwigs on Chrysanthemums (W.).—Place a few small pots on sticks. Invert the pots, and put a little dry Moss inside. The earwigs will shelter here during daytime, and may be easily caught. Also put a few pieces of dry mat or sacking near the pots of the Chrysanthemums as further traps and shelter.

Lifting Arums (T.).—Lift the Callas at once, giving them a compost of rich loam and stable manure in equal parts, the latter to be well decayed. Use a pot 6 inches in diameter at top, and if the soil be rich and liquid-manure used when coming into blossom they will thrive well. We would stand them in a frame for a month or so after potting.

Dandelions on lawns (H. E.).—Cut the crown off the Dandelion, and cover the wounded part left in the ground with salt, or drop into it two or three drops of sulphuric acid. The remedy is a tedious one; but there is no better way. At the same time prevent the Dandelions in waste places near, if any, from seeding, as the seeds will travel with the wind for a long distance.

Roses for conservatory roof (F. Hand).—If you mean Marie Van Houtte, this would do for the conservatory roof, but would not cover the space so fast as a climbing Rose, of the type of Marshal Niel, etc. Purley and Robert Duncan are scarcely suitable, but would do on the back wall. Climbing Niphetos and W. A. Richardson would be two good fast-growing kinds.

Lifting and storing Gladioli (M. S.).—Early lifting is, we think, very injurious, for so long as the foliage is green the bulbs are gaining in size and weight. Lift the bulbs carefully with forks, cut off the tops a few inches from the bulb, and place in flat baskets, which should be carried to a cool underground cellar and spread on the cool floor. In this position they are as moist and cool as in the open ground, and at the same time are quite safe from frost.

Keeping Salvia patens (M. S.).—The plants should be lifted from the open ground, and after the soil has been well shaken off the roots be placed in fine dry soil in a greenhouse or in a cold-frame, and protected in such a way that frost does not reach them. In this way the roots keep better than when dried and put away in a shed or on a shelf. If your plants are in pots they should be cut down and be stood under a greenhouse stage till March. These, if brought into the light early in the year, will start into growth and the young shoots make fine cuttings, which may be planted out in spring.

Plants for shady garden (T.).—Try Gaillardia grandiflora, Delphiniums, Coreopsis grandiflora, Lupines, Yucca filifera, the Welsh Poppy (Meconopsis cambrica), Scabiosa caucasica, Double White Rocket, Pentstemon, Lily of the Valley, Christmas Roses, the Double Periwinkle. Many annuals will do fairly well in partial shade—Blue Cornflowers, White Antirrhinum, and Scarlet Zinnias, for instance—while the Biennial Columbinas and Foxgloves are seen at their best beneath over-shadowing boughs, and grow most naturally under such conditions.

Keeping Marguerites (Venus).—These are often lifted from the open before frost comes, but if you cannot secure a good ball of soil around the roots they often fail to survive. Water any plants you may think of lifting both before and after lifting, pot them carefully, and shade for a time. When established they may be stood with Pelargonium during the winter in a house with a temperature of about 45 degs. Do not over-water during the winter, and in the spring, if all goes well, they will soon produce plenty of cuttings, which can be rooted in the same way as Geraniums, etc.

Position for Christmas Roses (Breewood).—The soil best suited for these is a good fibrous loam, to which have been added some fibry peat, well rotted manure, and coarse sand, taking care that the site is well drained. A moist and sheltered situation, where the plants can obtain partial shade, such as the margin of a shrubbery, is best, but care should be taken to keep the roots of shrubs from exhausting the border. A top-dressing of well decayed manure and a little liquid-manure might be given during the growing season when the plants are making their leafage, as upon the size and substance of the leaves will depend the size of the flowers.

Montbretias, culture of (Eric).—Montbretias succeed best in a rather light, loamy compost, and require good drainage. The soil should be enriched with well decomposed manure, dug in deeply, and if a little leaf-mould and road grit be added all the better. The corms should be carefully lifted and sorted in February or March, according to the weather, and planted, the larger ones 3 inches apart, in rows 5 inches or 9 inches apart, the smaller ones being a trifle closer. This will allow of their

being mulched with spent Mushroom-manure or similar material to retain the moisture. Several waterings with liquid-manure are also beneficial. Montbretias require plenty of sunshine.

Roses attacked with orange-fungus (A Rose Lover).—Many Roses of the Hybrid Perpetual race are very prone to this fungus, but as it rarely appears until after the first blossoming, Rose growers do not pay much heed to it. It may be kept in check by carefully raking off dead leaves and burning them, also any prunings. A dressing of lime and soot in the soil is also beneficial if applied now. Probably your soil is a very hot one, and the Roses under such circumstances would benefit by transplanting, taking care to deeply dig the soil. In the spring the bushes should be severely pruned.

Mildew on Roses (Lady W.).—When mildew appears so late in the season, growers seldom pay much heed to it. It will not affect the welfare of the plants another year, but the spores remain on all decaying foliage, and will reappear again next season unless checked when first observed. Gather up all the fallen leaves and burn them. If any signs of mildew appear next spring, dissolve a ounce of sulphide of potassium in a gallon of hot water, then add enough cold water to make 3 gallons. Apply it as soon as you see the least trace of mildew with a syringe, taking care that the underside of the leaf is thoroughly wetted.

Growing bulbs in a glass bowl (J. B.).—Balls of the Chinese Sacred Lily succeed remarkably well in bowls if planted in the following manner: Place 1 inch or 2 inches of clean gravel or pebbles in the bottom of the bowl, and on this arrange the bulbs with care. Pour in sufficient water to cover the pebbles and also to rise about 4 inch up the bulbs. As this is absorbed make up the loss from time to time. When completed the bowl should be placed in a cupboard to encourage root-formation, returning it to the light when the green shoots appear. Crocuses and Hyacinths may be grown in damp Moss in a similar receptacle. Stand the bulbs on a layer of this material and surround them with the same, pressing them moderately firm into position.

Jasmine for winter-flowering (B. C. J.).—We presume that you refer to the Jasmine Souhai, a plant which requires a warm-house. The plants should be potted in April into a nice, well-landed compost of equal parts loam and peat, keeping them near the glass throughout the summer, admitting air in hot weather, and maintaining the atmosphere in a moist condition. Towards the latter end of the summer admit a more free circulation of air in order to well ripen the wood, and winter the plants in a temperature of 55 degs. to 60 degs.

Rose General Jacquemont not flowering (A Rose Lover).—Instead of allowing these long-growing to attain such a length, they could have their points pinched out when about 4 feet long, which would assist in the proper ripening of the wood. It is rarely this old Rose that flowers so satisfactorily, but you must not place much reliance on the growth formed late in the year, rather fostering the thin yet hard shoots, and shortening these to five or six eyes. It is just probable the soil is too rich. An application of lime would have a beneficial effect, and would be more helpful than manure. If the bushes have been in their present quarters three or four years, you might transplant them with much advantage.

Oleanders not opening their buds (B.).—In answer to this correspondent, I would suggest that May is much too early to turn them outside, unless "B." lives in the south or west, of which I have no experience. In Kent I never put them outside until after they have completed the flowering. I grew the double pink, single white, semi-double white, and apricot. The double pink is a direct descendant of the plant brought from Paris in 1800 by a member of my family, and the year before last (1899) it had almost as many heads of bloom as last year. The flowers are very sweet-scented, and so is the semi-double white, but the single white and the apricot have no scent. I keep my Oleanders in the greenhouse all the year until they have done blooming, then I stand them out in the sunniest place I can find and keep them well watered.—A. C. RICHMOND.

Making a lawn (J. Hillton).—Go over your present weedy lawn carefully and dig out all the bad weeds. Then pare off the surface, and when dry burn it, keeping the ashes to spread over the top when the grass seeds are sown. Give it a good dressing of the manure you have, all mixed together, and dig it in to a depth of 12 inches, taking care to well bury the manure. Let it lie rough till early in April, then break it down fine, and having well tined it, make it level, scatter the seeds from the fire heap, and sow thickly with good Grass seed (not that from a hayloft, which contains too many weeds). Rake this over again to incorporate the Grass seeds with the soil, then when dry roll with a fairly heavy roller. If there are any birds it may be well to stretch some black cotton at about 6 inches from the ground to prevent them destroying the seeds. When ready for cutting use the scythe until the Grass gets established, when you can use the mowing-machine, setting it fairly high for a time.

Planting Roses (Max Kirchmeyer).—In answer to your inquiries we have pleasure to reply as follows: 1, Gloire de Dijon and Marshal Niel planted this autumn would not give you many blossoms next year, for it should be your endeavour to induce them to form good buds, then could you expect a tolerable quantity of the following season. Plants established in pots planted out in the spring would give you some bloom, but we should advise the planting of ground plants this or next month. 2, No special manure is required when planting. The ground should be deeply dug, and some good farm-yard manure mixed with the soil. Manure from a cow-yard would be better than fresh manure from stables. 3, By all means plant the Roses for the arches this autumn. You can tie them to a good stake until the arches are placed in position. A few good Roses for the purpose are: Crimson Rambler, Euphrosyne, Felicite Perpetue, F. Mrs. Alice Tibert, Mme. de la Roche, Gloire de Dijon, Madame Marie, Indelicte, Rive d'Or, Carmine Pillar, Benne's Seedling, and Electra.

Select Cactus Dahlias (Dahlin).—It would be useless to give you the names of any of the new varieties of Cactus Dahlias of this year, as, however good, they will

FRUIT.

FIGS.

TO THE EDITOR OF "GARDENING ILLUSTRATED."

SIR,—I notice that there are no less than five queries and articles on "Fig-trees and their Culture" in the issue of October 11th. The general complaint is that Figs are by no means a certain crop. One thing is certain this year, and that is, that it is a bad season for them. As I live in S. Devon, where Fig-trees are treated like elder Apple-trees, and are a great deal larger, I may be able to help your querists a little. What I cannot understand is why you say the Brown Turkey is the best. The fruit is coarse, skin thick, colour uninviting, and size small. The Brunswick Fig is greatly to be preferred, as it is very delicate and sweet in flavour, the skin is thin, and the fruit is handsome, both in shape and colour, whilst the size makes it noticeable, well-grown fruit weighing about 8 oz. I also have a large white Fig, with pale pink flesh, and a grass-green one with white flesh. I do not know their names.

It is of but little use to try and grow Figs, such as I gather by hundreds from the big old trees, unless the grower can reproduce in a measure some of the conditions of their native habitat. Asia Minor, if not their home, is the ideal place for them, with bare, dry, strong soil and no rain during the growing and ripening periods, for Figs fruit three times a year in such a climate. Three crops are also gathered in Texas, U.S.A., and I think it is not unusual to gather two crops a year from old trees in the west of Cornwall. With me the trees also set a second crop, but fail to ripen it, January and February being far too damp and cold. Given soil and climate, Fig-trees only ask for one other thing for themselves and one from their owner. The first is to be left severely alone—no pruning, no "tying-in," no manure, no water, just a wholesome neglect. From their owner they demand patience. When the Fig-tree is young, say twenty-five years old, the fruit is dry and harsh. There is a reason for this, for it is when the trees are young that the seed is at its highest fertility; the "envelope" or pulp is but secondary. With age the tree ceases to set much fertile seed, so the "envelope" becomes fruit in our meaning of the word. As Fig-trees have a long life in front of them, they devote their childhood to growth. If a sapling is planted in ordinary soil and left unpruned for a quarter of a century, it will not have any weak or unproductive wood, for, in building up its branches it will have taken up all the too strong constituents of the soil, and by the time it is old enough to bear really good fruit the soil is poor and hard enough to prevent course growth, and the annual growth will be short-jointed, hard, and thick. E. E. Biggs asks about his Fig-trees bearing quantities of immature fruit. Young trees do this for a good many years before they have strength to push them to their full size. Six years ago I had some young Fig-trees turned out of pots,

in which they had been fruited under glass, yet, though they have set fruit each summer, it has not developed to full size, though each season it gets rather larger. I hope I shall not be misunderstood, and be thought to have made out that Fig-trees will only fruit when old. I mean they will only crop regularly, giving quantities of rich, luscious fruit of refined flavour when they are full-grown.

Fruiting under glass is quite a different matter; but if anyone were to pick one of my half-pound Brunswick Figs, hot with the sun, and eat it at once, and then try the best fruit grown on young trees under glass, he would note the difference. The first that can be seen externally of the future "Fig" is the minute fruit pushing through in the same way that a flower or leaf-bud does on, say, an Apple-tree. This will show "H. N. G." that his theory is wrong as to different sexes in Fig-trees. His so-called "males" are nothing but either barren trees or backward ones that need more time to develop. "Ficus" might have "variabilis" added to its name, from the difference of foliage. For indoor culture there are many far more valuable Figs than Brown Turkey or Brunswick. These are only for outdoor culture. A little Fig, called in the Southern States, U.S.A., "Sugar-drop," is exquisite. The flesh is nearly scarlet. The white, also purple, Ischia are also excellent.

Dartford, S. Devon.

A. BULLMAN.

STRAWBERRY CULTURE.

THERE are many people whose garden space is limited, and though they are able to change the ground on which they grow their vegetables, yet still, like myself, there is only one part they run set aside for this delicious fruit. My plants have been grown for years on the same piece of ground, and no fruit could be finer or more abundant. I have thirty rows, about 9 yards long, and every year ten rows are lifted, so that any bed is never more than three years old. A trench 2 feet deep is dug, and this soil is moved to the other end of the bed, and the bottom forked up. The old plants which have been removed, and any garden rubbish, such as decayed vegetables, Cabbage stalks, Pea haulm, Grass cuttings, in fact, anything to get it out of the way—is put at the bottom of this trench. Then the soil for the next trench is put on, so that the top soil of this year goes to the bottom on the rubbish, and so lies for three years, and so on till the bed is done, and the ground is manured on the top in the usual way going along. The runners are left on the other beds till well on in September, when they are carefully lifted with the earth and planted in rows 3 feet apart. These fruit next year, and if they have been properly lifted should never lose a leaf. It will be seen from this plan that when the third year comes round the bottom of the trench, from all this decayed vegetable matter, is quite new soil. I grow Royal Sovereign, but find it too soft in a wet season for the soil, which is a still better; it does well in a dry season. The best all-round kind for all seasons is Sir Joseph Paxton. It is large, well

flavoured, and an abundant cropper. From these thirty rows I have pulled this season 330 lb., and it has been one of the worst years for weather possible, and so for fruit. When I have all the best runners lifted and made the new bed, the edges of the rows in the other two beds are trimmed up with a spade, the runners left, dug in, and the ground left rough for the winter.

Rushleigh, N.B.

NOTES AND REPLIES.

Fruit-trees for garden.—I am just about to fill up the empty places in a garden belonging to a country house (which is now vacant) before the incoming tenant enters, and shall be much obliged if you will give me names of the six largest upright-growing gooseberries, names of the two largest Peaches ripening in August, names of four large Kitchen Apples for winter use as standard standards? When should Medlars be gathered?—W. THOMAS, DUNDEE.

[Very few Gooseberries, especially large ones, have erect growth, and nearly all are of spreading habit. Even if not so naturally, the weight of fruit of a good crop helps to bring the shoots out laterally. You will find, for your purpose, Lancashire Lad and Crown Bob, reds; Gunner, green; and Whitesmith, white; to be as good a selection as you can desire. You will find in Conker and Early Grossa Mignonne good Peaches for your purpose. Of kitchen Apples for winter use as standards have Waltham Abbey Seedling, Wollington, Newton Wonder, and Northern Greening. Medlar fruits should be allowed to hang into November before they are gathered, or otherwise they shrivel and have little flavour, when a few weeks later they become soft and are eatable. Spread the fruits out on a shelf thinly, so that the soft, ripe fruits can be picked out as they are ready. Your note came too late for immediate reply, as we go to press early. Get your planting done at once.]

Defoliating Vines too early a mistake.—Nowadays, when there is such a demand for cut flowers, more especially from November till May, many growers have to strain every nerve to keep up the supply. In gardens where the glass accommodation is small it is a choice of two evils—either keeping the Chrysanthemums, etc., in the open too long, or reducing the shoots and leafage of the Vines too much. I can remember, before this craze for large Chrysanthemum flowers began, how easy it was to rest fruit-trees in houses. I have noticed during the past decade that in many gardens there has been a falling off in the quality of Grapes, and I believe the practice of having to fill these structures early in the autumn with plants is responsible for much of it. It is no uncommon thing during September to go into vineeries where the leafage is quite green and see most of the shoots cut back to within two or three eyes of the main stem. This is unnatural, and cannot be productive of good. Recently I was in a garden where some of the finest Grapes in the country used to be grown. About ten years ago Chrysanthemums were taken up and the early cutting back of the Vines shoots began. From that date a gradual decline in the quality of the crop began.—J. CLIBBOK.

BANA-CHAMPAIGN

VEGETABLES.

LATE PEAS.

PEAS are equally valuable in autumn as in the earlier months of the year, and though greater skill is perhaps required to secure them late in the season, their culture is rendered much more easy now with the many late varieties we have. We now have a goodly number of sorts to select from, and these of sterling merit, so that it is possible from among them to choose one or more that will answer in most districts—at any rate, wherever the Pea can be grown in autumn. At one time late Peas were of very tall growth, which necessitated the employment of long sticks to support them; but in recent years raisers have given us varieties which do not exceed 4 feet and 5 feet in height, and some, such, for instance, as Sturdy, do not grow so tall as that. The greatest gain of all is in the improvement of quality that has been effected in late Peas, for we now have—to quote one instance—the splendid flavour and quality of the old No Plus Ultra combined with a much dwarfer habit of growth. In some gardens No Plus Ultra, however the gardener may try, does badly, yet when, for instance, such a variety as Autocrat is employed, which partakes largely of the foregoing variety, the results are satisfactory. The Pea just quoted is, in fact, such a fine autumn variety that if I were compelled to grow but one sort that would be my selection. Other old late varieties have also been used for the hybridising and raising of new sorts with excellent results, some of which will be mentioned below. As Autocrat has already been alluded to, this is, as many of your readers well know, a handsome dark green Pea; a very heavy cropper, pods

pois of this are similar to those of No Plus Ultra in shape, but longer, and the quality is first-rate when cooked. This, like the foregoing, lasts in good condition for a long period, and is not so subject to mildew as some are. Sturdy, already mentioned, grows 3 feet to

cannot be surpassed for table qualities. Goldfinder is another of the same class of Pea. Twenty years ago Walker's Perpetual Bearer was largely cultivated, and a very good Pea it is, and is still listed by some firms. It attains a height of 4 feet to 5 feet, and is a very heavy cropper. British Queen where it will succeed is very highly esteemed. This is a fine white Marrowfat of splendid flavour, growing to a height of 6 feet, and must be well supported. On the heavy soil I have to contend with it is but an indifferent success. Yorkshire Hero, a wrinkled Marrow, used formerly to meet with more favour than it does now for late work. This is similar to Veitch's Perfection, but rather later, while it is equally as prolific and fine flavoured. Champion of England is another fine prolific variety for late use, but, unfortunately, it does not do well in every garden. When the soil does suit it, and plenty of sticks may be had to support the robust haulm, there can be no better Pea grown. Fortyfold is considered by some to be superior to the last named, and is rather a taller grower. Captain Cuttle has been highly spoken of, and has received an A.M. from the R.H.S., but, not having grown it, I am not in a position to speak of its merits. Among the above enumerated I consider Autocrat, Sturdy, Late Queen, Michaelmas, No Plus Ultra, and Chelsoian to be the best half dozen Peas in cultivation. If six more were required I should add Omega, Magnum Bonum, Goldfinder, British Queen, Captain Cuttle, and Fortyfold or Champion of England. If British Queen will not succeed, substitute Yorkshire Hero or Walker's Perpetual Bearer for it.

CULTURE.—Peas generally require careful cultivation to bring out all their good qualities, and the late varieties more particularly so, otherwise success may be looked for in vain. The soil must be deeply worked and well manured for them, and two other details that need the greatest attention are the supplying of the roots with an abundance of water during

Pea Champion of England.

Pea Michaelmas.

4 feet in height, the haulm being much branched, and very productive. The Peas are dark green in colour, and deliciously flavoured when cooked. I have heard of this Pea not doing well in some places, but with me, on a heavy loamy soil, it was a great success, and, like Autocrat, continued to yield well high to the end of October. Late Queen is another desirable variety, from 3 feet to 4 feet in height. This bears large, handsome pods, and the Peas are of first-rate table quality. Perpetual has a fine constitution, and continues to yield long after many sorts sown with it are past. This attains the same height as the last named, as does also Magnum Bonum. This is most satisfactory this season, and has been unaffected by the drought. Another late Pea that should be given a trial by all who have to keep up a supply for as long as they can be had is named Michaelmas. It is of dwarf habit—a fact which will at once commend it to amateurs—is very prolific, and is, moreover, a good drought and mildew resister, and its qualities when prepared for table are unquestionable. I class this as being next to Autocrat and Sturdy a suitable Pea for small gardens. Laxton's Omega, although not so often grown now, is, all the same, an excellent dwarf-growing late kind, and previous to the introduction of Sturdy was a favourite with most cultivators. Among the taller growers No Plus Ultra stands pre-eminent, but, as has already been remarked, it does not always give satisfaction. However, where it will succeed no finer Pea can be grown, for it yields abundantly over a long season, and its

long and well filled, flavour all that can be wished for when cooked, and it continues to yield over a long period, even in a dry season. It grows about 4 feet high and the haulm branches well. Chelsoian is another first-rate late kind, but dwarf in habit, and grows to

Pea Veitch's Perfection.

periods of drought and placing a good mulching of litter on either side of the rows. Attention to these two important matters means the prolongation of the bearing period and the warding off to a great extent of mildew attacks. The best method of growing late Peas where time and labour will admit is in trenches prepared in the same manner as for Celery. Care must, however, be taken to place none but thoroughly decomposed manure in the bottom of the trenches for the roots to work into, as half-rotted manure is worse than useless. The

trenches, too, should be filled not nearer the ground level when returning the soil on the top of the manure than 3 inches to 4 inches. This will leave space for applying the mulching material and for flooding the roots with water whenever necessary without any running to waste. The site for late Peas should be free from shade of any description, and the rows should never stand nearer together than 6 feet apart, 12 feet being preferable, as light and air can then have free play on either side. The ground between the rows can in this case be cropped with some other vegetable, such as autumn Cauliflowers. A. W.

NOTES AND REPLIES:

Late Broad Beans.—These are useful in many places over a long season. Personally, I enjoy a dish, when nice and young, as much as Peas or Runner Beans, and I always endeavour to have them over a long period. I sow frequently, and this year I have had them till the middle of September. My late sowing is generally made by throwing a few seeds amongst the late Potato drills in the field before earthing the Potatoes up.—J. CROOK.

Cucumber disease.—I enclose you a small Cucumber grown in a cool greenhouse. I have a lot more the same, rotting at the flower. During the past two months I have had fruit on this same vine grow to a foot in length and then go off as enclosed one; but on the same plant I have had a fine lot of fruit grow to 17 inches and 18 inches in length without showing any such signs, and have a few now quite 13 inches with no such sign. Can you give me the reason? I formerly had a frame, and this is my first attempt in a greenhouse.—NOVICK.

[The blackened points of the small Cucumber fruits set on your plant show that they are severely affected by a fungoid disease, although its scientific appellation may not be easy to determine. No doubt this disease has been generated through the general absence of sun heat and low temperature that have so long prevailed, especially that yours is an unheated greenhouse. Damp settles on the flowers when there is an absence of heat to assist proper fertilisation, then as the plants grow the mould preys on them and soon kills them. You will do well to remove all your plants now, also all the soil in the beds, then give the house a severe fumigation by burning sulphur in it to create fumes of a powerful anti-fungoid nature. If the house be shut up after you have fumigated it, no trace of the fungus will be left. But to do this the house must be emptied of all plants, as the sulphur fumes are deadly.]

Vegetable Marrows.—The fruit and vegetable committee of the Royal Horticultural Society have invited the council of that body to hold in their gardens at Chiswick next year an extensive trial of Vegetable Marrows. Whilst it is known that there is an immense variety of what are called ornamental Gourds and Pumpkins or Squashes, the number of really edible Marrows seems not to be well understood. Probably when the trial is conducted at Chiswick it will be found that there are some 40 or 50 varieties, all of edible quality. Because of what may be described as market prescriptions, the general public seldom have the chance offered them to purchase or to taste Marrows in the best and freshest condition, as market fruits are nearly all of the long white or green varieties, and, as a rule, are cut too old and large. At the Temple Show last May a pretty green round Marrow, the name of which I forget, was exhibited, but it seemed to have in it some of the texture of the Ohio Squash, a delicious variety eaten young. Since then I have been able to taste this variety, and found its flesh to be much superior to that of the market varieties. We want not large fruited, but varieties that bear very freely. Such ones as Pen-y-byd, Hibbard's Cream, Moore's Prolific, and others are of this character, but somehow they are not widely grown, the popular favour being for the long fruited. We have to train the public taste in favour rather of smaller fruits cut young and cooked whole, even the rind not being removed. In that way the true merit and flavour of the fruits are strictly preserved. It is to be hoped that the Marrow trial at Chiswick, if the council sanction it and every useful variety be represented, will do something to educate the public at large in reference to Vegetable Marrow variety and excellence.—A. W.

PLANTS AND FLOWERS.

ROSES.

HYBRID PERPETUAL ROSE FRAU KARL DRUSCHKI.

This is probably the finest white Rose in cultivation. The growth of the plant is strong and sturdy, flowering at every shoot; and after the first flush is over it immediately makes a second growth, which in turn flowers abundantly, and with fine weather in late autumn even a third crop of blooms may be anticipated. The Rose is pure white, but in the very young bud state a slight splash of blush is noticed on the outside petals. This entirely disappears as the flower expands, and when in the three-quarter expanded form (the most perfect phase of its possible beauty) no Rose is so white or more exquisitely shaped. The petals are of great substance, consequently of good lasting power, ever growing larger and more rounded as the flower develops. The plant requires a little attention in the way of

then replant in November. It is extremely risky to move Roses when in full leaf, but doubtless the plants would not have suffered so much if heeled in as mentioned. We should advise you to cut back the current season's shoots at once to within about 6 inches or 9 inches of their base, and remove all foliage. In the spring a further slight shortening should take place.]

Rose Jeannie Dickson (H.P.).—The old and formerly popular Victor Verdier must submit to being ousted from our collection in favour of the above-named Rose. It is a splendid bold flower, huge petals, and of a most pleasing colour, rosy-pink with silvery shading. The petals, being so stout, can withstand rain to a greater degree than many Roses, and on this account it is useful. It is of a much better habit of growth than Victor Verdier, and it makes an excellent companion to vigorous H.P. Roses of the type of Mrs. John Laing, Ulrich Brunner, etc. I hope raisers will not go on sowing us scentless Roses, for, however splendid they are, they do not fully satisfy. Unfortunately, Jeannie

A fine white H.P. Rose—Frau Karl Druschki.

disbudding, as it is prone to flower almost too abundantly. The clusters of buds should be thinned in order that individual flowers may have sufficient room to open and develop without injuring each other.

This variety received an award of merit from the floral committee of the Royal Horticultural Society, London, when exhibited by Benjamin K. Cant and Sons, the Old Rose Gardens, Colchester.

NOTES AND REPLIES.

Roses moved in August.—Could you kindly advise me with regard to my Roses? I had to move in August to a new house. I took up a Margaret Dickson, Aug. Guinollesau, some Mosses, L'Idéal, a China Rose, a Crimson Rambler, and some others, the names of which I have lost. I dug them up very carefully and put them in a puddle of clay and water, and planted them in a day or two. The foliage of all of them withered almost immediately, and they look very badly. What ought I to do? Ought I cut them down or leave them till the spring? The stems still appear green and firm. I shall be very much obliged for some advice.—MRS. E. BROWN.

[The correct procedure would have been to heel in the plants under a north hedge or wall, at some time shortening back their growths,

Dickson must be classed among the fragrantless Roses. It strikes freely from cuttings, and even little yearling plants produce massive flowers. It is splendid for pot culture.—ROSA.

A good autumn blooming Rose.—Roses that blossom well in autumn are valuable, and, as an autumn bloomer, Heinrich Schultheis holds a foremost position. In a border I have standards of this kind, and at the end of September I counted from sixty to seventy blooms open or to open on one plant. The flowers open well, not being so full as those of some other kinds. It is a good grower with me, having clean glossy foliage and strong shoots, on which are often bunches of from three to seven blooms. Another recommendation is that it is not liable to mildew. My custom is to go over the plants in August, syringing with an insecticide, this preventing mildew attacking the foliage. This Rose has a lovely scent; I have a few blooms on my table as I am penning these lines, and the perfume is delicious. I often think too little attention is given to kinds that have this

GARDEN PESTS AND FRIENDS.

CUCUMBER AND MELON LEAF BLOTCH (CERCOSPORA MELONIS).

SEEN: the widespread destruction that has taken place in our market nurseries from this disease, the following article from the *Journal of the Board of Agriculture* will, we hope, prove useful to our readers:—

This fungus, although first observed and described as a new species so recently as 1896, has spread with remarkable rapidity, and at the present moment is the most destructive parasite with which the cultivator of Cucumbers and Melons has to contend. In several instances growers report an annual loss of £1,000, whereas others have had to abandon the cultivation of these plants owing to the repeated destruction of their entire stock, in places where the fungus has secured a firm foothold. The foliage is the part attacked. The first indication of the presence of the disease is the appearance of a few small, scattered, pale green spots on the upper surface of the leaf. The spots gradually increase in size and also in number, and often run together, gradually passing through grey to a brownish or ochraceous colour. If at this stage the upper surface of a diseased spot be examined with a pocket-lens, it will be seen to be covered with delicate upright brown threads, each bearing a conidium at its tip. This represents the fruiting portion of the fungus, the mycelium or hyphae being buried in the substance of the leaf. The minute conidia or reproductive bodies are carried from diseased to healthy leaves by currents of air, insects, clothing, etc., or by spraying, and if the leaf surface is moist such conidia germinate and the germ-tubes enter the tissues of the leaf directly. Very frequently a leaf becomes quite dry and crumbles to the ground within 24 hours of the first infection. Such dead fallen leaves are much more responsible for the rapid spread of the epidemic than are the conidia which pass directly from one leaf to another. When the dry fragments of a diseased leaf fall on damp earth, the mycelium present in the tissues quickly commences growth and forms an exceedingly delicate cobweb-like mycelium which runs on the surface of the soil and produces myriads of very minute conidia which are dispersed by currents of air, and infect the leaves in a manner similar to that of the larger conidia borne on the leaves. The mycelium in the soil originating from diseased fallen leaves continues to extend and produce conidia so long as the requisite conditions as to moisture and temperature are present. When these conditions fail, the mycelium passes into a resting condition, but readily assumes renewed activity when stimulated by returning moisture and heat. By this means the fungus survives from one season to another in the soil, and the disease is almost certain to recur year after year in a house that is once infected, unless the soil is thoroughly sterilised.

It is important to remember that the disease under consideration can only assume the proportions of a destructive epidemic when attacking plants grown under glass, and where a high temperature and an excess of moisture are present. Such conditions, accompanied by a deficiency of light, result in the production of "soft" foliage, and it is only such soft foliage that the fungus can attack. Experiments carried out at Kew prove that the fungus cannot inoculate leaves that have developed under "lights," or in the open air. Plants that are badly diseased, if removed to the open air produce new foliage, which remains perfectly healthy. The disease is entirely an artificial creation, rendered possible by the rushing mode of cultivation followed. The seed remains perfectly free from disease, hence there is no fear of its introduction from this source, and its sudden appearance in a new locality remained inexplicable until indicated by the following incident:—An establishment in Hertfordshire sending consignments of Cucumbers to Covent Garden Market, remained free from the disease until the commencement of the present season, when on one occasion some empty "flats" or packing boxes that had contained Cucumbers, sent from a place where the disease was known to be rampant, were by

mistake returned from Covent Garden to the Herts establishment, where from that date the disease appeared and is now practically beyond control. To test the possibility of this means of introducing the disease, an empty box that had contained diseased Cucumber leaves sent to Kew for determination, was placed over a young Vegetable Marrow plant that was growing under glass; within three days every leaf was destroyed by the disease. Another Marrow plant growing in the open and subjected to similar treatment did not contract the disease.

PREVENTIVE MEASURES.—If the foliage is fairly hard the disease cannot assume the dimensions of an epidemic, and even if it appears it can be kept well in hand by spraying. To accomplish this end a fair supply of air should be admitted so that the atmosphere is not constantly saturated with moisture. It is wise to spray in anticipation of the disease, using a solution of potassium sulphide—2 oz. to 3 gallons of water, adding 2 oz. of soft-soap. It is very important that the under surface of the leaves be thoroughly wetted with the solution. If the disease is present, the soil should also be drenched with the solution. Diseased leaves should be removed and burned before they decay and fall to the ground. After a diseased crop has been removed the soil should be thoroughly drenched with a solution of "Jeyes' Fluid" in the proportion of an ounce to a gallon of rain-water. As to the danger of infection arising from spores being conveyed in packing cases as recorded above, no suggestions can be offered; nevertheless, the matter is one claiming the attention of cultivators, and as the wholesale mixing up of such hampers appears to be the rule rather than the exception, it is probable that many diseases other than the one under consideration have by this means been first introduced to a new locality.

NOTES AND REPLIES.

Aphides on Birch-tree.—I shall be obliged if you can tell me what is the matter with the Birch-tree in my garden? It appears to be in some way blighted, and has leaved in a very poor manner this year. As it is about 50 feet in height and a great ornament to the garden, I am anxious not to lose it.—F. W. DAVIDSON.

[The leaves of your Birch-tree appear to have been attacked by one of the aphides, some of the dead skins of which are still adhering to them. They usually live on the under sides of the leaves, so that the honey-dew which they secrete falls on the upper surfaces of the leaves below them. Several kinds of fungi grow in this honeydew, which gives the blackish appearance to the leaves. Is your tree in such a position that it is under the influence of the smoke from the railway works?—(G. S. S.)

Insects in garden.—What are these insects? Are they likely to be injurious to plants? How should they be got rid of? They were found in holes in a wall and floor of outhouse where there had been a Mushroom-bed.—F. E. B.

[The small worms you enclose are quite likely to injure plants. They belong to the family Enchytraeidae, which is nearly allied to the earthworms. Certain members of this family are certainly very destructive to plants, but the species are so difficult to distinguish one from the other that I cannot be sure if the species you have found is an injurious one or not, but I should certainly act as if it were. I do not find any record of any experiments having been made with a view to destroying them. I made one on some that were sent me a few months ago. I soaked the soil they were in with lime-water, and found that they all died within five minutes. If you were to water the floor of your outhouse with boiling water, a solution of carbolic acid, lime-water, or any of the weed-killers, so that the liquid soaked into the cracks where the worms are, you would no doubt kill them. The holes in the wall should be syringed with one of the above. These worms would not travel far, but might be carried about.—(G. S. S.)

Insects injuring plants (M. J. K.).—When you speak of centipedes injuring your plants, I suppose you mean snake-millipedes, for centipedes are carnivorous, and do not injure plants in any way. The snake millipedes are very injurious to plants, as they generally attack the roots just below the collar of the plant, and one species, the spotted snake millipede, is also

very fond of ripe Strawberries, and may at times be found feeding on them in large numbers. They are very difficult creatures to destroy, as their skins are so horny that it is almost impossible to get any insecticide to have any effect on them. They may be trapped by burying small slices of Potatoes, Turnip, Carrot, or Mangold near the plants they are attacking. Stick a small wooden skewer into each so as to be able to find it easily, and examine the baits every morning. The snake millipedes may be distinguished from the centipedes by the rate at which they move; the former, in spite of their very numerous legs, travel very slowly, while the centipedes scurry off with great rapidity when disturbed.—G. S. S.

Growth on Rose-tree.—What is the nature of this growth found on two different Penzance Briers? Would it be injurious to the trees? It is the first year of the Brier here, and it has done well.—CORSWOLD.

[The growths you find on the Briers are caused by the grubs of one of the gall flies—the Rose gall-fly (*Rhodites rosae*). This insect, as a rule, only attacks Briers. It seldom is the cause of any real injury to the plant, but I have seen wild Roses growing in unfavourable positions so covered with it that the plants were nearly dead. These galls grow at times considerably larger than your specimens, and have been found 3 inches in diameter. If you cut one open you will find that it contains a number of cells, in each of which is either a grub or a gall-fly, according to the time of year. The parent gall-fly lays her eggs in the stems, and sometimes in the stalks of the leaves. When the grubs hatch they begin feeding on the tissues of the plant, this setting up a very peculiar growth, which assumes the form of a ball of Moss, the centre of which is more or less woody, and contains a number of cells. These galls are commonly known by the name of "Robins' pincushions" or "Bedeguars." Formerly they, as well as many much more nauseous curiosities, were used in medicine, but I do not know for what complaints they were supposed to be beneficial. The gall-flies are small, four-winged insects, belonging to the same family as those which form the different kinds of galls on the Oaks. Should this insect increase to such an extent as to become a nuisance, it may be destroyed by cutting off the galls and burning them.—G. S. S.]

Caterpillars on Gooseberry-bushes.—Will you kindly name the enclosed caterpillars? They came in spring upon my Gooseberry-bushes, then upon Red and White Currants, but not Black, and stripped off every leaf. They have just now reappeared on the Gooseberries. I never before always come when an east wind has been blowing for several days. They do not appear to turn into any butterfly or moth, but simply disappear when a bush is stripped; but I notice tiny black specks on the leaves, which I imagine are their eggs. Please tell me what butterfly or moth lays these eggs, also what I can do to clear my garden of these pests? Would it be advisable to lift all the Gooseberries, and dig and lime the ground before replanting them? Also, is there any wash or mixture I could paint or spray the trees with?—W. E. W.

[The caterpillars that you found injuring your Gooseberry and Currant bushes are the grubs of the "Gooseberry saw-fly" (*Nematodes ribesii*). It is, unfortunately, a very common pest. That the pests always appear with an east wind must be merely a coincidence, for they are hatched from eggs laid by the female saw-fly several days before and are so small at first that they are not likely to be noticed for a few days. There are two or more broods of this insect during the season. Those that you find now are the last brood. When they are full-grown they will drop to the ground and bury themselves about 2 inches or 3 inches from the surface and become chrysalides, each within a small cocoon. The most effectual way of destroying these insects is during the winter to remove about 3 inches of the soil from beneath the bushes—this soil will contain the cocoons—and burn or bury it not less than 1 foot below the surface. If this is done properly your bushes should not be infested again next year, unless the saw-flies from a neighbour's garden visit you. If they do, and your bushes are attacked next year, as soon as you are aware of the presence of the grubs spray the leaves on both sides with paraffin emulsion, or any insecticide containing soft-soap. If the fruit is nearly large enough for cooking and is to be used for that purpose, you cannot use any insecticide for fear of giving it an unpleasant flavour or making it

unwholesome, in which case it is a good thing to give the bush a good jarring shake, which will bring many to the ground, where they may be easily disposed of. The back of a spade makes a very handy implement, or they may be picked off by hand.—G. S. S.]

INDOOR PLANTS.

DOUBLE BEGONIA DOROTHY HARDWICK.

The double-flowered Tuberous Begonia Dorothy Hardwick is one of the loveliest things in its own way yet seen. It was raised and sent out some three years ago by my friend, the Rev. Edwin Lascelles, rector of Newton St. Loe, near Bristol, who has done far more for the improvement of these beautiful autumn-blooming ornaments of the greenhouse than any of the many raisers who have tried their hand at them. Its colour is

part leaf soil, the remaining portion consisting of fibrous yellow loam. Sufficient rough sand should be added to retain the compost in an open and porous state. Turn the plants out of the pots, and after removing all decayed matter replace the plants into the newly prepared pots, then work the new compost carefully among the roots, making it moderately firm. The surface may be banked towards the centre with Sphagnum Moss. Water thoroughly as soon as repotting is complete and replace in a moist position of the stove. Shade from the direct rays of the sun and syringe freely in bright weather. Once in two years should be sufficiently often to repot the plants. They produce their flowers during the early summer. When autumn arrives these plants complete their growth and remain practically in a dormant stage for some months. During this period the plants will be benefited by removal to a drier and rather more airy position than the stove, but if they cannot be conveniently

shards to retain the compost in an open and porous condition. All the old compost and decaying matter should be removed, and the new compost must be pressed moderately firm about the roots and base of the plant, filling to the depth of about an inch below the rim with the compost, and the remaining space with chopped living Sphagnum Moss, mounding slightly to the centre. Water, wherever leaf-soil is used in the cultivation of Orchids, must be applied with care, the leaves absorbing and retaining a quantity of moisture from the atmosphere. The plants will not require anything like the quantity of water that was necessary when the compost of peat and Sphagnum Moss in equal portions was used. I find it best to give the plants a thorough watering as soon as they have been repotted, using rain-water and pouring it through a moderately coarse rose on the water-can. Sprinkling the surface of the Moss when it appears dry is all the water that will be required afterwards. Spray the plants

Double Begonia Dorothy Hardwick. From a photograph by G. A. Champion.

the most delicate shade of rosy-blush, its petals have a most beautifully frilled edge, and it is an exceedingly free and continuous bloomer. W. E. GUMBLETON,

NOTES AND REPLIES.

Good scarlet Pelargoniums.—Will you kindly use the largest-flowered scarlet (*Pelargonium* Zonal), not violet-veined or orange-scarlet, but pure scarlet and single?—M. J. K.

Very large single-flowered scarlet Zonal Pelargoniums.—Lord Hopetoun, Lord Strathcona, Nicholas II, and the Sirdar, while Hail Caine, soft rosy-scarlet, is a particularly fine variety.]

Anthurium Scherzerianum (*Sandl. & Buckley*).—This is an aroid and not an orchid. Through the spring and summer months this requires stove temperature. Repotting, where necessary, should be done in early spring. The pots used should not be too large, and filled to one-third their depth with clean broken potsherds. The compost should consist of fibrous peat, two parts, one

removed, the plants should be kept drier at the roots, only sufficient moisture being given to retain the leaves in their normal condition and prevent the surface Moss from decaying. With the return of spring renewed vitality will appear. The plants should then be more liberally treated.—H. J. C.

Maxillaria grandiflora.—I have just had some plants of this given me, and shall be glad if you will kindly give me a few hints as to its cultivation, heat required, best compost for it, etc.?—SAMUEL C. BUCKLEY.

[There is no more suitable Orchid for cold or Odontoglossum house cultivation than this species. It is one of the earliest plants to manage, even when grown in a cold greenhouse with only sufficient heat to exclude frost. It is best accommodated in pots, which should be filled to one-third their depth with chopped Bracken-roots, such as will be discarded when picking the peat. The potting compost should consist of good (Oak) leaf-soil, two parts to one of fibrous peat, with a little chopped Sphagnum, and sufficient rough sand or finely broken pot-

at intervals of about once in fortnight with some insecticide, to keep them from all kinds of insect pests to which the plants are subject. The plants should be placed at the cool end of the house or in a position where they have constant moisture about them. *Maxillaria grandiflora* requires a liberal amount of air.—H. J. C.]

Pentas carnea.—In a greenhouse the other day some plants of *Pentas carnea* were being staked and tied up preparatory to winter blooming. Though liking heat, one may grow this plant in a moderately warm temperature, and its pale pink blossoms are very acceptable. It likes a compost of light loam, leaf-mould and sand, plenty of moisture when in full growth, and, if brought on in succession, plants may be had in flower at almost any time of the year. Cuttings of half-ripened wood covered by a bell-glass strike freely in a little bottom-heat. Although an easy subject, few people grow it now. It is one of our best soft-growing shrubs, and needs frequent stopping to maintain a bushy habit.—TOWNSMAN.

OUTDOOR PLANTS.

ERIGERON (FLEA-BANK).

MICHAELMAS Daisy-like plants of dwarf growth, similar in general appearance, and having pink or purple flowers with yellow centre. They flourish in any garden soil, but a few of them are seen to best advantage in the rock garden. The following are among the best in the family:—

E. AFRANIMUS. This, when doing well, is not more than 2 inches high. In the rock

Erigeron multifloratus.

garden or in the front of the border the plants should be in groups. Slugs are partial to this kind during the winter, and will speedily devour it if left to itself. The species is of close tufted growth after the manner of the alpine Starwort, while the growth is not so abundant as to permit of frequent division. It may be raised freely from seeds, which if sown at intervals during the spring months, will prolong the flowering period.

E. PAUCIFLORUS.—This grows about 2 feet high, and bears masses of rosy-purple heads of flowers. These are not large, but their abundance produces a very pretty effect in the border.

E. GLABRILIS.—A free-growing species from the North United States, bearing a cluster of purple flower-heads on stems about 15 inches high. It is a useful border kind, readily distinguished by the numerous florets composing the ray encircling a yellow disc.

E. GLAUCUS (syn., *Aster bonariensis*).—This is one of the best of this genus. The species usually sold under the above name is a form of *E. serotinus*. For the rock-garden this is one of the finest of all. The ray florets are much broader than usual, as also the flower-heads. It is a vigorous sub-shrubby evergreen species with free-spreading branched habit, and when well established will attain 18 inches high and 2 feet across. The sturdy lilac-purple flower-heads appear on leafy stems a little above the rosettes of leaves. It is an easily grown species, and may be increased freely from cuttings or division when large enough.

E. GRANDIFLORUS.—This is an excellent species, with dwarf evergreen tufts close upon the earth, after the manner of the alpine Aster. The flower-heads are large and of a purple shade, and it does best in warm soils. There is a pure white form of this plant which is usually regarded as synonymous with the white of the alpine Starwort (*Aster alpinus albus*). It certainly somewhat resembles this in growth and in its large handsome flower-heads.

E. MACRANTHUS.—A North American species, attaining about 18 inches high, and producing

freely its large violet-purple heads. It is a mid-summer-flowering kind.

E. MICHONATUS (syn., *Vittadenia triloba*).—This pretty little plant with its abundance of Daisy-like blossoms forms patches 2 feet across that in late summer and early autumn are smothered with vari-coloured pink and white blossoms. The patches of leaves are quite close to the soil, while the flower stems attain to 6 inches or 8 inches high.

E. MULTIFLORATUS.—This differs from the rest of the family in the great number of its ray florets, which are of a purplish shade and the disc yellow. The plant grows from 1 foot to 2 feet high.

E. ROYLEI.—A dwarf growing and tufted species also from the Himalayas, with handsome flower-heads of a bluish purple hue, each about 2 inches across, and disposed in a loose corymb. It is about 9 inches high, and an excellent plant for the rock-garden in good deep soil.

E. SEROTINUS.—This is the best known and most widely grown of the whole family of the Flea hares. The plant, from its easy culture and the quantity of blossoms that it produces for months in succession, is well deserving of the popularity it enjoys. A variety known as *E. s. superbus*, or *splendens*, as it is sometimes called, is of a lighter hue, and is perhaps the most free flowering of this group. Another distinct kind, *E. s. glaucus*, referred to in lists as a possible hybrid, is doubtless but a good form of the plant under notice, the florets of the ray deep purple. The foliage in this is of a glaucous grey tint, the plant being of the same height and equally free flowering. The typical species inhabits North-Western America, and has long been known to cultivation.

INCREASING THE CLEMATIS.

What is the correct time to take cuttings of the Clematis, and what is the mode of procedure? An answer in the columns of your valuable journal will greatly oblige.—
T. MAWELL.

[The usual stock on which the different varieties of Clematis are grafted is the roots of Clematis Vitalba (Traveller's Joy). The operation is generally carried out in the following manner: Assuming that the plants are in pots, a plant or two is towards the end of February taken into the greenhouse, where they at once start into growth, and when the new shoots are firm enough grafting can be begun. Each shoot will form more than one scion, as the two opposite leaves and the piece of stem below are quite sufficient for one graft. The string-like, fleshy roots are used as stocks, each bit that is sufficiently stout to take the graft being available. Do not graft on a mutilated root—that is to say, one with the lower portion cut off—as all the fibrous parts must be retained. The lower portion of the scion must be fashioned like a wedge with a keen knife, and the stock split sufficiently far to receive it. It is then tied securely in its place with soft grafting cotton. Then each one is potted singly into a small pot at such a depth that the point of union is just covered with the soil. In order that this can be carried out, the long, string-like root is twisted round the pot till it is at the required depth. Then they are plunged into a close propagating-case with a gentle bottom-heat, and will quickly become established. A good deal of the success or otherwise of the operation will depend upon the after treatment, such as shading from sunshine and preventing the young succulent leaves from damping off. This decay which sometimes sets in is caused by the air of the propagating-case being too much charged with moisture; hence the lights should be raised a little at times to allow it to escape, but at the same time the grafted plants must be kept close enough to prevent shrivelling. A little practice and close observation will show better than words how this is to be done. When a union is effected, which will be seen by the plants starting into growth, air must be gradually given till the plants are inured to full exposure. The roots should be taken into the propagating-house a few days before they are required for grafting. While this details the practice generally employed, grafting of the shoots produced out-of-doors may be done later in the season. For this, while a close propagating-case is (as with the others) needed, bottom-heat can be dispensed with. The roots intended for stocks should be lifted while still

dormant and laid in a cool, shady border till wanted. Owing to the fact that grafted plants of Clematis sometimes die off in an unaccountable manner, attention has been directed to other means of propagating this beautiful class of plants.

Cuttings and layers have been resorted to, and each has its advocates. For cuttings select the young shoots when about 4 inches long with a small heel of the old wood, and insert them around the edges of clean, well-drained pots in sandy soil. Then place them in a close propagating case in a warm greenhouse, where, with the treatment given to the general run of soft-wooded cuttings, such as Fuchsias, Heliotropes, etc., they will soon root. In potting them off, the extremely brittle nature of the young roots must be borne in mind. Layering may be carried out now by burying one or two of the long, flexible shoots that are most conveniently situated for the purpose. The stem should be lightly tongued below each joint. Do not bury the joint too deeply, as it is better to leave a depression in the soil, which may be filled up after the young shoots have made sufficient headway to elevate the leaves above the surface of the soil.]

TREATMENT OF VARIOUS LILIES.

Kindly say what soil and treatment are best for *Lilium candidum*, *L. auratum*, Tiger Lilies, and *Parsons' Favorite* for planting outside in border? Also, how deep the bulbs should be planted? And if left in the ground for long, or when taken up and dried, and for how long.—
GARDENER.

[*Lilium candidum* succeeds best in a well-drained, rather sandy loam. The bulbs should, if possible, be planted in their permanent quarters before August has left us, as they root quickly. They should be planted at such a depth that there is from 2 inches to 3 inches of soil above the topmost portion of the bulb. After this no lifting will be necessary, as unless this Lily is disturbed the better, for when in good condition it will stand in one spot and flower well year after year. *Lilium auratum* needs a soil of about one half sandy peat and the other half loam, though under any conditions it is most erratic in its behaviour. Being a peat lover, it is often planted in Rhododendron beds, the Rhododendron serving to protect the young shoots from spring frosts and cold winds. The should be planted at about the same depth as those of *Lilium candidum*. For all this, can never depend upon *L. auratum*, and it occasionally be found to thrive under conditions very different from those above given. Do not lift the bulbs in the winter, as they are liable to disturbance when once established. *Lilium tigrinum* (the Tiger Lily) is best treated more as recommended for *L. candidum*. Those

Erigeron aurantiacus.

the bulbs are considerably smaller than those of this last named species, they may be planted at much the same depth. *Tigridia Parsonis* a more tender subject, that needs to be lifted in the autumn and stored in a spot free from frost, and also from mice, as these last are

ary fond of the bulbs, and will soon destroy a considerable number. The bulbs should be treated like those of the *Gladiolus*—that is, lifted in the autumn, as the leaves show signs of going to rest, and laid on a sunny shelf in order to thoroughly ripen them. After this they are better laid in dry sand, as if kept out long they are apt to shrivel, and placed here just free from frost, but nothing more, otherwise if kept warm they will start too early. A warm, sheltered border suits this best, and the bulbs may be planted early in April unless extreme weather prevails. Put the bulbs 3 inches deep.]

NOTES FROM AN IRISH GARDEN.

On the first week of October, it is pleasant to enjoy such things as Dahlias unharmed by frost. The pretty, free-flowering variety *Admiration*—neither show nor pompone sometimes comes all scarlet; Mrs. Langtry varies. *Aeomoae japonica* is still well in flower. It is almost as easily affected by frost as *habitas*. This being a rather late locality, the hocks are still in their prime, some having a foot or more of their stems in bud. The ones are green and healthy in the flowering stage, and the blooms are the size I have seen for years, reminding me of their former beauty. White or primrose-coloured blossoms have a fine appearance among the reds. Sunflowers are blossoming, the flowers being borne by *Soleil d'Or*. *Uvaria glaucescens* still sends up its spikes of scarlet and yellow tubular blossoms. Though *Phloxes* are mostly over, those growing in a little shade are yet fresh and beautiful. Of light-eyed varieties, especially of a good red shade, over a foot high, above three dozen bunches of flowers. Sprays of little yellow blossoms of *Solidago* pretty for variety's sake. There are yet a few fresh blossoms on little branches of *Illea The Pearl*. *Chrysanthemum maximum* has a flower yet, but this plant is too like the late-flowering species of the fields to be given much space. *C. uliginosum*, in bud white, has more of the character of a flower than it, and is a useful subject late. *Camulas* may be seen giving blossoms yet, as *C. sicifolia*, *calycanthema*, *C. rotundifolia*, and *C. Medium*, which reminds me how beautiful in its day a bed was of some twenty species, in colours and degrees of doubleness. *Clasping Peas* have grown too much to leaf this year. *Eupatorium ageratoides* is in flower. *Yulais lutea* or its seedlings are fresh in age and flowering freely. Perennial *Cornifers*, red, white, and blue varieties, are still in bloom. *Lychnis diurna* fl. pl. *Flos-cuculi*, *Hypericum*, *Prinnella grandiflora*, *Linum bonense*, and a yellow *Lysimachia* are giving about their last blossoms. The last two are very beautiful in their day. Perennial

are in flower. The decurved, small-flowering branches of the so-called French Southern-wood (*Artemisia*) are singular; the white foliage of the plant makes it rather pretty; its scent is less powerful than in the common kind. Ripe fruit is on *Digitalis lutea*. This

margined *C. p. integrifolia* is pretty. *Convolvulus minor*, blue, purple-blue, white, and pink, with a deep zone round the eye, are all pretty. Its twining relative, the Morning Glory, is also an old acquaintance. *Nasturtiums*, *Chrysanthemaums*, an annual *Silene* (like *S. orientalis* a little), double orange *Eschscholtzia*, and *Calendula* in variety may also be mentioned. *Cornflower* will keep blossoming until killed by frost. There are now, besides the blue shades of this useful annual, so many other colours, from red to white, or from blue to white, or wine coloured to very dark, which render it all the more useful and pleasing. Sweet Peas are blossoming, weather of a favourable character having developed fresh growth in the plants. The pink coloured *Hawkweed* is rather pretty—more so than the white; it is an old-fashioned annual. This is a time of the year that some variegated plants have nice foliage developed. Hardy Ferns have given good fronds this year.

Erigeron macranthus.

Foxglove has its stem during growth always bent down at the top—unlike our common one, which is erect. The yellowish, tubular, brown-spotted blossoms, hairy within, are rather pretty. I once grew a small-flowered, brownish coloured species—*Grecian*, I think. *Montbretia* is at its best. A sweet-scented *Cyclamen* has not long gone out of bloom. *Colchicums* have been in flower for some time, though more are coming up—white, lilac, rose, and double kinds. The common *C. tessellatum* sometimes has seven divisions to the flower.

It is interesting to see these and *Crocuses* proper pushing up out of the bare earth without the usual accompaniment of leaves. *Muscari conicum*, Heavenly blue, has leaves now more than 6 inches high, and a long time will elapse before its blossoms develop. A fine *Crocus* is *C. speciosus*, usually the first of the autumnal kinds to appear. Its blossoms are long, of a good blue, and elegantly lined internally, and it has an ornamental, much-branched, scarlet stigma. *Daisies* have renewed themselves, and are giving blossoms. A common *Wallflower* has a bunch of blossoms open, and the scent makes one think of other spring flowers now dormant. One *Snow-drop Anemone* has a young silver flower-bud drooping from out its three-leaved involucre. A plant of *Myosotis dissitiflora* is also blossoming. Some annuals have yet a little of the showy element in them. *Shirley Poppies* keep opening their scarlet, pink, white, or edged blossoms. Large plants of the double French *Poppies*, growing in rich soil, and lying down, are sending up numbers of blossoms, red self margined, or double pink with white margins, and the best—*Godetia*, *Clarkia elegans* pl. and *C. pulchella* are in flower. The white margin, and as the leaf is flat the colours are well seen. The silver tricolor *Mrs. T. Dickson* makes also a neat variegated plant, its convex leaves also displaying well the pink inside the broad white margin. A tricolor *Fuchsia* is in good leaf now; it is almost as well not to let its red blossoms come to perfection. It is late for the rose-coloured *Pheacomena* to be flowering when others are over almost, including *Wave of Life*. I still like to grow *Rose of Castille*.

IRISH READER.

Erigeron glaucus.

Erigeron speciosus.

stems of the Nova Anglia type are beginning to bloom, and rather smaller-flowered kinds. Planted in shelter, these will not be killed by the earliest frosts. Some of the dwarf, creeping-rooted kinds are not worth growing, though *Staticelatifolia* and *Helenium autumnale*

soms. Large plants of the double French *Poppies*, growing in rich soil, and lying down, are sending up numbers of blossoms, red self margined, or double pink with white margins, and the best—*Godetia*, *Clarkia elegans* pl. and *C. pulchella* are in flower. The white

Arctotis grandis.—As some of your readers are asking about the cultivation of this plant, I beg to say that I have grown it very successfully this year. The seed was sown in a hotbed in April and planted out in June, URBANA-CHAMPAIGN

under the east wall of a greenhouse, in rather a dry border. It has flowered profusely all the summer, and I have to-day (October 11) gathered a large bunch which, though the flowers were nearly closed when cut, have opened in a sunny window.—G., Leamington.

NOTES AND REPLIES.

Date Palm seeds germinating in the open air.—On October 2nd, while seeding a bed of Carnations, I found three seedling Date Palms, about 1½ inches high, with roots 4 inches long. The bed is sheltered from the north by a wall. The Date stones had evidently come from the rubbish-heap amongst some leaf-mould. Is it not unusual for Palms to grow from the seed in the open ground, with nothing to keep them warm?—TALBOT, Houston.

The Californian Fuchsia (Zauschneria californica) not flowering.—I have had a plant of this for about four years, planted in light, dry soil, facing south, sheltered from the north by a clump of Pampas Grass, and exposed all day to the sun. It increases in size and throws up stems annually 15 inches or more in height, but has never flowered. Can you kindly let me know what is wrong and how to make it bloom?—N. BROWN.

[This is a somewhat enigmatic plant, often refusing to bloom in soils and situations seemingly well suited to it, and again blooming freely in a flat bed of damp, heavy loam, which one would imagine quite unsuited to it. Perhaps the best position for this plant is a sunny spot in the rock-garden, in a mixture of sandy-loam. We have seen it growing freely and blooming profusely when planted between the stones of a retaining wall. In your case we should advise its removal to a more elevated and sunnier position into poor soil, while a restricted root-run might also tend to induce it to flower.]

Plants for border.—Please advise as to suitable plants (perennials) for shrubby border, aspect south-east. The border has large Elm-trees in close vicinity, which take a good deal out of the soil. Would *R. rugosa* or any varieties of Broom flourish under these conditions? I want to get a bright effect.—E. M.

[There are many things you may plant in such a border—Lupins, seedling Delphiniums, *Bocconia cordata*, *Pyrethrum uliginosum*, *Helianthus Miss Mellish*, *H. multiflorus maximus*, *Anemone japonica alba*, *Michaelmas-Daisies*, any of the Flag Irises, many *Campanulas*, especially *C. latifolia*, *C. grandis*, *C. lactiflora*, etc., *Rudbeckia Golden Glow*, *Paeonia officinalis fl. pl.*, a group or two of *Eremurus robustus*, such *Lilium as umbellatum*, *croceum*, *Martagon candidum*, *Iris sibirica* in variety, *Achillea Eupatorium*, *Acanthus mollis*, *Asphodelus*, *Helenium nudiflorum*, red and white Perennial Pea, Oriental Poppies, *Bupthalmum speciosum*, *Polygonum cuscutatum*, etc. *Rosa rugosa*, and such things as Brooms, *Forsythia suspensa*, could be planted as far as possible from the tree roots, which you may probably discourage by opening at some distance off a trench and cutting off with a spade all of a small, fibrous nature.]

Lilium auratum decaying.—Will you kindly tell me why my *Lilium auratum* bulbs rot or become diseased on the outer layers, so that I have to get fresh ones every year? Is there a cure for it, and what soil is best to pot them in?—SCOTT R. ADER.

[If your Lily bulbs only decayed on the outer scales of the bulbs there would be no need for renewing the stock each year. It is, however, clear that something more than this takes place, and we doubt not it is the old and frequently ventilated cause of no basal roots having been produced since the planting. These Lilies mature quite in midsummer in Japan, and, as is natural with not a few Lilies besides this one, the new roots—i.e., the basal roots already referred to—are produced at once. Then at lifting time, and in process of preparation for shipment to this and other countries, the bulbs are denuded of all their roots, chiefly, however, to facilitate packing. As there is but one series of main basal roots produced each year, it follows the bulbs arrive in this country minus the very essential to a permanent existence—i.e., main roots. In these circumstances the ultimate growth and subsequent flowering, if any, are wholly dependent on the stem roots that form in a great mass immediately above the bulb. Meanwhile the bulb has more or less exhausted itself in the output of the stem, and the bulb, incapable of gathering support by the natural process of roots from the soil, frequently collapses at the most critical time—viz., flowering. It is this state of things so frequently occurring in midsummer that is often referred to as "rotting."

whereas the true cause is as stated. This, however, does not occur to the amateur, who is often deceived by the great mass of stem roots near the surface, and considers the plant to be well rooted in consequence. We have planted this Lily by the acre in the hope of securing enough to form the nucleus for a home-grown stock, but the few surviving bulbs were so crippled as to never recover fully, and gradually dwindled away. At the present time in a small plantation there is a solitary bulb remaining of what was planted two years ago. As yet no flower has been produced, but this season there are two stems, which afford some proof of active basal roots below. This plant will be allowed to remain, and in time it may recover. A good clump of established *L. auratum* is always worth looking at, but such is rare. Indeed, we are strongly of opinion the bulbs of this species do not arrive in so good condition as formerly, and, remembering that shiploads reach London each year, the loss must be enormous. The only cure is the invention of a method of packing whereby the roots can be preserved to the bulb intact. When this is accomplished good clumps of these Lilies will be frequent in our gardens, but not till then.]

A ROCK BORDER.

The border shown in the illustration has only been made two years, and was converted into a

Rock border against a wall. From a photograph sent by Mrs. Hughes, Dabholin, Co. Down.

rock garden as it was a failure as an ordinary border, being too much shaded and having had soil. I was making a croquet court, and had the surplus soil placed here, leaving some parts rather low and flat, and raising others considerably. These latter I made rather stony, and planted things which require good drainage, while those which like moisture I kept below. The border is never without bloom from the time the first Aconite comes out in the beginning of January till the last Autumn Crocus and Colchicum die away in December. Of course, spring is its best time; then it is a mass of Primroses of various sorts, Polyanthus, Tulips, alpine Anemone, *Anemone nemorosa*, *Auriella*, particularly the bright yellow, which is most effective, *Hepatica*, Rock Cress, purple, mauve, and reddish Aubrietins, *Alyssum*, *Arenarin*, which covers many of the stones, and is a mass of little starry white flowers, and many other plants.

M. H.

Yucca.—I have a *Yucca*, obtained in May last by removal from a neighbouring lawn; similar soil and situation. Has a variety of short stems not over 12 inches in length, with thick tufts of lance-shaped leaves, three stems of 11 inches circumference, three smaller stems 8 inches to 9 inches, and two young growths, one with complete stem and head, the other a vigorous leafy shoot springing from same root as the last named. Age of plant quite unknown. It looks crowded, and the younger growths have hardly room to develop. Can old stem be cut out without injury, and what season best for the operation? There is a stump of an old stem which must at some time have died or been cut down. There is no definite shelter around the plant or Grass. Would such

be beneficial in winter in a rather windy position?—CORSWOLD.

[From your description, the *Yucca* would appear to be *Y. gloriosa*. Probably the plants has been broken down with snow in winter. The leaves being very stiff, the snow gathers in the crowns and eventually breaks the plants down. Plants with a two or three-lobed head often suffer to such an extent that the removal of the large head-crowns is a necessity. Old plants of this character require support. If any such accident has occurred to your plants this would account for the loss of the breaks or growth and their being crowded about. Any of the old stems may be cut away with a saw at any time now with impunity, plastering the cut with soft-tamped clay. Any crowded shoots may be pulled off the main stem, and secured with a heel attached may be rooted by planting firmly in a pot. The plant is quite hardy, and in your district would not require protection. Indeed, it rarely suffers from any cause except that stated above, but this is disastrous where old groups are affected.]

Alonsoa Warscewiczii.—This Central American half-hardy annual has been very beautiful lately, the plants being literally clothed with the small pretty crimson blossoms, which, combined with the graceful habit of growth, place it in the first rank among plants that are raised annually for garden embellishment. I sowed the seed in pans in gentle heat

during March and prick the seedlings off into boxes when large enough. In due course they are hardened and eventually planted out at the latter end of May in groups of from nine to twelve plants, allowing a distance of a foot between each. Grown in this way they form good sized clumps and so partly support each other, a few sticks round the outside being all that is needed in this direction.—A. W.

Double white Narcissus falling.—I have a bed of double white Narcissus, generally a very beautiful bed, but the leaves are so long in dying, and there are so many bulbs in the bed, I can plant nothing for autumn, and the bed is unsightly. I thought of taking a few of the Narcissus out and planting a few *Gladiolus Brechtianus* in the bed surrounded by Box. Would they do mixed up with the Narcissus? I have three small plants of *Everlasting White Pea*. The bed is rather shaded and is rather a dry garden, but I think a patch of bright white would be nice, especially as there is a background of clipped Yew.—KITTA.

[In a year like this, characterised by general dullness and a shortness of sunlight, the double white Narcissus is always slow in going to rest. Indeed, we have known it to retain perfectly fresh foliage even after July, the foliage receiving continued support by the ever-renewing roots at the base. At this time of year the bulbs will have emitted a large number of new root-fibres, and to now interfere and replant would certainly not improve the flowering of those moved. As it is not possible to deal with the *Gladiolus* at this time, we think your better plan will be to wait until the flowering of the Narcissus is over next spring, when you may

deal with the bed at once. As the bed is so full, why not make a second bed, and in doing so make arrangements accordingly? If you can arrange a second bed, it would be a good plan to plant the Narcissus quite 8 inches deep, which is sufficient to allow another crop being planted on the surface. Tuberous Begonias form a capital crop for summer display, and are bright withal, easily wintered in boxes of sand, and may be started in boxes in April and planted in mid-June. Another plan, and likely to give good permanent results, would be to plant rather thinly bulbs of *Lilium tigrinum* Fortunei in conjunction with the Narcissus. In such case there would be no need to plant deeper than 6 inches, and the Lilies would give better permanent results than the scarlet Gladioli. If, however, you only wished for a few of the Gladioli, it would be quite easy to plant the roots of these in February with the help of a small handfork. If planted 3 inches deep this would suffice. For a good, effective, permanent bed, however, we can recommend the Lilies and Narcissus.]

CHRYSANTHEMUMS,

SEASONABLE NOTES.

We have now entered on a critical period of the plants' growth, and housing will in most cases be in full swing, provided, of course, that the buds are well set. On no account put a plant under cover unless the buds can be discerned. Where the plants had plenty of room in their summer quarters the wood has ripened pretty well, and, all things considered, the bloom prospects should be about the average. I speak from a decorative point of view. Where several hundreds of plants are grown, the housing sometimes takes considerable time, all the pots requiring to be washed before taking them inside. In view of this, I think a capital plan to adopt is to start cleaning the pots a few days previously, arranging them afterwards in a sunny position, facing south if possible. This has the double advantage of the plants being handy for lifting in, and it also gives them a more suitable position for covering them at night with canvas or tiffany as protection from slight frosts. This covering, of course, will only be required where the plants have not set their buds. I find some varieties will be nearly three weeks later in setting than was formerly the case, and this, no doubt, will have its advantages from a market gardener's point of view. Mildew seems to be prevalent, and an effort should be made to remove every trace before taking the plants inside, otherwise the whole collection may be disfigured. Liquid-manure may now be given with safety, as all the virtues in the soil will be spent ere this, and something must be given every eight or ten days to keep the roots active. In giving stimulants of any kind it is always safer to err on the weak side. Be sure and have a tub handy, filled with rain water, having a bag of soil suspended in it. This is an indispensable invigorator to the plant in many ways.

Bridge of Weir, N.B.

D. McIVER.

CRIMSON EARLY-FLOWERING VARIETIES.

A few years ago early-flowering crimson Chrysanthemums did not exist—at least in that section confined to the Japanese flowers. Harvest Home, introduced about 1895 or 1896, was the first in this colour. Previous to this period there was a goodly number of orange-coloured flowers, and others, too, possessing warm shades of colour. Harvest Home is of a bright and rich shade of crimson, tipped golden-yellow, and comes into flower at any time after mid-September, and, when propagated early and grown on freely, even earlier. These plants, like other early-flowering kinds, will continue to blossom until really severe weather comes. The height of the plant varies from 2½ feet to 3½ feet, and the habit is good. In so far as its free-flowering characteristics go, it may be regarded with favour. Ryeeroff Crimson, introduced in 1901, was looked upon as another acquisition. Its colour is a shade of deep chestnut-crimson, and the plant, which has a good habit and attains to a height of about 3 feet, flowers freely. Unfortunately the

flowers are very thin, and, unless the plant be grown strongly or freely disbudded, the blooms leave much to be desired. In Goacher's Crimson we have a superb variety, and one which all interested in the early-flowering Chrysanthemums should grow. The flowers of this variety are much larger than those of most of the early-flowering Japanese kinds, and each one is developed on a long, stout, erect footstalk, without the need of disbudding. The colour is a deep rich crimson, and the long florets, which are of medium width, have a beautiful golden-bronze reverse. Under artificial light these flowers are very rich and effective. The plant attains to a height of about 3 feet, and is a recognised September-blossoming kind. A curious discovery made this season is that of a new variety of continental origin, and distributed under the name of Mons. J. B. Chauvin. The blooms of this variety are as nearly alike to those of Goacher's Crimson as possible, and I very much doubt whether, if the blooms were arranged in vases, side by side, it would be possible to distinguish them. Careful comparison has been made between them, and the only distinction, so far as I could trace, was a slight difference in the leafage, and possibly a week's difference in the time of coming into flower. This latter, however, is hardly worth considering. Whatever may be thought of these two sorts because of their similarity, they are undoubted acquisitions. A few days ago I saw a seedling named Mrs. W. Sydenham, of a charming, free-flowering, deep, rich crimson. The plant gave promise of making a good border sort, as its blossoms were of a reflexed Japanese kind, which throw off the rain, and last well in wet weather. The colour in this instance was very rich, and the plant, besides being a profuse bloomer, also possesses a nice branching and sturdy habit. There are two or three late October-flowering kinds which should not be regarded as typical early sorts, as their period of blooming is much too late in this climate. The sorts referred to are Ruby King, syn. Crimson Queen, M. E. L. Usmyer, Alle. Sabatier, Mme. Max Dufosse, and others of kindred shades of colour. E. G.

Chrysanthemums—early-flowering kinds.—Never have these plants been seen in better condition than during the past month, and there is the promise of a grand display for some time to come. In August several of the best sorts began to bloom. At that time Mmc. Marie Masse and its sports were in flower. Mauve-pink blossoms were represented by the parent plant just alluded to, cerise-pink, tipped gold blossoms, by Rabbio Burns, creamy-white flowers by Ralph Curtis, crimson and bronze blossoms by Crimsoa Marie Masse, and rich yellow by Horace Martin. The above may be regarded as ideal for border culture, possessing as they do a sturdy, branching style of growth, and very free-flowering. Other excellent sorts are Francois Vuilhermet, lilac-pink, free and branching; Mme. Casimir Perrier, pink and white, wonderfully profuse, and with a capital habit; Harvest Home, still one of the best crimson kinds; Lemon Queen, a mass of deep yellow blossoms of good form; Henri Yvon, yellow, tinted rose, large and full blooms, and very continuous in its flowering; and Harold Olivier, a pretty soft pink sort and quite new. —E. G.

TREES AND SHRUBS.

Good hardy Azaleas.—Could you recommend about 12 modern sorts of Azaleas, mentioning colours? I have a garden where they grow well, and I have a good variety, but I wish to plant a few more of the most recent sorts, not indica. —R. S. HANMOR.

[In the production of most of the newer hardy Azaleas, the Chinese *A. mollis* has played a part, the effect of this species being seen in the larger flowers and more compact habit of many of them. A few of the best are: Alphonse Lavallée, bright orange; Anthony Koster, bright yellow, perhaps the finest hardy Azalea we have; Charles Darwin, bright red; Comte de Gomer, bright pink; Dr. Pasteur, orange-red; Frère Orban, creamy white; Hugo Koster, salmon-red; J. J. de Vink, soft rose; Mme. Anthony Koster, orange-pink; M. Desbois, rosy-scarlet; Peter Koster, orange; and W. E. Gumbleton, golden-yellow.]

GARDEN WORK.

Conservatory.—This is the time of the Chrysanthemum under glass, and well-grown plants thickly placed are certainly very effective. For decoration one does not want many varieties, and many of those grown for exhibition are not suitable for indoor decoration. White, yellow, red, or crimson, bronze, and pink-flowered kinds, arranged in groups of one colour, are the most attractive, with plenty of Ferns and fine foliaged plants to tone down the brightness. Really well grown, bushy specimens look well isolated among fine-leaved plants, and in a large house there is scope for variety of treatment. Scarlet *Salvia* will now be coming into bloom, and are very bright, and in a well ventilated house the flowers will last for some time. After taking Chrysanthemums to the conservatory the vaporiser should be used to clear off any insects which may be upon the foliage or buds. There is not likely to be many at first, but they increase rapidly, and they spoil the flowers when they have increased and multiplied among the petals, which they will do rapidly if the precaution has not been taken to clear them out before the flowers expand. Last year I was troubled with the rust on the foliage, this year the plants are perfectly clean, and, so far as I have seen, there is less rust about generally. When grown into large bushes the Eupatoriums, especially *E. odontium*, are beautiful plants for winter blooming in a large house. They are very easily managed. I have had plants three or four years old, which have been cut back annually after flowering and planted out in May, that when lifted in September were perfect specimens 4 feet to 5 feet in diameter, and later on were covered with their white, somewhat fluffy panicles of blossoms. It is, perhaps, not just the flower a lady would select for cutting, but when a large house has to be filled and the Chrysanthemums are getting shabby this comes in well with the *Salvias* and forest things. Very charming just now are groups of Begonias, the most useful being *Gloire de Lorraine*. Place them thinly among Ferns. The different varieties of *Pteris* are the best for this work, because they are lasting in a low temperature, and until the Chrysanthemums are over the fires must be kept down, though enough heat must be given to dissipate damp, which soon spoils the flowers.

Stove.—For the present the night temperature will range between 60 degs. and 65 degs., or a little lower if there should be a sudden fall in the outside temperature. We do not want to push things to extremes at present, and pretty well all stove plants will do in the temperature named. Very little ventilation is required when November comes in till the days lengthen again after Christmas. Even the best constructed houses are not air tight, and it is not desirable that they should be, as the fresh air filtering through the laps of the glass keeps the internal atmosphere pure without unduly lowering the temperature. Of course, on a bright day, if the thermometer runs up to 80 degs. a little ventilation can be given along the ridge, but tropical plants do not want sudden changes. Keep *Draenas* and other coloured-leaved plants near the glass. Palms and Ferns will be better where the light falls upon them in a subdued degree, under creepers or otherwise. Of course, no shading will be required now, and the water supply, both at the roots of the plants and in the atmosphere, must be regulated according to temperature. On a bright sunny day plants will dry rapidly and will require to be watered with care. Among the small things of pretty growth which are useful are *Centradenia rosea*, *Rivina humilis*, *Ficus radicans variegata* (pretty basket plant), *Cyperus alternifolius variegatus* (pretty table plant), Sultan's Balsam (*Impatiens Sultanii*), *Pentas carnea*, *P. rosea* and *alba*, and *Streptocarpus* in variety. The last-named is a tower of strength in good hands, as very large plants may be had if enough pot room is given.

Orchard house.—If the trees are grown in pots they will now be outside, and by this time all those trees which require larger pots should have been shifted on, and others which it is not intended to repot this season should have had as much of the old soil as possible

picked out from the surface and the pots filled up again with good turfy loam fortified with bone-meal and manure, and the whole rammed in firmly. The trees should then be placed on boards, or something that will keep out worms, and before frost sets in the pots should be sheltered with long litter or Bracken to keep the roots comfortable. At the present time the orchard house has probably been turned into a plant house. The common course is to fill the house with Chrysanthemums. I know more than one successful grower who always grows his prize blooms in the orchard house, the Peach-trees being taken out as soon as the fruits are gathered, and kept out till the beginning of January. Of course, during the autumn, when the weather is damp enough, fire must be used to keep the atmosphere reasonably dry, and on fine days the ventilation is free. Heaps of new unslaked lime are found useful in Chrysanthemum houses for drying the atmosphere and keep down the cost for fuel, and the slaked lime can be used for the land, and a fresh supply brought in.

Mushroom-house.—There is still plenty of Mushrooms outside when the beds are protected and carefully managed; but there is never any glut of Mushrooms in winter, and the inside beds should be encouraged, and more beds made up as the manure accumulates. Be careful in selecting the manure, and obtain it only from stables where the horses have hard food and are in good health. The manure from a horse or horses which are under a course of medicine and bran mash may at any time destroy the prospect of a crop, therefore the source of the manure supply must be carefully considered. It is rather too soon yet to begin forcing Sea-kale, but as soon as the crowns are ripe the roots may be lifted and kept ready to be introduced from time to time. Rhubarb also may soon be started. As the Apple crop is a light one, there will be a demand for Rhubarb by-and-by.

Window gardening.—Hyacinths may now be placed in glasses, and stood in a dark cupboard for a month or so to make roots. The single-flowered varieties are best for the purpose. Replace the water as it evaporates, so as to keep it near the base of the bulbs. The Chinese Sacred Lily may be started in bowls, surrounded by a little soil kept in place by pebbles. Crocuses, Snowdrops, early Tulips, and Narcissi should be potted for the room and plunged in ashes or fibre outside for six weeks.

Outdoor garden.—Cuttings of Calceolarias will strike freely now in loamy soil, with a sprinkling of sand on the top, in any close cold-frame. Do not crowd the cuttings. To have sturdy plants they should not be closer than 3 inches. This will be room enough for the winter, and in February, or early in March, transplant to other frames where protection can be given, and plant out finally towards the end of April, so that the plants may get established before the hot weather comes. Calceolarias have lost caste of late years, chiefly through their not being reliable, but as no other plant that gives just the soft shade of yellow of the Calceolaria—especially *C. amplexicaulis*—it cannot quite be done without. The taste for ribbon borders and large masses of bright colours has, to a large extent, died out, and therefore Calceolarias are not required in large numbers, though a few are necessary, and the late struck cuttings, taken when the shoots are soft, make the best plants. Cuttings of Euonymus, Ives, and Aucubas, will strike now in cold-frames kept close in a shady spot. All Gladioli should be lifted, dried, and stored in a cool but frost-proof room, as soon as the growth is ripe. Dahlias also, when cut by frost, and Salvia patens, should be lifted and the roots pecked in sand. No one has too much of the Salvia, and every root should be taken care of and started in spring, and the ends of the young shoots rooted as cuttings. Seeds may also be sowed and sown in heat in spring. Among the cheapest plants for creating masses in the borders are Wallflowers and Forget-me-nots.

Fruit garden.—The time for planting fruit-trees is drawing near, and intending planters will ere this have selected and prepared the sites, or at any rate, the work will be in progress, and I need hardly say that the

preparation should be thorough. For planting on a large scale the steam cultivator to tear up the land will do good work, and the land should be gone over at least twice in opposite directions, so as to completely break it up. Any further preparation can be done by horse labour. The spade does good work, but it is very expensive, and to plant land with fruit-trees to make a profit we must keep down the initial cost. Planters of Apples should depend chiefly upon good market sorts, and my selection for half-a-dozen will be: Bismarck, Newton Wonder, Lane's Prince Albert, Bramley's Seedling, Cox's Orange Pippin, and Baroack's Beauty. If early sorts are wanted, we should fall back upon those of the Codlin family, of which Lord Suffield, Lord Grosvenor, Mank's Codlin, and Ecklinville Seedling are types. Plant early and plant well. Probably a mixture of dwarf trees on Paradise and standards on the Crab will give the best results. The standards should be about 24 feet apart, and the dwarfs filled in between 10 feet and 12 feet apart. By the time the dwarfs are failing the standards will have occupied the ground and may be left ten or fifteen years longer. The life of a tree depends in some measure upon the character of the soil, and the treatment given, especially in the matter of top-dressing.

Vegetable garden.—This has been a good season for late Peas, especially for such kinds as Ne Plus Ultra and the old tall Marrows of the British Queen types, which have made a second growth. Late Cauliflowers also have been, and will be for some time, good, if the weather continues mild. In this matter of Peas, Cauliflowers, and French Beans we are very much at the mercy of the weather. One night's sharp frost may destroy everything tender unless protected, but it is difficult to apply protection, except on a small scale. Cauliflowers can have the leaves broken down or tied over the hearts, or the plants may be lifted with balls and set in a deep cold pit, or be planted in trenches where shelter can easily be given. The earthing up of Celery should be finished as soon as possible, as there is not much growth after October. Transplant autumn-sown Onions; sometimes Shallots are planted in autumn for early use. They succeed well in well drained soils, but in damp, heavy soils leave the planting till March. Brown Cos Lettuces set out now upon drained borders will be about right for standing the winter, and the plants need not be large. If slugs or snails are likely to be troublesome, scatter some sifted ashes among the plants. Finish taking up and storing all roots likely to be injured by frost. Clear away all exhausted crops of Tomatoes. The outside crops have not been satisfactory everywhere, but I know several dry, sunny spots where the crop has paid well. There has been but little disease and the price has been higher than last year.

E. HOBDAV.

THE COMING WEEK'S WORK.

Extracts from a Garden Diary.

October 27th.—Shifted on a further batch of Cinerarias and Primulas. Potted off herbaceous Calceolarias from boxes. Planted more bulbs in beds and borders, chiefly in masses of one colour. Planted a lot of Crocuses, Narcissi, and Snowdrops under trees on lawn. Mowed lawns for last time. Cleaned and put away mowing machines for winter. The roller and the broom will keep lawns and walks in condition now. Commenced making additions to rock-garden with a view to classify various plants.

October 28th.—Finished all the root-pruning of fruit-trees we intend doing this season. The Apples we intend planting shortly are Newton Wonder, Bismarck, Baroack's Beauty, Lane's Prince Albert, Worcester Pearmain, Cox's Orange Pippin, and Fearo's Pippin. Finished planting cuttings of Roses of various hardy kinds. The cuttings were taken off, prepared, and laid in last month, waiting for an opportunity to plant. Most of the Apples and Pears, except a few very late sorts, have been gathered. Strawberries in pots have all been looked over to remove runners, and the pots plunged in ashes.

October 29th.—This is the season when an effort should be made to get rid of insects

under glass, and having got the occupants of the plant-houses arranged, we are going through them with the vaporiser, so that we may begin the season of shortening days clean. Now-a-days there is a good deal of moving plants about from different houses to conservatory, and unless all are clean to begin with things soon get mixed, and then waste creeps in. Pruned Vines in early house. Selected a few of the best ripened cuttings for propagating, and laid them in till January.

October 30th.—We are still busy making preparations for a good outdoor show in spring. Several beds badly infested with the snake millipede have been excavated 2 feet deep, the soil carted away, and the beds filled with loam from an old pasture and some old manure. The reason for this was it was impossible to grow bulbs in the beds. Tulips, Hyacinths, Lilies, and other bulbs were killed time after time, though gas-lime and other things were tried and found useless. Now we hope we shall succeed.

October 31st.—Made up a hot-bed for forcing Asparagus. The plants were cut down some time ago to prepare the roots for lifting. Tuberos Begonias taken from the beds have been stored close together in the border in the orchard-house. We find they keep well in this place. We have kept them well under the stage in a cool plant-house; in fact, all the plants which have flowered in the conservatory will be stored in pots in that position, with the pots laid on the side if there is much drip from the stage. We have a piece of land marked out for trenching, where men can go to fill in spare time.

November 1st.—Some attention has had to be given to the drain which keeps the stoke-holes dry. The outfall in process of time and other causes had become blocked, and all important drains require looking to from time to time, especially where trees are growing near and the roots penetrate the drains. For draining stokeholes we have found it necessary to use glazed pipes, and see that the joints are secured properly with cement. All our full-grown Lettuces remaining outside have been covered lightly with dry leaves, with a thin covering of Bracken on top to keep the leaves in position.

BIRDS.

Death of Canary (J. W. F.).—This very old bird appears to have died from atrophy, a progressive wasting of the body, for which there is no cure unless the treatment be undertaken at its very commencement, although, as a rule, it does not cause speedy death, for a bird so affected may live for months. In this case the digestive organs being worn out from age, the food failed to nourish the system properly, hence the ravenous and constant pecking of seed. You appear to have fed it judiciously, and to have given it every attention, but its age was against it. The only fault in the feeding was the rather large proportion of Hemp-seed, which should always be given with a very sparing hand to Canaries.—S. S. G.

(Antique).—Inflammation of the lungs appears to have been the immediate cause of death in this case, due, in all probability, to a chill. Much care is necessary in spring and autumn to protect Canaries from sudden changes of temperature and cold currents of air. Lung trouble is one of the most frequent complaints to which cage-birds are subjected, owing, in great measure, to our changeable climate. The only remedy to be depended upon in cases of this kind is to keep the patient in a high temperature, which should be regularly and constantly maintained night and day.—S. S. G.

The Prize Winners this week are: 1. Mrs. Deane, Fairfields, Fareham, Hants, for Corner in Fairfields Garden; 2. Miss Sophie M. Wallace, Ardnamore, Lough Eske, Donegal, for Lilium giganteum.

Request to readers of "Gardening."—Readers, both amateur and in the trade, will kindly remember that we are always very glad to see interesting specimens of plants or flowers to illustrate, if they will kindly send them to our office in as good a state as possible.

CORRESPONDENCE.

Questions.—Queries and answers are inserted in GARDENING free of charge if correspondents follow these rules: All communications should be clearly and concisely written on one side of the paper only, and addressed to the EDITOR of GARDENING, 17, Farnham-street, Holborn, London, E.C. Letters on business should be sent to the PUBLISHERS. The name and address of the sender are required in addition to any designation he may desire to be used in the paper. When more than one query is sent, each should be on a separate piece of paper, and not more than three queries should be sent at a time. Correspondents should bear in mind that, as GARDENING has to be sent to press some time in advance of date, queries cannot always be replied to in the issue immediately following the receipt of their communication. We do not reply to queries by post.

Naming fruit.—Readers who desire our help in naming fruit should bear in mind that several specimens in different stages of colour and size of the same kind greatly assist in its determination. We have received from several correspondents single specimens of fruits for naming, these in many cases being unripe and, in other cases, so ripening that it is necessary that the specimens of each kind should be sent. We can undertake to name only four varieties at a time, and these only when the above directions are observed.

PLANTS AND FLOWERS.

A yellow Clematis (J. Cully).—The Clematis to which you refer is no doubt C. graveolens, which in England grows to a height of 20 feet, planted at the foot of some old Holly-trees. In colour it is very good in this autumn and until very late, flowers and seeds being very beautiful.

Niphetos in cool greenhouse (Mrs. E. Brown). Very little pruning is required for this Rose, if you desire it to grow into a large plant. If the shoots are crowded one or two may be removed from the centre, and the growths left produced, if well ripened, pruned back to a stem pump eye. This would be best done early in the new year. If at any time the plant is growing too tall for its position, then you may cut back severely when the growths are at rest. It will not be necessary to top each year, a top-dressing being quite sufficient. A handful of bone-meal mixed with the compost used for top-dressing will be of much advantage.

Tennis lawn (A. Bon).—The reason why the Grass did not grow on the portion of your tennis lawn, which you levelled up with clay, was that then the clay was very poor and incapable of sustaining plant life. Very likely the surface is now sweeter, and it is not improbable you may now sow down on it. But you may do great good all the same if you will fork off some 3 inches of the clay surface, remove it, and replace it with screened soil from the kitchen garden. If so much soil cannot be found, mix the clay with a good dressing of lime and wood-ashes, then you will stir the clay surface 2 inches or 3 inches deep, then when a good dressing of lime and wood-ashes, then the soil has been well pulverised by frost, rake it well over, level it, then get proper lawn Grass seed and sow it, doing it in April. If well rolled on a dry day growth soon follows, and shortly a good lawn is formed.

Treatment of Gloxinias (Henry Holberry).—As the leaves commence to turn yellow previous to dying down do not stand them under the stage, as is so often done, but give them all this light and air possible at that period. During the winter they may be either allowed to remain in the pots they have grown in, or turned out, shaken clear of soil, and laid in a box of dry sand or soil. The structure they are kept in during the winter should not fall below 45 degs. at any time. Do not place too near the hot water pipes, and if the soil gets very dry it should be watered. At the end of February or early part of March the tubers must be potted, but be careful not to overwater before they start into growth. The best soil is overwater to grow them in is a light loam, mixed with leaf-mould, rotten manure, and sand. They can also be propagated from leaves, but the best way is to raise from seed in the spring.

Renovating old garden (Amateur).—We cannot accept your offer of a prize, and there is no need for it in your case. What you propose to do, getting the ground trenched, and in the process casting out all refuse that will not be productive, is the only proper way to deal with the ground. If you dress it well with crushed unslaked lime as the trenching proceeds so much the better. Get the trenching done at once, and in doing so keep the present top soil to the surface, well breaking up the subsoil in the spring, before cropping, add a dressing of half-decayed stable manure, and then if the tubers be kept freely used amongst the crops, you should have good ones of anything grown. As your stone wall is on the south end of the garden, its inner face looks north. On that face you could plant Morello Cherries, Red Currants, and Gooseberries, keeping them trained and nailed; or, if preferred, you can plant climbing Roses.

Raising Briers from seed (B.).—The pods must not be allowed to get dry. Stick the stalk end into some damp sand placed in pots, and stand on a shelf in the greenhouse or pit free from frost. Then in January prepare some 5-inch pots by half filling them with small bricks, then fill up with sandy soil, consisting of sifted sand and manure. Press this firmly and sow seeds about 1/2 inch deep and as much apart. Plunge the pots in ashes up to their rims in a cold frame, protecting them from severe weather. Usually the seedlings appear in eight or ten weeks. As soon as they show their third leaf prick out into small pots and return to the pit, keeping them near the glass. Do not water them much or they will damp off. Care must be taken to afford plenty of air on all favourable occasions. About June you may plant out the little seedlings from their pots, but they will need watching or birds will soon destroy all your labours. When in the frame be on the look-out for woodlice, as they are very partial to little Rose plants, and worms, too, will often draw them under the soil.

Chrysanthemum classification of varieties (C. S. P.).—Your list embraces several types of this autumn flower and is not limited to Japanese and in-

curved sorts, as you suggest. The only incurved varieties in your selection are Major Bonifon and Baron Hirsch. The first-mentioned is a rather late variety, and the latter a late October-flowering kind. Japanese varieties are represented by the following: Thomas Wilkins, W. H. Lincoln, Mme. Carnot, Phœbus, Lady Hanham, Swanley Giant, Queen of the Exe, and Mrs. F. A. Bevan. Crimson Pride, Mme. C. Desgranges (not White Desgrange), O. J. Quintus, White Quintus, Yellow Lady Selborne (not Yellow Lady Matheson), Ryecroft Scarlet, Etoile de Feu, Queen of the Earlies, Lady Selborne, Source d'Or, and Ivory are free-flowering semi-early and midseason kinds. All except the last-mentioned variety should flower in late October and early November, and should not be severely disbudded. Jules Fourm was a new variety, Miss Mary Anderson is a small-flowered single sort, and is one of the prettiest and best of this section. Early November is its period of flowering.

TREES AND SHRUBS.

Treatment of Hydrangeas (O'Donnell A. Boo).—We presume that the Hydrangeas referred to by you are the variety of H. Hortensia, known as Thomas Hogg, while, on the other hand, they may be the deciduous H. paniculata grandiflora. If they are Thomas Hogg you did not do wrong to cut them down to within three eyes of the base as soon as their flowers were over; but if H. paniculata grandiflora, the pruning should not be done till the leaves have fallen.

Split bark on trees (Fairford).—It is most probable that the Plum, Apple, and Paulownia trees on your lawn have felt the effects of the unusual moisture which has fallen during the summer. Previous dry seasons had doubtless caused the bark to harden unduly and become set, so that when the greater rainfall of the present season caused the formation of a greater thickness of inner bark, or what is known as the cambium layer, which ultimately becomes hard wood, thus locking the bark to split open to give room for this inner layer to develop. We see no reason whatever for alarm in relation to your trees. Probably the splitting is far less on either than is commonly seen on the Birch, for instance, and the cambium layer will soon fill the interstices. If you tear the cracks apart with a sharp knife, give the stems a good thick coat of lime-soap and coating, with some soft soap, made as a paste and painted over the bark.

FRUIT.

Increasing the Logan Berry (Sherwood).—This is easily increased by division of the roots, and if this is done now, and the pieces grown on in small pots and planted out in March, the plants will stand a good chance of doing well.

Gathering Pears (B.).—It does not answer to pick Pears unripe, for they shrivel and are not worth much. On the other hand, it is not well to allow the late Pears to hang too long. Pimston Duchesse is not a late Pear, and should be gathered as soon as the pips begin to get brown. Maréchal de la Cour is also an October Pear. Late varieties, such as Josephine de Malines and Knight's Moorarch, should be gathered about the end of September; there is nothing gained by letting them hang later.

Pruning an Almond-tree (B.).—Nothing was more natural than that your recently planted Almond-tree should not shoot, and should cease to grow, especially if you want to get a dense head shorter back the present season's shoots to fully one-half their length so break the leaves fall. That will cause the branches to break freely in the spring. The Almond naturally produces a spreading head, and even if your tree were untouched the branches would in time become spreading. But you will help to that end all the sooner if you will presently prune the tree as advised.

VEGETABLES.

Gas-lime (Anxious).—To ground that is now free of crops, and which you propose to dress, gas-lime should be applied once at the rate of 2 bushels to 3 rods of ground. Put down in heaps of bushel, and the spread evenly over the surface. The lumps, if large, should be well broken up. Exposure to the weather will help to pulverise it. After you have thus exposed it for a month you may dig it in. Cropping must not take place till February or March, when, if you think it necessary, you may apply manure before preparing it for sowing or planting, as the case may be.

SHORT REPLIES.

W. K.—Kindly make your query plainer, giving size of garden, district from which you write, etc.—B.—Prune your Privet hedge towards the end of October.—N. O'Shea.—Yes. Lift and replant the tree, adding fresh soil with very little manure in it.—Inquirer.—I do not suppose you mean Statice latifolia, with wide-spreading flower-stems, bearing a profusion of small purplish-blue flowers. 2. Cut it away at once. 3. Freshly-slaked lime would be far better than the gas-lime in such a soil as you have.—Richard Thurnham.—Write to any of the wholesale seedsmen.—H. Hayward.—The only thing you can do is to trap them or shoot them.—Snowdrop.—1. See article in a coming issue re Peaches. 2. Morello's cooking Cherry, is the only Cherry that will succeed on a north wall.—P. C. F. L.—"Soils and Manures" by J. H. Cassell and Cassell and Co. Norfolk. See flower seeds are used for poultry. We have never heard of their being given to pigs.—Scelus.—If the weed destroyer had been properly applied, you should have had no more trouble with the weeds.—Mrs. Mynor.—You will find an illustration of Begonia Turnford Hall, a form of R. Gloire de Lorraine, in our issue of Nov. 23, 1901, p. 505, with full instructions as to culture. This can be had of the publisher, price 1/3d.—N. P. D.—See reply to "Not-seller" in our issue of Sept. 6, 1902, p. 350.—Postman.—1. Do not understand your query. 2. Yes, using Hyacinths, Tulips, Daffodils, Crocuses, etc. 3. Try Wallflowers and Forget-me-not mixed with the bulbs.—M. H.—You can use any of the artificial manures, which can be had from any horticultural firm. Horse manure would answer the same purpose if you can get it.—T. T.—"The Book of the Apple" is published by Mr. John Lamm, The Bodley Head, London. We think the price is 2s. 6d.—D. Kerr.—A malformation, a lacinated stem and of a blue color.—G. P.—Kindly send the fronds here for a time, and we will do our best to name them for you.

—E. P. Goddy.—We have never published any such articles as you refer to.—M. J. K.—Worms are injurious to pot plants in that they always stop the drainage. Water with lime-water to bring them to the surface, when they may be destroyed.—Mudge.—1. You must not mutilate the bulbs in any way; plant as they are. 2. Only cut off any of the broken pieces of roots, and take care to beve the hole big enough, so that you can well spread out those that are left.—M. L.—If you want dwarf plants you may grow Alyssum, Arabis, Androsace, Aubrietia, Campanula, Dianthus, Iberis, Phlox subulata in variety, Sedums, Saxifraga, Thymes, Veronica, and many others of a like nature.—Amateur Gardener.—It is quite impossible to say, to many things such as distance, nearness to town, and demand for such produce as you mention, having to be considered. Besides which, without practical experience in market work and owing to the severe competition now-a-days, such an undertaking is, to say the least, very risky. Even a man with knowledge of such work often fails.—Francis Edwards.—We have no knowledge of the book to which you refer.—George H. Smith.—It is quite impossible to advise you what to do without seeing the ground. Your best plan will be to consult a gardener in the neighbourhood.—Charles Williamson.—The shoot of Nasturtium which you send is what is known as "isolated," this frequently occurring in various forms of Lillium, most particularly L. auratum.—J. H. B.—You will find a list and description of Early Chrysanthemums in our issue of Oct. 18, p. 438.—A. A. C.—See reply to Mrs. Walton re Sox-edging, in our issue of Oct. 11, p. 425. You can cut the Yew down in the spring, and the Laurustinus immediately after flowering.—C. S. M. Coulthard.—Apply to Messrs. Barr and Son, King-street, Covent-garden. You will find an exhaustive article and illustrations dealing with Fritillaries in our issue of Nov. 23, 1901, p. 507, which can be had of the publisher, post free, 1/3d.—S. W.—You cannot do better than use foot-water. Hang a bag of soot in a barrel of water, and use the water when clear.—Bobus.—Seems to be a very good Apple in the way of Xcello's Goddy, but with which we hope to compare.—G. M. Sandars.—If you had given us any idea as to where the plant was growing it would have been far easier to have verified the specimen which you sent. Kindly send again, and we will examine it.

NAMES OF PLANTS AND FRUITS.

* Any communications respecting plants or fruits sent to name should always accompany the parcel, which should be addressed to the EDITOR of GARDENING ILLUSTRATED, 17, Farnham-street, Holborn, London, E.C. A number should also be firmly affixed to each specimen of flowers or fruit sent for naming. No more than four kinds of fruits or flowers for naming should be sent at one time.

Names of plants.—W. B. R.—Aster Amelius benedictinus; 2. A. P., Acer Negundo variegatum; 3. Sedum in flower; 3. Berberis Aquifolium; 4. Berberis Darwinii; 5. Mrs. Tucker.—We cannot undertake to name florists' flowers.—W. H. Brown.—1. Aster levis; 2. Aster Nova-Engliæ var.; 3. Specimen insufficient; 4. Poor form of Aster acris.—L. C. M.—The deciduous Cypress (Taxodium distichum).—B. P. R.—The Great Japan Kooiweed (Polygonum cuspidatum). See last week's issue.—Croydon.—1. Seems to be a drawn-up specimen of the Golden Saxifrage; kindly send flowers; 2. A hybrid Dianthus; cannot name without flowers. The leaves have been attacked by the Marguerite Daisy-fly, several of which we found in the leaves.—R. Greening.—Cockspur Thorn (Crataegus Crug-galli).—H. Lucas.—Crataegus Crug-galli pyracanthifolia;—Ally Sloper.—1. Aster Nova-Engliæ ruber; 2. A. Novi-Belgii var.; 3. A. ericoides; 4. A. diffusus horizontalis; 5. A. cordifolius var.; 6. Prænarum uliginosum.—S. Scales.—Begonia metallicæ; 2. Ophiopogon Jaburac variegatum; 3. Impatiens Sultanii; 4. Sedum carotum variegatum; 5. Sempervivum Haworthii; 6. Sedum in flower; 7. The Mexican Orange-flower (Choisyia tenax); 8. Oxalis corniculata rubra.—Frank Piper.—1. Loasa hispida; 2. Chrysanthemum maximum; 3. Acer Negundo variegatum; 4. Virginian Sunnach (Rhus typhina).—M. J. Fooker.—1. Yellow, Rudbeckia Nswmannii; 2. Pyrethrum uliginosum.—Ireland.—4. Adiantum cucucatum; 8. Rudbeckia Nswmannii; 12. Aster Amelius; 16. Stachys lanata. L. Lawrence.—Red leaf, probably The Poison Ivy (Rhus toxicodendron), sent out by many people as Ampelopsis Hoggii; the other about is the Cockspur Thorn (Crataegus Crug-galli).—Edward T. O'Connell.—Scales also Pyrethrum. Saw the seed in the open early in April, and this nut as may be necessary.—W. R. Price.—We cannot undertake to name florists' flowers.—Keatinge.—Veronica rupestris.—J. D. D. M.—Specimen insufficient.—H. S.—We should say the illustration represents Pyrethrum uliginosum.

Names of fruit.—N. Bonne.—Calville Rouge.—Hulton, Clacton.—1. Nelson Cudlin; 3. Cellini Pippin; 4. Durondeau.—J. Stroud, Berke.—Pears: 1. Beurré Superfin; 2. Beurré Diel; 3. Maréchal de la Cour; Apple: 2. Not recognised, probably a local variety.—John Tibbena.—1. Lane's Prince Albert; 2. Margil; 3. Kerry Pippin.—Blotman.—Apple, Worcester Pearmain; Pear, Beurré Clairgeau.—W. R. Woodrow.—All the numbers had become detached. Large green, Lord Suffield; smaller green, Keewick Cudlin; Pearmain-shaped, Reineke Green; brown and green, not recognised.—G. C. G.—Blenheim Orange; 2. Emperor Alexander; 3. Small's Admirable; 4. Cox's Pomona.—Miss Penfold.—Kindly send better specimen and also fruit.—A. W.—Apple, Winter Hawthornden; Pears: 1. Not recognised; 2. Winter Nelia.—D. Masters.—Pear Marie Louise d'Orléans.—Mardon's Hill.—Apples: small fruit, Hall-door; large fruit, Bedlorsshire Foundling.

Catalogues received.—W. J. Caparne, Bohais, Guernsey.—List of New Hybrid Alpine and New Intermediate Irises.—Geo. Jackman and Son, Woking.—List of New Plants.—7. Gooden, Betchamp, B. Saul, Clare, Suffolk.—List of Latest New Irises.—The Turb and Co., New York.—Price List of American Seeds.—J. S. Sparrow and Son, Cumberland.—Catalogue of Hardy Plants, Trees, etc.

JOHN R. FLOWER'S CLEARANCE SALE OF RELIABLE PLANTS.

All Good Plants. No rubbish sent out. All carriage paid to arrive fresh to your door.

Cash Price List now ready of reliable Bulbs that will bloom: also Hardy Plants, Roses, Shrubs, Fruit Trees, for autumn planting.

All orders booked next 21 days for Flowering Shrubs, 12s. 6d. value for 10s.; also 25s. value for 20s. This is for shrubs only.

The Best Wallflowers for Spring Flowering, 100 for 3s. 6d., 50 for 2s.; all strong, transplanted plants, and drawn out of seed bed.

100 Wallflowers, in 4 kinds, 3s. 6d.; 50 for 2s.: including the above Blood Red and Cranford Beauty; also Miss P. Carter, primrose; and Ruby Queen, a pretty purple-tinted, smooth, shiny surface, very beautiful; all re-planting, bushy plants.

Blue Forget-me-nots. The best elegant plant for spring beds is the superb Blue Forget-me-not: very compact and intense blue: 50 strong transplanted plants, 2s. 3d., 100, 4s. 6d. We sell thousands of these annually for this purpose.

Cantorbury Bells, in various, mixed. Single and Double, very beautiful, 12 for 1s. 3d.; 24, 2s. 3d.; 100 for 7s.

Herbaceous Foxgloves, best named kinds, 12 in 12 grand sorts, all different and beautiful colours, very bright and large tips, for 4s.; 12 mixed, without names, 2s. 6d.; very good sorts, names lost.

THIS IS THE RIGHT TIME TO PLANT the beautiful MADONNA LILY (or Lilium candidum), before the bulbs start into growth or shrivel. Splendid for garden display among roses, thriving in any soil in the British Isles; perfectly hardy. Can also be used for forcing: 6 Flowering Bulbs, 2s. 3d.; 12 for 4s.; extra large bulbs for forcing, 6 for 3s.; 12 for 5s. Our bulbs are all strong flowering bulbs.

Sweet Violets for winter blooming, rare be pulled and forced in frame or greenhouse for early bloom or planted outside: they are beginning in bloom now. Admiral Arleian, deep purple, very large and sweet single flower, earliest to bloom; Californian, light purple, immense flower, on long stalks, as large as small Pines, extra fragrant; Beroniensis, a very free bloomer, and very sweet, 12 in 12 about 3 sorts, 4s., strong clumps; or any sort separate, same price. Princess of Wales, deep blue, a lovely Vindal, habit like Californian, but superior in bloom, even larger still, and exceptionally sweet, and early bloomer; in fact, the best Violet out; 12 for 2s.; 6 for 1s. 6d.; and the best double Violet, sweet scented, De Farme, lavender, the best winter bloomer, very fragrant, same price; or can be had assorted, same rates. This is the best time to plant Violets; it is all very strong.

Spring Flowers.—Our lovely Pityan has received great praise. Very strong year-old plants; pure white, with yellow eye; this is a grand borderer; very large trusses of flowers: 12 for 1s. 6d.; 24 for 2s. 6d.; per 100, 12s.

Our new mixed Polyanthus, including white, yellow, reds, crimson, and gold-leafed, 12 for 1s. 6d.; 24 for 2s. 6d.; per 100, 10s. These are all very strong. Gold-leafed separate, same price.

The largest White Pink Her Majesty, far above all of any other variety; a marvellous flower, beautifully scented. 6 for 2s. 6d.; 12 for 4s. These are nice clumps, but rootlet cuttings.

Faddington Pink, a real Pink with dark centre; a great favourite for cutting. 6 for 2s. 3d.; 12 for 4s.

Double Potentillas, flowers like velvet, very bright shades of crimson, black, orange, yellow, and striped flowers. 6 for 2s.; 12 for 4s.

Single Pyrethrums or Coloured Marguerites, now in best condition to plant. 6 in good variety, 2s.; 12 for 4s., named; mixed varieties, 12 for 2s. 6d.

New Rudbeckia Golden Glow, blooms like a golden yellow double Cactus Dahlia, produced in great quantities; price now reduced from 1s. each to 6 for 2s. 3d.; 12 for 4s. Roots that will bloom strongly next season.

A Useful and Ornamental Novelty.—The new Strawberry-hedger, grows anywhere; in compact little bushes, about 1 ft. high by 1 ft. across; white Anemone-like flowers, on pretty cut foliage; fruit delicious, about twice the size of a Raspberry; intense scarlet; sunny position required for growth; culture same as Strawberry; it is a herbaceous plant, and increased by root cuttings and suckers; plant now 2 ft. high, 1s. each; 3 for 2s. 6d.; 6 for 4s.; per doz., 7s. 6d.

An Ever-bearing Perennial Strawberry; plenty of fruit on plants now ripe. St. Joseph, runners fruit same season, and it is always in bloom and fruit from July to October. Strong plants, 12 for 1s. 6d.; 24 for 2s. 6d. Small runners cheaper.

Isle of Man Fuchsias.—These are the hardy outdoor Fuchsias, and the largest variety called Riccarton; plant now to establish before winter; makes a capital hardy bed plant for back yards, etc.: 3 for 2s.; smaller, 3 for 2s. 6d.; extra large, 1s. 6d. each; 3 for 4s.

BULBS FOR PRESENT PLANTING.

Grand Hyacinths for bedding, 2s. per doz., mixed colours. Tulips, single or double, mixed, 8s. per doz.; first-class sorts only, 4s. 6d. per 100.

Crocuses, any colour, 1s. 3d. per 100. Snowdrops, 2s. 6d. 100. Mixed Daffodils and Narcissus, for shrubbery, 50 for 1s. 6d.; 100 for 2s. Parrot Tulips, most gaudy colours, and flowers like parrot's beak, 100 for 1s. 50, 2s.; 100, 3s. 6d. Special Hyacinths, large Bulbs for exhibition, all named, 12 sorts, 4s. or 6s.; 24 sorts, 7s. 6d. or 10s.

Special Offer for Camellias and Azaleas, 50 sorts in stock, see Catalogue, gratis.

JOHN R. FLOWER'S CLEARANCE SALE. HARDY & RELIABLE PLANTS.

CASH PRICE LIST now ready (gratis) of reliable Bulbs that will bloom, also spring-flowering Plants, Roses, Shrubs, Fruit Trees for autumn planting.

Special offer of Camellias and Azaleas, for winter flowering, very cheap, will set with bulbs. See Catalogue, 50 varieties in stock.

Bulbs for Christmas and New Year. Bloom indoors. Plant now in pots and bloom in a few weeks.

White Roman Hyacinths, deliciously sweet, 12 for 1s. 3d., 1s. 6d. largest 2s.

Paper-white and Double Roman Narcissus, 12 for 3d.; 24 for 1s. 6d. or 7s.

Scarlet V. V. Thol Tulips. The most brilliant easily-grown winter bloomer, 12 for 3d.; 50, 2s. 6d.; 100, 5s.; also the best early leader, very dwarf.

12 Michacimas Daisies, in 6 quite different colours, 3s., 6 for 2s. among sorts, including Robert Parker (most named), Lady Trevelyan (pure white), and many varieties.

White Everlasting Peas, proved 17m, having bloomed here. Most useful climber for trellis in summer, and flowers grand for wreath work, and almost perpetual bloomers, 3 for 5s. 6d. Also bright rose-colour, 3 for 2s.

Harpallium rigidus Dwarf Sunflower, 3 ft., yellow, dark centre; 6 strong plants, 1s. 6d.; 12 for 2s. 6d.; increase rapidly, nice useful for cutting.

Campanula Backhousei, large white bell flowers, 6 plants, 2s. 3d.; 12 for 4s.; a superb variety of Campanula Persiciflora.

A Grand New Pink, Ernest Ladham, very large, bushy, long, involucre deep crimson, large as a Malheur, in perfection, perpetual bloomer, 3 for 2s. 3d.; 6 for 4s.

A lovely hardy border plant is the Spiraea filipendula, double white flowers, very beautiful, height 6 inches; Fringed foliage, evergreen, quite an amateur's plant. Strong roots, 3 for 1s. 6d., free; 6 for 2s. 3d. Very strong.

Lovely Carnations, in 12 different colours, grand for cutting, named sorts, in 12 shades, 12 for 3s. 6d., including salmon pink, white, Paul's edged, etc.; strong plants.

The Favourite Flower, DOUBLE FRENCH PYRETHRUMS, noble double Aster-like flowers, producing plenty shade of crimson, carmine, blue rose, and pure white, 12 plants, 1s. 6d. To include the fine Mini Blanc, pure white, 4s., not named, 2s. 3d. All strong plants, bloomed well this year, and will grow any where, and last for years.

Borgamotte, sweet scented foliage plants, very sweet, 3 for 1s. 6d.; 6 for 2s., 12 for 3s. 6d.

Physalis Franchetti (the Bellflower flower), 3 for 1s. 6d.; 6 for 2s. 6d.; 12 for 4s. 6d.

White Hardy Marguerites, or large White Perennial Daisies, for cutting; dwarf habit, and grow anywhere; 6 for 2s.; 12 for 3s. 6d. This is the large Chrysanthemum maximum.

Florentine Iris. Sweet-scented, dwarf white Iris, earliest to bloom. Strong roots (not Irish), which spread rapidly. 6 for 2s.; 12 for 3s. 6d.

Golden-Yellow Marguerites (Doronicum Harpur-Crowd), single hardy, and very gay in spring outdoors; bloom all winter if potted in. 6 for 2s.; 12 for 3s. 6d.

Pure White Primroses, Harbinger, 12 for 2s.; 24 for 3s. 6d.; extremely nice; very early.

Red Heron Flower (Ternaria Uvaria). A few of these should be grown by all lovers of hardy plants; strong plants to produce gorgeous scarlet and yellow patches 3 ft. high next season, 3 for 2s. 3d.; 6 for 4s.

New White Honchera. Lovely little rock plant, and good companion to the scarlet variety; 12 for 5s.; 6 for 3s. Very scarce.

Coropsis grandiflora, a beautiful golden-yellow flowering hardy perennial, thriving anywhere and blooming in profusion; very strong plants, 6 for 1s. 6d.; 12 for 2s.

Honchera sanguinea, like a red Lily of Valley, 6 for 2s.; 12 for 3s. 6d.; pure white, 3 for 2s.; 12 for 3s. 6d.

BULBS FOR PRESENT PLANTING.

Anemone fulgens, the brilliant scarlet Wind-flower; no other flower so bright in spring; blooms in February; 12 for 1s. 6d.

Our Grand Dozen Hyacinths for Exhibition, 12 in 12 superb sorts, 4s.; also extra superb, 12 sorts, 6s., first class only.

27 Parrot Tulips.—These are a picture, markings and colours most gaudy, and flowers shape of a parrot's beak; always excite admiration; 2s. 1s. 6d.; 50, 2s. 6d.; 100, 5s.; all the best sorts.

The Largest Tulip in the World is Gesticiana Major, an immense flower, most brilliant, and the crimson blooming in May; also large as an Oriental Poppy when well grown; 24 for 1s. 6d.; also Golden Crown, bright yellow, same price; also Picotee white, with edge of rose, blooming same time, and even less contrast. 12 for 1s. 3d.; 24 for 2s.

ALL SELECTED BULBS, ALL CARRIAGE PAID.

NOW IS THE TIME TO PLANT.

The most beautiful Hardy Climber, and stands A1 on the List.

Pyraeantha Lelandi, free grower, evergreen foliage; white flowers in May, and one mass of orange scarlet berries from August to December; a most beautiful climber. A climber on its residence is now magnificent, and has been admired by numerous visitors. Strong, 1s. 6d.; 3 for 4s. Rapid growers if well watered in summer; this is what all climbers require. Good strong plants, 1s. each; 3 for 2s. 6d.

3 Ampelopsis Veitchii, very strong, for 2s. 6d.; rather smaller, 3 for 2s. 3d. Self-clinging, and turns crimson foliage in autumn; the most popular climber, and sold in great quantities.

White Jessamine, strong plants, not little cuttings, 1s. each; 3 for 2s. 6d. This is a perpetual bloomer all the summer months.

Winter Jessamine, yellow flowers, blooming from December to March outside, naturally, 3 for 2s. 3d.; or 3 Jessamines, assorted, same price.

Wistaria sinensis, long racemes of Laburnum-like flowers, only nature in colour; a fine climber, 2s. each; also 2s. 6d.

Clematis montana, pure white star blossoms, much in demand, 1s. 6d.; 3 for 3s. Good strong plants. Extra large, 1s. 6d. each.

Clematis Flammula, useful climber for arbours or covering roofs of buildings, feathery cream flowers. 3 plants, 2s. 6d.; larger, 1s. each.

Strong Evergreen Honcysuckles, strong growers, 1s. 3d. each; 3 plants, 1s. 6d.

Japanese Honcysuckle, yellow foliage, self-clingers, very bright. 1s. 3d. each; 3 for 4s.

VEGETABLES.

WINTER CUCUMBERS.

To have fruit fit for cutting at Christmas, the plants ought to be put out before the end of October. An earlier sowing in August and planted out as soon as really should provide fruit up to that date. It is a great mistake to crop too soon, not only too soon, but far too heavy. Far better allow a few to mature on each plant and keep the plant growing, though it may be slowly, than allow all that show to remain on and exhaust the plant in a couple of months, and then, it may be, have no fruit for a like time. A good strain of Telegraph is hard to beat, either for winter or summer use, and the plants will at almost every joint show three or more fruits, which if left on would soon destroy the plant's vitality during the dark days of winter. No hard or fast line can be laid down as to number of fruit to leave on. The grower must be guided by the strength of his plants and the daily requirements of the place, my experience being that if two fruits are available each day, one for the kitchen and the other for the pantry, not much complaint is likely to be lodged against him as to the supply. But to do this, plenty of light, also heat, is necessary. The bine should be within a foot of the glass roof, and the plant not pinched until about three parts up the trellis, and not allowed to fruit until the trellis is well nigh covered, one fruit only to mature at a joint. The fruits should be cut when of a usable size and their stems placed in an inch of water, where they will keep plump for three or four days. The soil should not be of a too heavy nature. Fibrous loam two parts, one part leaf-soil, and one part peat, with a little sifted fresh horse-droppings, will support the crop well if a top-dressing of loam and fresh horse-droppings be applied as soon as the roots permeate the hillock the Cucumber was planted in, and a weekly watering with weak manure from the farmyard drainings of the same temperature as the house, which should not register much below 65 degs. during the coldest night, with a day temperature of 70 degs., rising to 80 degs. or a little more with sun-heat. Syringe the foliage gently in the morning about 9 a.m., unless exceptionally cold or wet, and on fine days again about 2 p.m., distributing plenty of moisture about walls and floors of the house several times a day with a view to warding off red-spider, so injurious to this plant. Too close pinching should be avoided during winter, and dust with flowers of sulphur immediately mildew shows itself, and light fumigations will soon eradicate aphides. Very little ventilation is required during the winter months, just a crack at the apex of the house about mid-day when bright for an hour or so, to sweeten the air, will suffice, avoiding cold draughts at all times as well as over-watering at the root, letting the soil show signs of dryness before applying it.

East Devon.

CELERY.

MANY have the impression that this vegetable cannot be grown to perfection without a deal of farmyard or stable-manure dug into the trench below before putting out the plants. That such is not the case was proved here last season by half-a-dozen rows, each nearly forty yards in length, all grown with the assistance of artificial manures scattered between the plants on three different occasions during summer and well watered in afterwards, using a coarse rose to the can the first time going over. I never had better Celery than last winter grown thus, and I always stir the soil between the plants ten days or so after putting out, as the ground gets very hard with treading on when planting and the frequent applications of water. Soot is a fine manure for dusting over the foliage of Celery early in the morning white covered with moisture, add to a great extent wards off the Celery-fly so detrimental to the crop. Early in June this year, when taking out the trench for first crop, I fell short of decayed manure, and had to destroy the winter piece of Spinach for the purpose, and after taking out two good spadefull of soil, I had a good layer of this green vegetable put at the bottom, and a foot of soil placed back over this, giving all a good soaking of water towards evening, and putting out the plants next morning. When this began to decay it appeared just as if a mole had been working in the trench. I had it well trodden down, and a little fresh soil put in as the plants looked a trifle yellow. After this attention they soon altered colour, and now look grand without any other manure except the Spinach.

J. M. B.

NOTES AND REPLIES.

Saving Cauliflower-seed.—It sometimes happens that there turns up an occasional plant or root of extra merit which it is advisable to seed. This occurred in my case with an early Cauliflower some four years ago. I then resolved to save the plant. Although it only gave a few seeds there were enough for a sowing the next autumn. This was done, and the plants kept separate. Last spring out of 500 in one patch, there was not a single rogue. This year I saved eight heads, but from these I shall not obtain half an ounce of seed. I find it is useless to seed Cauliflower in a low garden unless one does so from very early plants, especially in a cold summer like the past. Some heads that formed in the middle of July were left, but these were not in time enough for the seed to be ripened. — J. CROOK.

Planting Cabbages.—It is usually difficult for those who purchase Cabbage plants to be certain as to the variety obtained and its general character of growth. For that reason it is best for those wanting specially early, small-heading varieties, such as April, Ellam's, First and Best, and similar ones, to obtain a packet of seed and to raise their own plants. They then know what they are planting. But even then, if there be no discretion employed, and the plants be put out at the regular distance in rows 2 feet apart, there is great waste of ground. For the varieties named and

other small-heading early ones, rows need not be more than 15 inches apart, and the plants 12 inches apart in the rows. Where ground is scarce they may even go in a little closer. But where room enough for using a hoe freely amongst the plants is allowed, then weeds are more easily kept unlo and the soil is well stirred. After cutting in the spring, if previously well manured, a crop of late Potatoes can be made to follow. — A. D.

Fungus on Seakale.—I should be glad if you would inform me what is the nature of the disease from which the enclosed leaves of Seakale are suffering? They were strong, healthy crowns when planted last winter. A few of the plants are not affected, but have large, healthy leaves, though somewhat devoured by slugs. Should I destroy this plantation and begin again, or is there any other remedy? — F. T. LLOYD.

It is very evident that your Seakale is seriously affected and injured by a fungus, the name of which can only be determined by a fungoid expert. Your best course will be to remove and destroy all the leaves as they fall off, then to smother the crowns and soil about them thickly with freshly slacked lime. Then, after Christmas, cover up the crowns with pots, heaps of ashes, or porous soil, in which the new growths from the crowns can blanch. When these heads are cut lift the roots, destroy them, and crop the ground with something else not of the Cabbage family; Potatoes, perhaps, would be best. Purchase from some nurseryman small crown-carrying roots, or else root cuttings, 5 inches long. If the former, however, cut the crowns off or otherwise they will bolt to flower. Plant these or the cuttings with a dibber on trenched and well manured ground, in rows 20 inches apart. These should then give you a fine lot of Seakale crowns to lift and blanch in a collar, or to leave in the soil and be blanched by covering up.]

Manuring garden.—As a constant reader and subscriber to GARDENING, I should be much obliged if you would kindly advise me as to the best manure for an annual dressing of my vegetable garden? My garden is, roughly speaking, about 40 yards by 25 yards, very rich soil—regular red Devonshire soil. It lies due south, and, being on a slope, is well drained. Last year I dressed it with farmyard-manure, cow and pig, and the results with vegetables have been excellent, except in the case of Potatoes. We had very little disease, but the crop was light. My gardener says we must have something to lighten the soil this year, instead of putting in more farmyard-manure, and I should be much obliged if you would advise me as to how to dress it? My gardener recommends rotten tan, but, after what I have read in back numbers of GARDENING, I fancy tan has no manuring property at all. I should say that the garden, which I took over last September year, has never had any dressing on it but farmyard-manure, so perhaps some kind of artificial manure (if such exists), that would both lighten the soil and manure the ground, would be worth trying. I cannot afford to run to any great expense. — DROVINSAS.

It is evident, seeing that your old garden has been for so many years dressed with animal manure, that a change to some of a diverse nature would be desirable. The soil should be full of humus, and a heavy dressing of lime and soot, half a bushel each per rod, would do great good. If applied, get it dug in during the winter, or you can purchase from some dealer in artificial manures superphosphate (bone-flour) and potash (Kainit), equal quantities, and enough to give a dressing combined of 5 Draper's, getting it put in if it has been well crushed and mixed, and dug in during the winter. The soil, no doubt, contains simple nitrogen, and you can purchase fish-

guano, excellent manure in dry form, and give that at the rate of 7 lb. per rod. Either of these things, and all are cheap and portable, should form capital manure dressings for next season's crops.]

TREES AND SHRUBS.

SNOWY MESPIUS (AMELANCHIER).

WHEN clothed in a mantle of snow-white bloom in early April, this forms a beautiful picture in the spring garden. There are two kinds of Snowy Mespilus—the American *A. canadensis* (here figured), and the European *A. vulgaris*—while the many varieties one sees in gardens may be classed under either of these two. They are all medium-sized trees. The European form is a delightful tree, never failing to produce a mass of bloom, and lasting a long time in beauty. Of *A. canadensis* there are several varieties, including *Botryapium*,

bushes till another year dawns. Among single Roses there is for the garden a goodly number of fine things whose autumn display of fruits is very striking. The Japan Rose, with its great Apple-like fruits, is in the zenith of its beauty in autumn, and nothing could be finer than the scarlet fruits in clusters among the rich yellow leaves. The Water Elder everywhere on the margins of our Sussex woods is borne down with the weight of its profuse clusters of coral berries, and proves that we lose something in neglecting it and giving preference to an abnormal form that has no interest whatever beyond the week or two it remains in bloom. Cotoneasters are at their best in autumn, and there is variety among them, too, with microphylla for clothing banks and rocks; Simoni to associate with other shrubs, its long wands covered with berries, and the tree-like frigida and affinis, which have their berries in great flat clusters at the ends of the shoots. Hollies and Hawthorns are hosts in themselves for

Self-clinging plant for wall.—Please tell me the name of a self-clinging plant that keeps tidy, the year round, of rapid growth, for a wall 3 feet 6 inches high, and 5 yards long, facing the east, in my front garden? I am not particular whether it flowers or not, so long as it appears nice and tidy the year round. The principal object is to cover the wall, which is very conspicuous. State time to plant, etc.—I. HURON.

[The best thing you can plant on such a wall is *Ampelopsis Veitchi* (*Vitis inconstans*), which clings to the wall without any nailing. It is deciduous. Plant at once, giving it some good soil to start in, and see that it has plenty of water during the summer.]

Leycesteria formosa.—At the present time this is one of the most noteworthy shrubs in bloom. The secret of success lies in its having free exposure, so that the wood becomes fully ripened. It is not particular as to the kind of soil it will thrive in, as I have several specimens growing in nothing better than solid clay intermixed with stones. The long bunches of purple or claret-coloured berries which follow quickly on the flowering really enhance its beauty. I have scores of plants springing up in various positions, and which must owe their origin to the deposit from birds, which later on become very partial to the berries. It is recommended as a capital covert plant on account of the berries, of which pheasants are extremely fond.—Y.

The Water Elder in fruit.—From mid-summer to mid-winter this shrub is delightful. It is possible to see its relationship with the Snowball-tree of our gardens when it is in flower, but all through the latter part of the summer, and, in fact, right into the winter, as a berry-bearing shrub it has few equals, and all who see it are struck with its beauty and astonished when informed that it is a native shrub. Bushes by the waterside, as well as those in the woods, are laden with clusters of rich red berries. It richly deserves bringing to the front. Although tolerably common in woods in some districts, this does not minimise its value. In any case, most of those who see it laden with berries by the side of water resolve to obtain and plant it in their gardens. This is the best possible testimony of its beauty and worth.

The Snowy Mespilus (*Amelanchier canadensis*) in an Essex garden.

florida, ovalifolia, sanguinea, and others, though how far these are distinct is doubtful. The Snowy Mespilus grows freely in any soil, but dislikes exposure, especially to east winds, when flowering.

AUTUMN BERRIES.

THE autumn berries and fruits of many plants are so brilliant and beautiful, offering such rich opportunities for special and seasonable effects, that one wonders more attention is not given them, and good things boldly planted for the development and enjoyment of this feature. Special prominence should be given to those things that are full of variety and seasonable changes in preference to the broad expanse of common Box and Laurel or the muddled, tangled masses that pass as ornamental shrubberies in public and private parks and gardens.

The Sweet Brier has several aspects of beauty—the budding of the leaves, the delicate beauty of the flowers, and the after-glow of its hops in autumn. It is a charming plant of all, for they usually hang on the

autumn and winter effects, and few things are more brilliant in the sun on an October day than the Spindle-tree laden with pendulous fruits. From the wild Roses that are happy in heavy clay to the *Pernettyas*, rambling shrubs much varied in colour of fruit and lovers of peat and sand, there are berry-bearing shrubs for all situations, and an abundance of them to enable the planter to use them in a bold, free way.

NOTES AND REPLIES.

Magnolia conspicua for walls.—Recently, when at Hackwood Park, near Basingstoke, I was impressed with the value of this for a wall. In the kitchen garden there is a magnificent specimen against a wall facing east. It is 15 yards long and about 12 feet high, and growing above the wall. So well clothed is this wall that no portion of it can be seen. I have never seen it in more vigorous condition. In large gardens many walls may be used for growing the fine trees and shrubs that are now devoted to lawns and such things.—J. CROOK

WATERING.

I HAVE a small garden in which I more especially delight to grow a few standard Roses and clumps of Sweet Peas, but I am a busy man, and, when a long spell of hot, dry weather comes, my brief leisure time is more than fully occupied in watering. Early in the spring of this year I picked up in the local market for a few shillings a small, second-hand garden engine, and I was delighted one day, when the end of the hose pipe fell to the ground, to notice that it almost immediately acted as a siphon. This happened during the few hot days we had early in the summer, and my Roses were beginning to look a little unhappy, so I promptly filled the engine and wheeled it close to a Rose-tree, laid the nozzle of the hose at the root, and went in to breakfast. Before I left home for my office the engine was empty—the water had gone straight down to the roots without disturbing the soil at all, and the patch of wetted surface was not larger than the crown of a hat. I had time to refill the engine, take it to another Rose-tree, and again leave it with the same result. This meant half-a-dozen or more Roses and clumps of Sweet Peas well watered each day, in addition to the ordinary work with the water can, and I was thoroughly pleased with my discovery. Perhaps some of your many readers, who appreciate the difficulty (when time is limited) of watering effectually, and without making an unsightly mess of the ground, may be able to make use of this hint, and, if they can and do, I am quite sure they will not regret it. S. H. W.

Tufted Pansies.—Many people imagine that these cannot be propagated after about the middle of October. As a matter of fact, the best cuttings are often produced long after this time, and up to the end of the year. I have struck them in cold frames in sand and loam, or in the border, where some little protection could be given them in bad weather. Given an opportunity of getting cuttings, no one need be short of plants if they are put in for upwards of two months yet.—T. W. JENKINS.

PLANTS AND FLOWERS.

OUTDOOR PLANTS.

THE VIOLET.

Nor in the rich sunlit pastures, the home of the Daisy and Buttercup, do we find the Violet, but rather on some sheltered bank, nestling in leafy copse, or else reposing at the foot of some protecting monarch of the wood. A marked preference for moderation of temperature and other conditions is shown by the Violet in its native state, and for this reason the orchard is often a most suitable place for the cultivation of this flower, affording as it does protection both from the severities of a hard winter or the scorching sun of a hot summer, yet permitting welcome rays of sunshine to filter through the leafless branches of the trees. Coming to a choice of

KINDS, the somewhat limited range of colour once obtainable in the Violet has of late years

is the old favourite Czar, perhaps the hardiest of all Violets, but Luxonne, a handsome variety of large size, and having somewhat pointed petals, is an advance in this direction, and, with Wellsiana, ought to be given a place in every garden. One or two more varieties amongst the new sorts may be mentioned. In St. Helena we have a variety producing blooms of a delicate but somewhat undecided light blue tint. California, a well-known variety, introduced from America some ten or twelve years ago, certainly marked an advance on the Violets of previous times, but in point of quality and quantity of blooms it cannot be compared to V. Princess of Wales, which may be considered as a standard of its type. In the

CULTIVATION of the Violet, yearly and early division of the plants is important, even though one may reluctantly have to sacrifice a few of the later blooms. To allow plants to become crowded and weakened by the rapidly growing foliage of spring, or to defer planting until too late for the young rootlets to become

maintaining the foliage in a healthy state. If natural shelter should be absent, any trouble spent in shading the plants during hot weather with Laurel or other branches will be well repaid. Frequent weeding and light surface working of the soil are essential, the latter promoting a healthy growth and checking too rapid evaporation in times of drought. Avoid by all means the error—a not uncommon one—of those would-be cultivators whose idea of growing the Violet is to plant it and “leave it alone.”

HENRY T. HERRON, F.R.H.S.

Donaghadee, Co. Down.

FLOWERS IN SWITZERLAND IN JUNE.

UNFORTUNATELY, I am not a botanist, only a flower lover, and I shall describe, as well as I can, the flowers that pleased me most, in the hope of interesting others like myself.

Very early in the morning near Pontarlier I looked out and saw quantities of white Narcissi, the first I had seen growing wild, look-

Violet Princess of Wales. From a photograph by Miss Ohichester, Arlington Court, Banastaple.

been greatly extended, and while I still prefer the deep rich tint of La France, or the lighter and more transparent shade of Princess of Wales, yet for those who desire a greater variety of colour there is ample choice. Amiral Avellan, the claret-purple blooms of which, gradually increasing in their ruddy tinge as the season advances, brings to mind Milton's term of “the glowing Violet.” In point of size this variety cannot be compared to Victoria Regina or the kinds already mentioned, but nevertheless a place should be given it wherever Violets are grown. Besides being prolific and hardy, and probably one of the most rapid of all Violets to multiply, it retains the distinct and characteristic habit of the older V. odorata in its irregularity of shape rather than the more evenly formed blooms of recent introduction, some of which seem to vie with the Pansy in roundness of outline. Anent this latter point, I have gathered, from well-grown outdoor plants of Princess of Wales, blooms, which, when pressed down on a florin, were sufficiently large to completely cover it. One of the earliest still to flower in the autumn

properly established before dry weather sets in, is to court disaster. The soil, too, demands attention. This should be deep and well-drained, and while avoiding over-richness the ground must have an ample store of humus, supplied preferably by a generous admixture of leaf-mould rather than by any stimulating manure, the effect of which induces a soft and too rapid growth of foliage, often resulting in unripened crowns carrying but few or poor blooms, besides leaving the plant weak and susceptible to various diseases and attacks of insects. In heavy or retentive soils a liberal addition of sand is often advisable or even necessary, and, where obtainable, mortar-rubble is always appreciated by the Violet. If manure is used, it should not be fresh—nothing equals well-decayed leaf-mould—but, in the event of this being scarce, spent hot-beds may advantageously be utilised as a substitute for the latter, or to augment deficiencies. A natural shelter for Violets is a hedgerow, somewhat bare near the ground, in which the plants get currents of air, which are beneficial in keeping down attacks of red-spider and

ing lovely in the dewy Grass, with a background of Pine-trees. Nearing Lausanne the meadows seemed ready to be cut for hay, and were full of flowers. I remarked especially a very showy purple-blue flower, with spikes about a foot or more in height, and a beautiful large yellow Daisy growing singly. The purple-blue flower was ubiquitous in the lowlands and semi-highlands of the Rhone Valley, Val d'Illiez, Zermatt Valley, etc., and I noticed it also coming back through France. It had a square stalk, and was evidently a Salvia.

I never saw the big yellow Daisy except from the train, so could not find out what it was, as I could not see its leaves. The most conspicuous flower besides the Salvia and the yellow Daisy was a beautiful rosy-pink, spiked Vetch, which was very abundant in the lowland meadows. It was very hot on June 5th at Ouchy. All the Roses, and many trees and shrubs that one only sees in the south of England, such as Paulownias, Rose Acacias, etc., were in full bloom. Along the margin of the lake on the esplanade I admired the groups of flowering shrubs and dark-leaved Filberts,

Original from

Prunus, etc. There were some beautiful and uncommon Spiræas and Weigelas. We went to Bouveret next day, on our way to Champéry. The villages by the lake were bowers of flowers, the houses covered with Roses, and the quays shaded by flowering trees. Above Montreux, and towards the Rochers de Naye, the hills seemed as if covered with hoar frost in places. With the glass I could see that they were patches of the white Narcissus. I heard afterwards that the Feast of the Narcissus was held about a month later than usual this year. At the usual time there was no sign of the flowers. Waiting at Bouveret for the train, I had a good opportunity of examining the purple Salvia, which was very fine there. I drove from Montreux to Champéry, through the beautiful Val d'Iliez, rising all the time. As soon as I got above the vineyards the fields and banks were covered with the flowers. A large purple Geranium grew among the Grass all through the valley, contrasting with a creamy-white umbelliferous plant that was in such profusion that it looked like foam among the green Grass. The hay must have more flowers than Grass in it. There were several sorts of Campanula in it (I recognised *C. glomerata* and *C. rhomboidalis*); blue round-headed Phytomas, a greenish-white sort; Astrantias, pink and white; a very fine purple Orchis, creamy-white Habenarias, dark wine-red Columbines, tall, feathery mauve Plantains, large blue Mountain Cornflowers, the before-mentioned rose-coloured Vetch, and a very pretty rosy-pink umbelliferous plant, besides many others. On the damp, rocky banks Spiræa Aruncus was in bud, and the two-flowered alpine Honeysuckle. At Champéry the valley is rather narrow and shut in by the Dent du Midi and other high mountains. Down by the river, the Vioza, the Ferns are wonderful. I was told that in one place 15 species can be found in 50 yards. Under the trees and in the open glades by the river, *Trollius europæus* was very fine, also the purple Tooth wort (*Dentaria ligistata*) and its white form, *Dentaria pinnata*, handsome plants, something like *Honesty*, but with prettier leaves. The meadows were full of the leaves and seed-vessels of *Colchicum autumnale*; these were abundant wherever I went, except in very high places, and must be a wonderful sight when in flower. I found *Asarum europæum* growing round damp rocks in the woods with its insignificant brown flowers. The ground was carpeted with Wood Anemones dying down. A native told me they were blue ones, but they looked like our familiar white ones. The little yellow *Viola biflora* was very common everywhere. The red-berried Elder (*Sambucus racemosa*), which was in flower wherever I went, is very beautiful in the autumn. The weather was wet and disappointing while I was at Champéry, so I did not walk far enough to get St. Bruno's Lilies, Lilies of the Valley, and alpine Roses, though they were found by others. There were very fine clumps of the yellow Gentian and *Veratrum album* coming up in the fields. Our common English Daisy was not to be found, though Buttercups of many sorts were abundant, including *Ranunculus nemorosus*. There was a larger Daisy on a long, slender stalk in damp places, called *Bellidistrum Micheli*.

On the 14th of June I left Champéry, and went to the Riffel Alp. The vegetation was not nearly so forward in the Zermatt Valley as in the Val d'Iliez. Going up in the funicular railway to the Riffel Alp I was delighted to find *Anemone sulphurea* in the Pine wood. Directly I arrived I went down into the wood and found it carpeted in places with *Anemone vernalis*, with large, drooping, downy buds of many colours, varying from coppery-rose to purple and white; and here and there, under a shrub, one fully open, a lovely white star, with centre of golden stamens. Of all the lovely flowers I saw, these pleased me most, and they were everywhere—out on the bare mountain sides as well as under the trees, varying in size and colour according to their position. The flowers of *Anemone sulphurea* were not fine; I have found them in other parts of Switzerland quite double the size. Round the Hotel Riffel Alp the snow had melted, though there was plenty even lower down. The Grass was white with Crocuses and a white *Primula* (G. J. G.).

like leaves, probably *Ranunculus pyreneus*, with here and there patches of large purple Violas and tiny *Schizanthus*. Next morning I went up by the railway (the highest in Europe) through deep snow cuttings to the Gorner Grät. I walked from the station to the top, through a narrow, winding cutting in the snow, the sun blazing overhead. Between the restaurant and the railway station was a little patch of bare rock where the snow had lately melted, and on it I found several tiny plants. A beautiful wine-purple flower was out on a sort of grey Moss; in some of the crevices I found it many times afterwards in different places, sometimes pale pink, sometimes deep purple. The flowers seemed very large for the size of the plant. It was *Saxifraga oppositifolia*. Up on the mountain behind Riffel Alp all sorts of delightful little plants grew. I found fresh ones in flower on each sunny day. There were *Gentians*, large and small, *Gentiana acuminata* and *Gentiana vernalis* (the latter such a lovely sky-blue), *Anemone vernalis*, *Anemone Halleri*, *Androsace carnea*, *Androsace obtusifolia*, *Androsace Vitielliana*, with flowers like tiny golden *Primulas*, and many sorts of *Sedums* already pointing up for flowering, from a large brown-tipped one, like our English Houseleek, to the tiny cobweb *Sempervivum arachnoideum*. In damp places the ground was pink with *Primula farinosa*, with here and there a white one. Two *Geums*—*Geum montanum* and a smaller one—grew on the hillside, and *Draba aizoides* made it yellow in many places, and it was about everywhere. *Daphne Mezereum* grew in hollows among broken rocks.

One day I walked to the Schwartz See—a good climb down and up again from the Riffel Alp, as it is on the flank of the Matterhorn. The valley between was blue with Forget-me-nots and yellow with Globe-flowers. A little higher up, the rocks and banks were gay with *Cheiranthus alpinus* and with purple alpine Asters, very deep in colour. I also found *Bisectella* and many other flowers. In the shady cracks of Mossy rocks there were colonies of rosy mauve *Primula viscosa* and of a small white Iberis. Higher again, the guide showed me some plants of Edelweiss, but it was not in flower. In a few places I found *Lloydia serotina*, but it was not common. There were very deep blue *Veronicas* in the valley, and fine blue *Globularias*. In the Pine-woods there was thick undergrowth of the alpine "Rose" (*Rhododendron ferrugineum*), not yet in bloom, and *Bearberry*, with white and rosy-pink *Arbutus*-like flowers. Hanging over a damp rock on the hillside was a sheet of *Dryas octopetala* in full bloom, almost a yard in length.

During the nine days I was at the Riffel Alp the flowers came out very quickly, and before I left the ground was blue with *Gentians* in places, and there were quantities of the sweet-scented purple Violas. A tiny *Azulea* (*A. procumbens*), with pink flowers, covered the stony ground in patches on the mountain-side.

Down at Zermatt an interesting alpine garden is being made. It is already full of alpine plants, but very few were then in bloom. The most striking was *Atragene alpina*, with its graceful wreaths of purple or palest pinky-cream Clematis flowers. There was a lovely mauve *Androsace*, but I found it was a Himalayan species.

When I left on June 23rd, going from Zermatt to Visp, the meadows were nearly as flowery as those at Champéry had been. In places there were quantities of a bright magenta Labiate, and the Scabiouses were bright pink instead of mauve. On the grey stony banks *Saponaria ocymoides* grew in resy cushions. Down the Rhone Valley and through Switzerland and part of France the purple Salvia was as gay as ever; it evidently has a long blooming season. Crossing France, the country was not so flowery, except about Pontarlier, where there was still plenty of white Narcissus, Globe-flowers, purple Columbines, etc. Between Pontarlier and Paris and on to Calais it was very hot, and the great stretches of dark red Poppies and blue Cornflowers were gorgeous. Where they were mixed the result was a wonderful purple effect. During the whole journey from Zermatt to Calais I only saw two small patches of Honeysuckle, perhaps because there are so few hedges. E. J. L. (E. J. L.)

HOW NOT TO LEARN GARDENING.

TO THE EDITOR OF "GARDENING ILLUSTRATED."

SIR,—In the current number of one of your contemporaries there is a review of a book called "Villa Gardens," in which the following luminous statement occurs:

"Less than twelve months ago on taking possession of a new house with a piece of ground of unusual size for a suburban villa I thought it wise to consult some of our well-known authors in order to get an idea of what to do for the best. I had heard of Kemp's well-known 'How to Lay Out a Garden,' but, being out of print, I could not come across a second-hand copy. I have several hundred gardening books in my library, but in not one of them there such a thing as a design for laying out a garden, great or small. At this juncture a friend lent me Mr. Robinson's 'English Flower Garden,' in which there are several plans, but these are mostly of large gardens in the country. However, I got from that work a hint which helped me considerably in my difficulty; but it is an expensive book, and in many cases would answer little or no purpose, especially in small gardens of from 50 to 100 feet in length, such as the suburban ones usually gets allotted to him."

That a man with a hundred gardening books in his library should not feel competent to lay out a garden is less surprising than the supposition that the possession of gardening books is in any way related to a capacity for making good use of them. A man with such a thirst for plans is, to my thinking, in a bad way. There are too many garden plans in books. Knowledge of plants is the first thing needful to plan gardens large or small. The writer's naive admission that he got from "The English Flower Garden" a hint which helped him considerably, shows that unconsciously he has a perception of what can be learnt from a good gardening book—namely, the wit to make your own plans. The instructive essays of "The English Flower Garden" must, I imagine, leave most readers with a sense of added power and insight that would be well satisfied with the slavish imitation of any of its plans. Small gardens are easier to make than large ones, and the remedy for the painful monotony of villa gardens, which the writer complains of, is not the study of plans, but better education and the resulting finer perceptions. The essays in "The English Flower Garden" are an education in themselves. I doubt if the most diffident "suburban amateur" who absorbs them will think he has bought his knowledge dearly, and experience leads me to believe that the many cases for which the book "would answer little or no purpose" will be sought for in vain.

OWNER OF A SMALL GARDEN.

CARNATIONS FROM CUTTINGS.

ONE cannot agree with the views of Mr. J. Green, at page 349, as to rooting the above from cuttings, and, in particular, the method set forth on the very laudable score of labour saving. It is shown in the note referred to that three distinct operations are necessary quite apart from the very essential one of "taking the cuttings in the usual way." The three items are "trimming," "splitting the stems," and "inserting a small stone to keep the ear open." Provided labour saving is really an essential item in the matter, all three are quite unnecessary; indeed, the last two are not only very tedious, but a deliberate waste of time rather than that it is advocated as a labour saving method. It were quite easy to make three cuttings to the ordinary joint while these three items are being carried out, and amateurs, equally with professional men, have to study time and other things. The only really quick and certain way of treating cuttings in the open is as follows: From any large tuft that contains many growths that could not be layered in time, let anyone take and strip off from the parent plant, each with a heel attached, as many pieces as are required. Taking the growth in the thumb and forefinger of the right hand, and giving a slight, yet sharp, downward pull, the piece will come away with a perfect heel almost every time. Now make a little trench as though setting a Box edging, and so deep as to admit the so-called cuttings being buried up to the leafy tuft, and insert them without trimming, stem-splitting, or stone wedges. A little pure sand or very sandy soil may be put in each trench at option, and may depend on the nature of the soil. There is, however, no need for any prepared bed of soil at all. As the cuttings are placed in the trench, and while held in

sition by the left hand, draw sufficient soil with the right hand to keep them fairly erect, and, finally, finish off with the spade while also repairing a second trench. A good gentle tread with the foot when the trench is two-thirds filled with soil is a necessity. Not only is this a quick way, but a way also that ensures settings of the size of layers, and quite large enough for spring planting. By this means several hundred may be inserted in an hour, whereas, by the method Mr. Groom suggests, would not be possible to take and make one

pecker. You may wonder, but in the summer (so-called) I saw one pecking away vigorously at about 4 a.m., though I confess I have not seen another since. True, I do not often look out as early as that, and now it may be that I shall not see the excavator, as the hedgehog is a late evening and night feeder. I know I have hedgehogs here.—C. R. S.

LILIUM AURATUM AT KEW.

In some few instances known to us there are permanent clumps of this Lily growing and flowering well each year. Some of these occur at Kew, where this fine Lily does well planted

derived from planting the bulbs in these beds of shrubs are suitability of soil, freedom from stagnant moisture, protection to the young shoots in spring from frost, and, not least, the protection which is afforded the stem-roots of the Lily from the heat of the sun in summer. From the cultural side these are most important, and, being afforded by the planting of the two things in one bed, are not merely good from the standpoint of artistic gardening, but equally so economically.

In the planting of this Lily it is well to avoid manure of any kind below the bulbs; indeed, it is not wanted where a good depth of suitable soil is present, and such soils as go to make a good Rhododendron-bed are the most suitable for the Lily in question. Where no such bed is at hand, a peat and loam mixture, with much sand, is excellent, or a very sandy loam is equally so. Where close soils obtain, it is well to remove a portion and replace it with material of greater porosity. In this way, and by covering the soil almost wholly with sand, good drainage is maintained about the bulbs. This is perhaps as far as the cultivator can go—at least, until some method can be devised for shipment that will dispense with the wholesale root mutilation now practised.

There are several forms of this Lily that in noble appearance, in massiveness of their flowers, and in purity in some instances quite surpass the typical kind. These are known by the following distinctive names: *Platyphyllum*, with very large and massive flowers, perhaps the noblest form of all; *rubro-vittatum*, the red-banded Lily, very striking; and those chaste and beautiful white forms known as *virginale* and *Wittel*, the former of which is generally regarded as the white form of *platyphyllum*. All are beautiful and fragrant, and well worth the attention of the gardener. Dry bulbs may be planted at any time until March, or even later than this, and, if only to assist the great mass of stem-roots that are produced, it is well to see that the bulbs are set nearly or quite 6 inches deep.

NOTES AND REPLIES.

Tropæolum canariense sportng.—I am sending you a flower to ask your opinion. I have grown *T. canariense* for over 20 years, and it is the first time I have seen the flower change to something like a *Hop*. I also enclose you a piece of Canary Creeper raised from same seed and at the same time. You will see the seed on the *Hop*-like plant is quite different from the original.—JESSIE ROWLANDS.

[A very curious and interesting malformation, and one which you should endeavour to perpetuate.]

Petunias.—I shall be much obliged if you will give me the benefit of your advice on the following: Do Petunias usually flower well in a loose, sandy soil? I have had several planted in my garden, and those in good, light loam are about three times the size, but few blooms, of those in the sandy soil, which are full of bloom. If sandy soil is the best, would you enrich it or leave it rather poor? I have a quantity of manure offered me which is mixed with sawdust. Do you think it advisable to use this as a general fertiliser?—M. A. F.

[The spots chosen for Petunias should be open and sunny and the soil deep and rich, for in low, damp situations they mildew and canker as soon as the first cold nights of autumn set in. They produce a charming effect in masses, and are well suited for large vases or baskets of mixed plants. We would not advise you to use such manure, as it will cause fungus.]

Planting borders.—I have a border facing south which is fully exposed to the sun and well sheltered from north and east winds; there is a hedge at the back of it. The gardener describes the soil as "gravely peaty." Are there any Rose-trees that would do there (long-flowering ones preferred)? If Roses would not do there, could you kindly tell me of one or two perennials or annuals that would perhaps do? There is a very clayey damp border, facing west, in an angle of the house. The border is up against the house and sheltered from the north wind; parts of it are exposed to the sun for a few hours every day. Would Irises do there?—SVERE P. BERNARD.

[We do not think that Roses will do much good in the soil described as "gravely peaty," but such hardy things as *Coreopsis*, *Gaillardia*, English and Spanish bellious Irises, *Astragalus*, Crown Imperials, *Heleniums*, *Happaliums*, Day Lilies, *Pyrethrums*, *Lilium unbelatum*, *L. croceum*, *L. tigrinum*, *Gaetonia candicans*, *Michaelmas Daisies*, *Tritomas*, and such plants would do quite well. In the damp and clayey border many things would do, and also Irises of the Flag section. *I. Kumpferi* should be chiefly selected. Of the former you should keep to the strong growers, like *pallida*, *virginica*, *White*, *Spargene*, *Chelles*,

Golden-rayed Lily grown properly among peat-loving shrubs. Kew, autumn, 1902.

hundred cuttings. Again, Mr. Groom has only rooted cuttings in the end in any case, while the pieces I have referred possess all the bulk of layers. Most of the ordinary border kinds root well in this way, as also the Malmaison section, when good open air material is available. There is nothing new in the method—in fact, the idea is an old one. E. JENKINS, Hampton Hill.

in the beds among the Rhododendrons. This is the ideal home for this Lily, and though it cannot be said the conditions are absolutely essential to success, yet so much greater is the success attained when thus associated with shrubs and the companionship of roots below ground, that it is the method followed by those who desire to succeed with it. Thus it is we see each year a goodly supply of this Lily in the Rhododendron-beds on the lawn at Kew. Fresh plantations are made from time to time, however, so that a good display is maintained at flower-time. Some of the advantages

Holes in lawn.—I am glad to note "Inglebrook's" suggestion as to these being the work of a hedgehog. It may be so. I have found several, mooring after dinner, to some time, and have attributed them to a green wood-

Dr. Bernice, Mme. Chereau, Mrs. Chas. Darwin, while strong seedling clumps of the other group will be best. You could also plant *I. sibirica orientalis*, a very fine plant nearly 4 feet high, and graceful withal. If you wish for other good plants, you should try the herbaceous *Phloxes* in variety, *Spiraea Aruncus*, *S. venusta*, *Narcissus poeticus* fl. pl., *Lenten* and *Christmas Roses*, and the like. There are many other things that could be named, but the above massed together would make a fine show. Indeed, the three sets of *Irises* would form a very satisfying group, and where irregular groups are valued these should be favoured: indeed, the foliage is handsome at any time. If you plant you should think about it soon, as we by no means favour planting *Iris Kamperferi*, for example, in mid-winter.]

Lilium auratum failing (F. M.).—No Lily yet known to cultivators has so long remained a universal favourite as this. But with all its beauty, its noble appearance and unequalled fragrance, it disappoints quite a large number of those who plant it year by year. Like many other good Lilies this comes to us from Japan each year, for the simple reason that we cannot grow it in this country. This may or may not be the fault of the British, though in my own mind I am fully persuaded that the ingenuity of the Japanese would also be taxed to the utmost were they to try and cultivate successfully with what little life there is remaining in the bulbs of *Lilium auratum* as they reach this country. Externally there is an amount of apparent soundness in the fairly hard dry bulbs, and we obtain a fresh supply in the full hope of success. The more notable successes, however, only carry one to the flowering stage of this fine Lily, and if for our outlay and trouble we obtain one good flowering we must be fully satisfied. Large numbers of the failures are attributed each year to soil, insufficient drainage, fungus through starting the bulbs in Cocoa-fibre, and other causes, but these are more or less imaginary, and all are beside the mark. The chief cause of the loss of hundreds of thousands of bulbs each year is the direct outcome of a barbarous method of dealing with the bulbs in their native home prior to preparing them for shipment to this country, and consists in the first place in the bulbs being denuded of all their roots. As this Lily produces but the one set of roots below the bulb, the bulb is thrown upon its own resources for its subsequent growth and flowering, and virtually exhausts itself in doing so. It is in these circumstances therefore that those who wish to succeed must obtain fresh supplies of the bulbs each year, and fortunately for the vast throng who admire this kind the price is not at all high.

INDOOR PLANTS.

SPRING-FLOWERING BULBS IN POTS.

A GREAT point in the pot culture of *Hyacinths* and other bulbs is often overlooked—namely, a good supply of roots before placing them in a forcing-house, or otherwise putting them under glass to flower. To ensure success this is absolutely necessary. We often hear those who sell the bulbs blamed when really the grower is at fault. We have noticed persons potting up *Hyacinths* and *Tulips* and at once standing the same in a forcing pit, with the result that they either rotted or refused to flower. It is necessary that the bulbs named, with *Narcissi*, which are not the least important among spring flowering subjects, should be potted without delay, and a lengthy season be thereby given to become well rooted previous to coming into bloom.

Soil.—*Hyacinths*, etc., like a rich, open compost. Use a mixture of one bushel of loam, half a bushel of well-rotted cow manure, and a like quantity of road sweepings, to which last bulbous plants are very partial. A 5-inch potful of soot may be added to the above quantity of soil with capital effect. The soil, if at all inclined to be pasty, may be turned in the sun to dry, and if very dry, water should be sprinkled on it whilst being mixed.

Potting.—The size of pot used for one *Hyacinth* bulb is the popular 4 1/2-inch or 5-inch. This is not only a convenient size, but

large enough for exhibition. Three *Hyacinths* placed in an 8-inch pot answer well for conservatory decoration. *Tulips* for exhibition are generally grown three bulbs in a pot. For the decoration of vases in rooms three or four bulbs are often placed in the smaller 4-inch pot because of its convenience. In the case of *Narcissi* the bulbs are put into the pots as thickly as possible. Sometimes three bulbs of the *Polyanthus* kinds are sufficiently large to fill one 6 inches in diameter. When potting use one good crock over the hole and then a portion of the rough part of the compost, and fill the pot so that about half of the bulb is on the surface. Do not fill the pot with soil and then push the bulbs into it, but make a hole to receive the same with the fingers, and press the soil firmly around it. If the former be done the compost is too firm, and when roots are made they sometimes push the bulb out of place, when injury to it becomes easy. After potting stand them on a firm bottom in frames, so that the lights may be readily put on in the case of continued wet weather, when there is a likelihood of the soil getting solidened. It is a good plan to invert a small pot over the bulb of each *Hyacinth*. This will keep the bloom-spike clean and often prevent its rotting, but with *Tulips* and *Narcissi* such a precaution is not necessary, as these are not so ready to show bloom before leaves. Cover the whole with about 4 inches of Cocoa-nut-fibre or sand. Do not on any account use ashes. Sulphurous matter resting in these may be the cause of utter failure. The bulbs should remain in the dark until the end of the year. This does not, of course, apply to the early Roman among *Hyacinths*, the *Piper-white* among *Narcissi*, or *Tulip Due Van Thol* of that ilk, which may be laid in flower before that time, but to the general list of varieties, which are much better if not forced into bloom by the aid of fire-heat. In January take the pots from their covering and put them into other cool-frames, but insure them to the light and air in a gradual manner, and in the meantime carefully protect them from frost. When the young growths are well used to these, the pots may be stood on greenhouse shelves as near as possible to the glass, where abundance of air may reach them and where the temperature is kept to between 40 degs. and 50 degs. In this position the leaves will be sturdy. Water may now be given if the soil is at all dry; but although *Hyacinths*, for instance, develop in water alone, it must be sparingly given when the roots are in soil and there is little top-growth. As the growth develops there will be greater calls for moisture, and when the blooms show, it is not an easy matter to over-water *Tulips* or *Narcissi*. From the time the flowers show colour give the plants manure-water. If treated as advised, there will be abundance of roots, and they will be in a condition to respond to feeding. Sulphate of ammonia, used at the rate of an ounce to 3 gallons of water, may be employed with safety, and is a first-rate stimulant: so also is root-water.

FORCING HARDY PERENNIALS IN POTS.

What hardy perennials do you advise starting in heat in March, and transferring to a cool-house or frame as soon as they are up? The following are some of those I am thinking particularly of: *Adonis vernalis*, *Anchusa italica*, *Anthemis*, *Arenaria*, *Armeria*, *Aster* (dwarf kinds), *Aubrieta*, *Campagna* (dwarf), hardy *Cyclamen*, *Delphegium*, *Erigeron*, *Enous*, *Feracrus*, *Gypsophylla*, *Iberis*, *Incarvillea*, *Linnaria*, *Lobelia*, *Lycchnis*, *Mimulus*, *Monarda*, *Phlox* (various species), *Potentilla*, *Pyrethrum*, *Saxifraga*, *Scabiosa*, *Sedum*, *Thalictrum minus*. I am afraid this is a very long list, but I wanted to give you a good idea of the perennials I am thinking of.—Devon.

[Some hardy plants may be forced with impunity, while others not only detest artificial heat in any degree, but even object to glass i.e., cold-house or cold-frame. This may seem an exaggeration, but it is not so, and the plants make better progress in the open air. We do not agree with your method in this matter, simply because the principle is wrong. You may start certain plants in a cold-house, well ventilated, if you will, and introduce them to increased warmth at a later period, but to start them in heat and put them into cool or cold quarters as soon as you have in heat excited them into growth is wrong. If you really want some hardy plants in advance of outdoor ones, the way

to succeed is to pot up in autumn, plunge in ashes or in open frames in winter, and introduce to cool-house and heat by easy stages. You will note this is the very opposite of your plan. Not a few plants are benefited by being flowered in a cold-house, and if the subjects are well established in their pots or pans, bloom well. In this category we include all the early bulbous *Irises*—e.g., *reticulata*, *Histrio*, *Heldreichi*, *persica*, *Bakeriana*, *huxleyoides*, *Danfordia*, etc. *Leucojum vernum*, spring-flowering *Cyclamens*, *C. Coum*, *C. Atkinsi*, etc. *Adonis vernalis*, *A. amurensis*, *Megasea cordifolia purpurea*, *M. ciliata*, *Saxifraga Boydii*, *S. Bursariana* and its variety *S. apiculata*, *S. oppositifolia* in variety, *Morisia hypogaea*, together with pans of *Chionodoxa*, *Muscari*, *Snowdrops*, and the *Belle-colliums*, or *Hoop Petticoat Narcissus*, would form a most interesting array without forcing, and, therefore, without risk. Then a list for succession may include *Anthriscus* in variety, *Lycchnis alpina*, any of the *Primula* *Sieboldii* group, also *P. rosea*, *P. denticulata*, *P. cashmeriana*, *Corydalis thalictroides*, *Thalictrum adiantifolium*, *T. minus*, *Tiarella cordifolia*, *Iris pumila* in variety, *I. nuda*, the *Doronicums*, *Hepaticas*, *Gentiana verna*, *Saxifraga Cottleton*, *S. longifolia*, the alpine *Phloxes*, and later on the *Columbines*, *Flag*, and other *Irises*, *Candytuft*, *Gentiana* *sealyi*, and many more. All of these, by introducing them successively into the cold-house from the frame or pit, would keep up the procession of flowering till there were many buds in the open. If greater variety is desired, some of the more showy *Trumpet* *Davallias* would supply the want. What you should embrace is the naturally early flowers of spring and get these into good tufts in pans or pots as though specially grown for the purpose. And what you have to avoid is that large number of late summer flowering things—*Monarda*, *Lycchnis*, *Scabiosa*, *Potentilla*, *Lobelia*, *Anchusa*, etc., with *Campicels*, *Delphiniums*, *Eremuri*, *Pyrethrums*, etc., the last three of which cannot endure glass-structures at all. If you work on these in a cold-house in spring may be full of bud-treasures, and in early summer repeat with more showy subjects. It is a plan too calculated to save your heat and not a little disappointment into the bargain.]

NOTES AND REPLIES.

Begonia Martiana gracilis is a very beautiful kind now in bloom. The fine specimen I dissected and illustrated in *Indoor*. The leaves are of the deepest possible green, which brings into bold relief the clear purple coloured flowers, shading off to white towards the base of the segments. They are about the size of a halfpenny and borne freely.

Growing bulbs in a glass bow.—When do bulbs grown in water or deep glass, according to directions in *GARDENING* of October 18, have commenced to grow, where should they be kept till they bloom, and at what degree of heat?—G.

When the bulbs have well rooted, stand them in a sunny window. They ought to have been in a dark board until they had formed plenty of roots, as with these they will certainly fail to develop the flowers.

Lotus poliorhynchus.—Can any of your readers tell me how this plant is cultivated, and whether it is an annual, biennial, or perennial? I have several fine plants in pots raised from seed this spring. They have not yet flowered, and are now shedding their hair-like leaves. Might they be cut back and kept dry all the winter under glass, or kept growing? I have seen it hanging over walls in Tenerife, where, I suppose, it is left out all the winter.—G.

[This is virtually a greenhouse under-shrub, therefore of perennial duration. The plants should be kept growing steadily all the winter. To dry it off after the manner of bulbous things would mean to kill it. At the same time a certain degree of root dryness in the winter season has a very sweetening effect upon the soil, and in turn keeps up a healthy root action. As the plants were only raised this spring, little pruning should be required. Shorten the longest trails now, and in mid-January or later give a little shift to the plant, which, with liberal treatment, should flower during the coming year.]

Davallia falling.—I will be much obliged by information as to the cause of a *Hare-foot Fern* falling so much. The root appears quite healthy, but the leaves soon go like the enclosed. What is the best treatment for these Ferns?—BETA

[The frond you send is evidently that of one of the deciduous *Davallias*, but it is impossible to say what is the name from such a specimen. It has, however, been attacked by thrips and red-

older. During the resting period the deciduous varieties should not be allowed to become dry, and the soil should be just kept moist. If potting is necessary, this should be done as soon as the young fronds begin to move, and as the growths start see that the plants are kept well up to the light. During growth the plants like abundance of water, but as the fronds begin to fade then gradually withdraw the water supply.]

Growing Guernsey Lilies (Nerines).—Would you kindly tell me the name of enclosed flower in your issue? There are six more like it on the umbrella, which is on a stalk about 18 inches high. I conclude it is the dark Agapanthus, but I cannot find mention of one of that colour, so should like to know. It is a bulb I got in South Africa more than 2 years ago, and this is the first time it has flowered. It is a lovely colour. I hope it will reach you in good condition. The leaves are only 2 inches or 3 inches long as yet, and do not seem to have any connection with the flower-stalk. It is in a 48 pot in the greenhouse. What should I do with it when the flower is over?—E. M. HAWLEY.

(*Nerine sarniensis* is the name of your plant. Its culture is very simple, and the production of the gorgeous flowers is certain, provided the following details be borne in mind.

often get ruined by being placed under a stage when not growing. By the above it will be seen that the Nerines have a dry season of some months. It is important to see the flower-spikes before watering, or the leaves will start to grow and the spikes will not appear. Potting should be done as seldom as possible. The Nerines when repotted are generally thrown one year out of bloom. They thrive for years in the same pot, piling one bulb on another, and thus greatly increasing the number of spikes to each plant. The best soil for them is turfy yellow loam without admixture of any kind; this, when the plants get well rooted into it, will last and keep them in good condition for years.]

CHRYSANTHEMUMS.

CHRYSANTHEMUMS OUTDOORS.

ALTHOUGH Chrysanthemums are imported in great numbers from the Continent and America, in addition to the many seedlings raised at home, we do not seem to make

more vigorous than in the middle of the plant. Pieces of roots make nice bushes the first year if a little fresh soil is placed about them. The ground must, previous to setting these pieces out, have been well dug and some rotten manure added. Care must be taken that the soil is not made too rich or the growth will not ripen. To induce a stocky, firm growth, make the soil when planting firm round the roots. When planting Chrysanthemums in the open avoid an aspect facing either north or west, and which is shaded by trees. The best position is a border facing south, with on the north and east sides shrubs or other protection. If the plants are well attended to during the summer a plentiful supply of blooms will be forthcoming, which, if the weather is at all unfavourable, will repay protection from early and sudden frosts.

The variety we figure to-day is, as a rule, in bloom in September, and is one of the best sorts for outdoor culture. The colour is a bright pink-lilac fading with age to almost white. It grows, as a rule, about 2 feet high. *Louis Lemaire*, a rosy-bronze sport from this, is a fine addition to the early varieties. There are now two white forms of the type, one called *White Grunerwald*, a seedling, and *Parisiana*, a sport much more vigorous than the parent. *Mrs. R. Mollinson* is a yellow sport, while in *Henri Yvon* we have a grand addition to the set, this being rosy-salmon on a yellow ground. T.

SEASONABLE NOTES.

THE display which the early-flowering kinds have made during the past three months is coming to a close, yet the freshness of the flowers may be preserved to some extent, if damaged and spent blossoms be removed and old and useless shoots cut out from the plants. This will give the collection a fresher appearance and also encourage the development of basal shoots, which peculiarity is most pronounced in the case of the best of the early sorts. Should open weather continue, many of the late October flowering varieties, which cannot very well be included among the early-flowering Chrysanthemums, will give an interesting and bright display. Such sorts as *Mme. La Comtesse Foucher de Cariel*, with its golden-orange flowers; *Godfrey's Pet*, the new bright yellow, free-flowering dwarf plant; *Harmony*, a splendid novelty, of a rich orange-apricot colour; and *Etoile de Feu*, an excellent crimson, of a rich and bright shade of colour, will do much to link the period when the earliest finish and the mid-season varieties begin their display. This type of plant is worth looking after, as they provide excellent material for indoor decoration in late October and early November. A few additional sorts of proved merit are *Bouquet de Feu*, bronzy-terra-cotta; *Vivid*, fiery-red; *Ettie Mitchell*, bronzy-yellow; *Gladys Roult*, pure white, very pretty; *James Salter*, pink; *Lady Selboune*, white; *Jules Mary*, crimson; *Mons. Willam Holmes*, crimson with golden reverse; *Ryecroft Glory*, golden-yellow; *Nellie Brown*, deep-bronze sport from the last-named; and *Soleil d'Octobre*, yellow. The mid season, or November-flowering kinds, which have been under glass for some weeks now, demand our attention at this season. Blooms intended for the November exhibitions are fast developing, and some of the earlier kinds are almost fully expanded. The question of feeding is still an all-important one, and care should be observed in its application. Some growers advocate feeding their plants until the blooms are finished, but this is not at all necessary. The use of manure-water after the blooms are about two-thirds developed predisposes them to dampness, which should be guarded against. Therefore withhold manures when the blooms are two-thirds expanded, doing this gradually. Green-fly is often troublesome, more particularly in glass-houses which are ill-ventilated. Do not wait for this pest to multiply to any great extent, but fumigate without delay. The only safe and reliable material with which to fumigate Chrysanthemums when in full bloom is the old and familiar Tobacco-paper. With this material the plants may be fumigated for twenty minutes or half-an-hour without the risk of damage to the blooms. If the blooms are left to finish without ridding the plants of

Chrysanthemum Mons. G. Grunerwald.

Nerines are cold greenhouse plants requiring a dry atmosphere all the year round. The treatment for one year (which should be repeated annually) is as follows: The Nerines begin to flower in the end of August and continue to bloom throughout the autumn. During flowering and afterwards throughout the winter and spring, the Nerines should be freely watered until the leaves by turning yellow show that the resting time has arrived. Throughout the remainder of the summer, while the plants are leafless, not one drop of water should be given until the flower-spikes appear, or in exceptional cases until the bulb, by its persisting in pushing up leaves at the flowering time, shows that it does not mean to bloom, in which case the plant must be watered and grown again until the next year. All the sun, light, and air possible should be given to them at all times. During the resting season a shelf in a sunny part of a greenhouse or cold-frame where air can be freely admitted without letting in the rain suits them admirably. These, like many other bulbs,

much headway in raising really hardy outdoor garden kinds that will live through the winter for some years and make their growth and develop a crop of bloom without any protection. At the present time a good selection of varieties that in reasonable seasons will produce a good crop of blooms can be had, much, of course, depending on the weather at the time they are at their best. Where there is a demand for cut-flowers some of the best kinds might be planted in quantity in the kitchen garden, choosing for them a warm border. In out-of-the-way gardens one often finds in bloom plants of sorts that are hardly ever met with nowadays. Many are Pompons, which, owing to their reflexed petals, throw off the wet and are thus well adapted for outdoor culture.

CULTURE.—Plants which have been growing in the same place for years get worn out. Such should be dug up and divided, discarding the centre of the roots if plenty of stock is available from the outer parts of the crown, where the sucker-like growths are always far

this pest, they will soon be quite unfit for use, either as exhibition blooms or cut flowers. Blooms showing evidence of damping should have the damaged petals removed by the aid of tweezers; they may be pulled out quite easily and the bloom saved. Japanese blooms with hard centres should have the offending centre released by the aid of specially designed forceps, which any Chrysanthemum specialist can supply. By the same means rough and irregularly formed florets should be pulled out, in this way insuring an even development of the bloom. In the case of incurved blooms, grown for exhibition, as far as possible dress these while they are on the plants. This will prove a great saving of time just previous to date of exhibition. In all cases where it is possible release the ties holding the shoots of the plants in an upright position, and allow the blooms to overhang in such a manner that the apex of each one points downwards. By these means deeper and more even and globular blooms may be obtained. Seared and decaying foliage should be picked off and burnt. When watering has to be done the morning should be chosen, and excessive moisture should be wiped from the floor subsequently. Look out for drip from the roof of the greenhouse, or some of the best blooms may be spoiled; prepare boards, cups, and tubes in readiness for the shows. E. G.

NOTES AND REPLIES.

Liquid-manure for Chrysanthemums.—I would warn growers against using liquid-manure too freely. Although it no doubt increases the size of the blooms, it decreases the quality of the cuttings, which come weak and flabby, and of little use where a healthy stock of plants is desired.—D. G. McIVER, *Bridge-of-Weir, N. B.*

October-flowering Chrysanthemums.—A mistake which is made too often with these (and I speak from experience) is too early propagation. I have met growers who invariably put their cuttings in as soon as they can be had, which is generally about November. This, I am certain, is neither desirable nor necessary to the successful culture of these plants. I have two batches of plants each of Mme. C. Desgrange and Geo. Wernig. The cuttings were inserted on January 29th of this year, half-a-dozen round the side of a 4-inch pot. These, when rooted, were potted singly, and shifted finally to the 6-inch and 7-inch size. These plants are now (October 15th) in full bloom, well clad with foliage right down to the pot, the height of the plants from the surface of the soil to the topmost blooms being 31 inches in the Desgrange and 4 inches less in the Wernig section respectively. That, I think, speaks well for late propagation, and the beauty is enhanced, as no sticks are necessary. The average number of developed blooms varied from 35 inches to 40 inches, and that on single plants. One can easily imagine the effect when three cuttings are grown on as one plant, using a 9-inch pot for the final shift. A new variety, Horace Martin, a sport from that well-known sort Crimson Marie Masse, promises to be a grand acquisition, blooming earlier than any of the Desgrange family.—D. G. McIVER, *N. B.*

ROOM AND WINDOW.

Barberry berries.—The richly-coloured berries of the common Barberry, borne in long, drooping clusters, have a very pretty effect when used for table decoration. Hardy kinds of flowers, fruit, and foliage undoubtedly get more popular year by year, and this is as it should be, as the pleasures of hardy subjects can be enjoyed by nearly everyone; whereas hothouse plants are for a limited few. To return to the common Barberry, the great profusion of its berries this season may be especially noticed, while I was recently much struck with a nursery bed of the smaller B. Thunbergi, which in a sunny spot was a mass of scarlet leaves and berries. This Barberry is certainly a very beautiful shrub, which, though now pretty and well known, is not half enough planted.—T.

The Prize Winners this week are: 1, Mrs. Heath, Dunley, Bovey Tracey, for *Laurus tinus*; 2, Mrs. Otter, West Grinstead, for *Horsham*, for *Dioscorea*.

ROSES.

ROSES OVER ARCH.

THERE are few more charming plants than climbing Roses for covering pillar, arch, or pergola. Many are the beautiful pictures afforded by these fragrant flowers, sometimes gurlanding a cottage porch, clambering over the roof and shrouding the very chimney in a shower of bloom, at other times thrusting long flower-studded sprays from among a mass of rampant climbers; or, again, as in our illustration, growing and flowering freely when loosely trained on a pergola. Given a deep and rich root-run these climbing Roses will succeed almost anywhere. Even in a north aspect, if the position is sheltered from cutting March winds, Roses will flower and often produce blooms of exquisite colour. W. A. Richardson in such a position frequently gives flowers far richer in tint than those borne on plants in the full sun. There are few more delightful pictures than *Rose d'Or* in the zenith of its beauty, while *Caroline Kuster*, *Mme. Berard*,

it retains its foliage quite as long as the so-called evergreen varieties. It is exceedingly vigorous, rambling quite as freely as the *Crimson Rambler*. The flowers, almost single, are of a rosy-crimson colour, but, as in most of these single varieties, the buds are long and handsome. If you want a yellow, you should plant *Aglaia*, a yellow Rambler.]

Rose Longworth Rambler as a bush.—In your issue of September 7, 1901, you were so good as to give me advice as to planting a Rose-bed. In the rows there are three plants of each variety. Would you now kindly tell me the proper treatment for the three plants of *Longworth Rambler*? They have made very long shoots—how long the plants seem somewhat out of place among the other bush Roses. Please also say how the *Gloire Lyonnaise* should be dealt with? They have grown vigorously. This bed (35 feet by 8 feet) was carpeted with one of the best sorts of *Tufted Fancies*, and has been a very pretty picture the whole summer.—R. V.

[In order to keep this *Rose d'Or* it should be cut back hard each year. Of course, it is best when afforded more space than you were able to give it, then the pruning would be of a more moderate nature. The *Gloire Lyonnaise* is really seen at its best when allowed to run as a pillar Rose, or trained against a low wall.

Rose *Blairii* No. 2 on a pergola. From a photograph by Mr. F. Mason Good.

but as you have this variety in the bed your growths may be cut back each year to about 15 inches of their base, and one or two of the oldest shoots cut quite down to the ground. Perhaps, to keep the bed of Roses uniform, you could plant the former variety as a pillar Rose in another part of the garden, introducing in its place the lovely variety *Mme. Jules Grolez* or *Corallina*.]

Roses for pillars and arches.—A complaint against the Rambler Roses is that their season of flowering is rather a short one. This cannot be denied, but they compensate for this by their lavish display. Much, however, may be done by the planter to relieve the pillars and arches of their forlorn appearance in autumn by planting a perpetual kind together with a summer one. It is true the growths would be very dense, but some must be sacrificed to accommodate the two kinds. Or an autumnal-blooming Rose could be planted on one side of the arch and the summer-bloomer on the other side. Personally, I should prefer the two planted together. For instance, *Crimson Rambler* and *Grass* an *Teplitz*, or *Felicite Perpetue* and *Mme. Alfred Carriere*, or *Aglaia* and *Mme. Berard*. If two contrasting varieties are preferred there is ample material at disposal. Recently I saw a pergola on which the Rambler Roses were freely planted, but on the columns autumnals, such as *Gloire des Rosomanes*, *Fabrier*, *Armand*, etc., were placed, and made a pretty effect.—Ros.

Blairii No. 2, Lamarque, Climbing *Devoniensis*, and the old, but still useful, *Gloire de Dijon* are well suited for such a position.

NOTES AND REPLIES.

Rose Mme. Victor Verdier.—This fine old crimson Rose has been remarkably good this autumn. A large bush just now is quite gay with the shapely blossoms, rich in colour and also fragrant. When we have a Rose that combines the good qualities named above with that of vigorous growth, its value is manifest. Doubtless the parent of several red Roses, I am not aware of any of its offspring superior to *Ella Gordon*. This is unquestionably of this parentage, although of even more vigorous growth.—Rusa.

Crimson Rose for pillar.—What crimson or yellow Rose would you recommend for growing up a 5-foot stake near the door, facing west, and enclosed by a wall? I do not want Turner's *Crimson Rambler*, as I have several of this a little lower down.—W. G. MURKIN.

[For a crimson you cannot do better than plant *Reine Olga de Wurtemberg*, which might almost be called an evergreen Rose, as

Request to readers of "Gardening."—Readers, both amateur and in the trade, will kindly remember that we are always very glad to see interesting specimens of plants or flowers to illustrate, if they will kindly send them to us in as good a state as possible.

FRUIT.

APPLE TOWER OF GLAMIS.

This variety is much grown in Scotland and the northern counties of England. In shape it is conical, the ridges being very prominent, as may be seen in the illustration. At first the skin is pale green, slightly flushed with dull red, the colour varying according to the soil in which it is grown. When stored it changes to a pleasing yellow. The flesh is firm and crisp, and when cooked has a sharp flavour. It can be kept well into February, and in a good fruit-room even later still. On account of its spreading habit the tree is not suited for growing as a pyramid, but might well be grown as a spreading bush if pruned sufficiently for the first two or three years to enable it to form a well-shaped tree. It does well as an orchard standard, the habit of growth not fitting it for the dwarfing stocks. The Crab is the ideal stock for it, and even when grown as a bush in the garden it is best to work it on this.

CANKERED PEAR-TREES.

(REPLY TO "BUDUNA.")

YOUR Pear-trees are suffering from a severe attack of canker, a disease which affects certain varieties far more than others. It nearly always arises from the fact that the roots go deep into a poor or sour subsoil, where they do not find the food or soil ingredients essential to the forming of sound, healthy wood. If you could open a trench 2 feet wide and deep round each of your diseased trees, 3 feet from the stems, you could make a clean severance of all roots found that are large, then you could work under the balls of roots and cut off as clean as possible with a broad, sharp chisel, fixed on a long Ash handle, all downward roots, refilling the trench with soil, you could check that tendency to canker at once. When the trenches are filled in remove the top soil about the trees, replace with fresh soil, and add a dressing of short manure, just lightly forking it in. The effect will be to cause the roots to make fresh growth near the surface, and those will produce sound, healthy wood. Before doing the root-pruning cut hard back all the cankered points of the branches, removing and burning them. You may benefit the trees also if, in the winter, but not when it is frosty, you make up a wash of fresh lime, soft-soap, and sulphur paste with water, and will syringe the trees with that, so as to coat all the branches; that will help to kill canker and insects. The mere cutting back of these decayed shoots each winter is of no use. The evil lies in the roots, and it is they which must be dealt with. It will do good also if, in the spring, 1 lb. per tree of bone-flour and Kainit be forked in over the roots. Do the root-pruning at once.

NOTES AND REPLIES.

Six good eating Apples.—I shall be greatly obliged if you will inform me in your valuable columns what are the best six (eating) Apples to plant in my garden, which has south-west exposure? Also whether I might safely plant these as late as middle of next month? —J. W. WALK.

[Try Lady Sudeley, Allington Pippin, King of the Pippins, Cox's Orange Pippin, Blenheim, and Ribston. If you want a very late kind try Stimmer Pippin.]

Brown scale on Peach-trees (F. G.).—Brushing and scrubbing the trees with strong insecticides are both laborious and only partially effective; whereas the petroleum remedy, if persevered with, effectually clears the trees of this troublesome pest. After the pruning is completed, the trees loosened somewhat, and the borders cleared of all rubbish, the wood-work and glass cleaned and the panes whitewashed, syringing the trees freely with petroleum, soft-soap, and water, and if this

soaks well into the border, good, rather than harm, will be done, especially if there was any black-fly on the trees. Heat the water to about 120 degs., this condition being insisted upon if the remedy is to have a fair trial, and to every 3 gallons of this add a lump of soft-soap about the size of a hen's egg and 5 oz. or three wineglassfuls of ordinary petroleum, or paraffin, as it is generally, but wrongly, termed. The oil must not be permitted to float on the surface of the receptacle, but should be kept mixed with the water, this being done either by returning every second syringeful (after the mixing has been accomplished by means of the syringe) forcibly back into the receptacle, or else by keeping two syringes at work, one distributing and the other keeping the oil mixed with the water. This mixture should be used in no half-hearted manner, it being of the greatest importance that every branch and shoot be thoroughly wetted by it. There is no necessity to syringe the trees

main rods and the ultimate fruiting canes at 3 feet apart down over the roof wire trellis towards the front, or at the bottom of the roof, and carry these growths upwards. The latter is nearly always adopted in ordinary cases of planting. This is known as the extension system, and very well it answers when the soil and house are suitable, and care is taken ultimately that the crop is not overdone. We have seen instances of Grapes growing much more satisfactorily on the extension than the single rod system, while the border lasts longer, because it is not so soon filled with roots, and less water is required for the same reason. The point of the growing Vine should be pinched when it is within about 6 inches of the roof wire; this will cause the issue of two leaders, which can be trained horizontally right and left. These in turn will give other shoots, from which, by selection, can be obtained growths that are to form the future bearing rods. Three feet apart for these is a very good distance.]

Fruit-trees for heavy land.—As I am about to plant an orchard in Cambridgeshire, I shall be glad if you will assist me in a selection of sorts most suitable to soil and situation? It is Grass land, with a heavy soil and a subsoil of gault. I have had holes dug 1 yard wide and 2 feet deep, and gault removed and replaced by lighter soil, which is now ready for planting. I shall be glad if you will name six dessert Apples, sixteen kitchen Apples, two dessert Plums, four kitchen Plums, and six Pears, all standards? G. BRAN.

[Several Apples of the greatest excellence might fail on very heavy land. Still, I know good Cox's Orange Pippin and Ribston are grown in Cambridgeshire, and in the present case I should plant one or two of each. Only in planting I should keep the roots well up, even to the extent of raising a mound a little above the surface. The following half-dozen should do well, if not planted too deep—Six dessert Apples: Cox's Orange Pippin, Allington Pippin, Lord Burghley, Beauty of Bath, Fearn's Pippin, and Ribston Pippin. Sixteen kitchen Apples: Lord Sutfield, Warner's King, Bismarck, Newtown Wonder, Stirling Castle, Lane's Prince Albert, Duchess of Oldenburg, Cellini Pippin, Pott's Seedling, Northern Greening, Bramley's Seedling, Blenheim Orange, Small's Admirable, New Hawthornden, and Alfriston. Two dessert Plums: Coe's Golden Drop and Transparent Gage. Four kitchen Plums: Early Rivers, Victoria, Prince Englebert, and Pond's Seedling. Six Pears: Williams' Bon Chrétien, Louise Bonne of Jersey, Beurre d'Ananlis, Doyenné du Comice, and Josephine de Malines.]

Bitter Peaches.—I should be glad if you will tell me how it is that some Peaches grown under glass, but scarcely "forced," have this year suddenly become very bitter, so much so that they remind one of taking a dose of quinine? They are ripe and well coloured, so it can hardly be the want of sun this season. Is this an uncommon experience? I should be glad of reasons, and means of preventing it another year. —MERRIS.

[In the absence of details regarding the nature of the soil in which your Peach-trees are growing, whether the base of the border is concreted, and the general treatment the trees receive in the way of watering and the use of either chemical or liquid-manures, it is somewhat difficult to account for your Peaches requiring the bitter flavour you complain of. It may be brought about by either of the following causes: (a) the application of too strong doses of either liquid or chemical manures; (b) through the roots having got out of hand and descended into and feeding on some deleterious substance in the subsoil. Of course, this is conjectural, but if you think the difficulty is caused through overclothing with manures, the remedy is obvious. On the other hand, if you think the roots are at fault, the trees should be lifted this autumn. The way to do this will be to open out a trench some 4 feet distant from the stem and about 2 feet 6 inches deep, making this wide enough, so that there will be room to work conveniently when throwing out the soil. From this trench, as a commencement, gradually work towards the stem by removing the soil from among the roots with a five-tined steel fork until there is a base of soil about 2 feet 6 inches in diameter, taking the stem as a centre. Then proceed to tunnel under the ball, doing one half first, and cut clean away all roots that tend to take a downward direction, doing this with a knife, and cutting them off close up to the ball. When this is done, fill up the opening under the ball either with the same soil, or with some fresh soil, and

Apple Tower of Glamis.

with clear water a few hours after using the petroleum mixture, and if one application of the latter does not thoroughly clear the trees of scale, a second dose should be given. If it does not also destroy thrips and red-spider as well as scale, mealy-bug, and aphides, it will, at all events, get rid of the greater part of them.

Planting Vine in small greenhouse.—I have a greenhouse, size 8 feet by 11 feet, height 3 feet 6 inches in front, and 7 feet at back. The greenhouse faces west, north end abutting on dwelling-house. The east wind is also well broken, so that it is in a very warm position. It is heated by a dry flue, 4-inch pipe, running along front, south to north. Am thinking of planting a Vine in same. Please say if house is suitable? In what position should the Vine be planted, and best kind to succeed? —MERRIS.

[The height of your house, both back and front, is not favourable for the growth and convenient treatment of Grapes. Still, there is no particular reason why you should not plant a Vine and that it may succeed. In such a house, with a suitable turf-made border, we should plant one Vine—the best for your purpose being Black Hamburgh—in the centre of the house, and in your case it would be better to either you planted at the back and trained the growths right and left to form

ram it very firmly as the filling is being done. Then do the other half in the same manner, and if properly carried out the ball will not be moved out of position in the least, and if this, as we strongly suspect is the case, is the cause of your trouble, the fruits should have their proper flavour another season.]

GARDEN PESTS AND FRIENDS.

THE FELTED BEECH COCCUS.

The scale insect known as the Felted Beech Coccus (*Cryptococcus fagi*), as a rule, chiefly attacks the trunks of Beech-trees, but sometimes ascends into the boughs. The females produce larvæ in September; these envelop themselves in a white cottony secretion and then cast off their antennæ and legs and remain for the rest of their life devoid of such appendages. The adult female is a small orange-yellow sac, surrounded by a white mass; these white masses often unite and form large felted patches, beneath which the larvæ burrow and develop. These scale insects suck out the sap very greedily, and often do much harm when present in large quantities. In time they cause the bark to peel off the tree, after which decay and death of the tree may ensue. It has recently been reported to the Board as damaging trees at Castle Eden, Durham. Large numbers of trees are attacked by this insect in Surrey, and it is also common in Cheshire, Huntingdonshire, and probably occurs in greater or less abundance wherever the Beech grows in Europe. Trees attacked by the insect should immediately be sprayed with strong paraffin emulsion twice, at an interval of two days. In the winter they should be sprayed with the caustic alkali wash. Scrubbing the trunks of the trees is too costly a method if the attack is severe, and thorough spraying with warm paraffin emulsion is quite effective. If the trees are cut down the bark should be burnt at once. It would appear that the Weeping Beech, of which two kinds are grafted on the common Beech, is not affected by this coccus. The stock may be attacked, but not the "weeping" scion. The insect does not appear to be attacked by birds, and very rarely by insect parasites.—*Journal of the Board of Agriculture.*

NOTES AND REPLIES.

Diseased Violets (*M. Tucker*).—Your Violets are attacked by the Violet smut fungus (*Urocystis violæ*), a not uncommon disease, but one that does not do much injury to the plants as a rule. If you cut one of the excrescences open you will find that there are a number of small, dark specks in rows. These will, as they ripen, come to the surface as a mass of soot-like spores, which fly about with the least wind and infect other plants. The best way of destroying this fungus is by cutting off and burning all the infested leaves and stems before the spores are ripe. Fungicides are of no use, as the fungus lives on the internal tissues of the plant, and so cannot be reached.—*G. S. S.*

Maggot in Pears.—I have two Pear-trees which blossom and show a heavy crop of fruit, which when about the size of, or a little larger than *Acorns*, drops off. I find at that stage there is a worm in the eye of the fruit. What I want to know is how to prevent this? The one tree is against an east wall, and the other in the garden in the open. Both are healthy and make a lot of wood. The one is near a Fir-tree.—*I. W. H.*

[Your Pears have been attacked by the grubs of the "Pear gnat midge" (*Diplacus pyrivora*). The fly is quite small, not measuring more than 1/4-inch across the wings. It is much like a small gnat in general appearance, though it belongs to quite a different family. It lays its eggs in the opening blossoms. The grubs are said to hatch in the course of four days, and immediately make their way to the core of the future fruit and begin to feed. Naturally the fruit so attacked never comes to perfection. When full-grown the grubs leave, the Pears falling to the ground if the fruit is still on the tree, or merely crawling out of them if they are on the ground. They then bury themselves an inch or so below the surface, and become chrysalides, from which the flies spring early the next spring. The trees should be well shaken so as to cause as many of the infested Pears to fall as possible, and the small trees

they may be gathered and burnt or buried deeply in the ground. A heavy dressing of Kainit (about 1/2 a ton per acre) applied under the trees in July or August has been found very efficient in destroying this pest. The removal of the surface soil to the depth of 2 inches would have the same effect, but the earth taken away must be buried deeply or burnt, so as to destroy the chrysalides.]

Ladybirds in greenhouse.—Can anyone tell me how to get rid of ladybirds in a newly-painted greenhouse? I have hundreds of them, and they are making their appearance in the house by way of the conservatory.—*H. G. W.*

[You can kill the ladybirds by burning sulphur in the house, but if the fumes are sufficiently strong to kill them, they will certainly injure the plants. The little beetles are searching for some sheltered place to pass the winter in, and will in all probability congregate together in some corner for that purpose. If they do they can easily be removed; but why interfere with them? They are perfectly harmless, and they and their grubs are of the greatest possible service in destroying aphides. I should never think of molesting them in any way, but always give them every encouragement. They will amply repay you next spring for any accommodation you may give them.—*G. S. S.*]

GARDEN WORK.

Conservatory.—Well-grown Cannas are very useful through the summer and autumn in providing us with a special feature both in flowers and foliage. They want plenty of pot-room and rich turfy soil to do them well, good drainage also must be given, as these large-leaved plants want plenty of moisture whilst growing and flowering. Good named sorts are cheap enough now, though seedlings from a good selection of kinds are worth growing. Some have bronzy foliage, and these are almost as effective as *Draenas*. Among the newer named sorts the following are good: America, reddish-purple; Duke of Marlborough, maroon, very dark-coloured flower; Edouard Andre, marbled salmon; John White, red flowers and variegated foliage; La France, bronzy-red; Roma, salmon-red, centre dashed with yellow; Africa, orange-red; Burbank, yellow, large flower; Italia, golden-bordered flower, very fine form; Rose Unique, rose, good flowers. When started in heat they will be in good form by midsummer, and will continue in condition till the autumn if given manure-water. These and other things of distinct appearance will relieve the sameness of the masses of *Chrysanthemums*, and though the latter are very bright and effective from a colour point of view, they are monotonous to all but the *Chrysanthemum* enthusiast. Of course, we appreciate these beautiful flowers, but the human mind wants variety. To do most things really well it is necessary to have several growing houses to get the plants near the flowering stage, and then move to the conservatory. The hard-wooded plants, for instance, will do in the conservatory whilst in bloom, but at other seasons they want special treatment to keep them in condition. *Cinerarias*, *Primulas*, and *Cyclamens* require special treatment during growth, but they make lovely little groups when in flower, especially when mixed with Ferns or graceful fine-foliaged plants. Above all things do not crowd anything, and make a free use of fine-foliaged plants. Baskets suspended should be as bright and effective as possible now. Among suitable plants are the *Epiphyllums*, which will soon be in flower. Pink *Begonias*, with the sides of the baskets draped with light coloured fine leaved plants, are charming. *Sedum carneum variegatum* is a good plant for covering sides and bottom of baskets, and as the plant is quite hardy it will thrive in a cold house, but it does well in a heated structure also. The variegated form of *Ficus radicans* is a desirable thing to have in quantity, as it may be used in several ways.

Forcing-house.—We are not forcing much yet, but preparations are being made to start a few *Roses*, bulbs, and other things. Every experienced forcer is aware of the fact that though a genial temperature will do a good deal, it will not bring blooms out of a bulb or other plant if the flowers are not ready there,

waiting for the warmth and moisture to bring them forth. The principal part of the flower and fruit-forcer's work is done the previous summer. In starting pot-Vines it is customary to start at a low temperature and gradually work upwards. In a general way this is doubtless right, but I have generally found the result is far better if a longer rest is given and the start made a little more briskly. Especially is this the case with pot-Vines, Figs, etc., and it helps those who have only one forcing-house and desire to grow a number of things there. For instance, one may have started a few French Beans and a few plants of Cucumbers or Tomatoes, and they may be coming into bearing in November, and, when the time comes to introduce the pot-Vines, they generally have to put up with the temperature which suits the things already started. If the Vine-rods have been well ripened and rested, they will start very well in a temperature of 55 degs. to 60 degs. The great point is getting the eyes to break, and this is done by keeping the canes in a horizontal position on the bed of leaves and frequently damped. If any canes are slow in breaking, twisting them round a few times liberates the sap and sets it in motion at once. Asparagus, if the roots are strong, can be forced in a warm-house, placed close together in boxes or flat baskets, and kept moist.

Late Peach-house.—This has not been an ideal season for ripening wood in cold-houses, and if the wood appears green and unripe a little fire-heat will be useful. We know fuel is dear, and, judging from the less condition of the miners, is not likely to be any cheaper. Still, fire must be used, if necessary, to obtain the desired result. Free ventilation will do something, but it is the circulation of warm air that is wanted to ripen the wood of fruit-trees.

Bottling Grapes.—When vicieries are required for wintering bedding and other plants which require watering from time to time, if only a few bunches of Hamburg or other thin-skinned Grapes are left hanging in early or mid-season houses, it will be better to cut the Grapes and bottle them in the usual way, and keep them in a dry room with a steady temperature of 50 degs. or so. Late houses will, of course, be left as they are for the present, keeping the atmosphere dry and the house reasonably ventilated, with a little warmth in the pipes to keep the air in motion. No Vine-leaf should be permitted to touch the glass from this onwards to cause drip in the house. Where possible, inside Vine borders should be covered with clean litter to keep down dust and check evaporation. There will then be less moisture to condense on the glass and drip about the house, and, consequently, there will be less decay among the berries. Outside borders should be covered with a good thickness of tree-leaves, and over the leaves shutters should be placed to throw off heavy rains.

Cold-frames.—These will now be filled with various crops coming on slowly, Violets for potting, Strawberries for forcing, Cauliflowers with hearts in course of formation, or young plants just pricked out from the autumn sowings to come on for the early spring and summer crops. Bulbs intended for forcing and other plants waiting for the forcing-house will also find shelter here for a time. Auriculas, Carnations, and other plants which only require a small amount of shelter will find a home in a frame.

Hotbed making.—With plenty of leaves and stable-manure the making of hotbeds is an easy and simple matter. There is not much forcing going on just yet, but beds for forcing Asparagus and Seakale may be made up. The proportion of leaves and stable-manure should be one half of each, and the blending should be as perfect as possible, and then the heat will be steady and serviceable. The beds at this season should be about 4 feet high, and be pretty firmly built.

Window gardening.—One of the brightest and best plants at this season is the Scarborough Lily. It is not difficult to manage, and like a good many window-plants it enjoys a season out-of-doors to mature growth. It may be turned out early in July and brought back when the flower-spikes are visible

in September. The Norfolk Island Pine (*Araucaria excelsa*) is a very useful room plant that is getting common now. Palms of various kinds never were so much in evidence as now. Kentias are the most useful, but the plant for the town house is the *Aspidistra*. Treat it naturally and it is indestructible.

Outdoor garden.—Roses may be planted now if the beds are ready. The soil should be well broken up, and if possible have a little good loam placed round the roots when planting. A little lime and soot worked into the land at the last turn over has a beneficial effect. It sweetens and cleanses the land, and all plants make clean, healthy growth after its application. If planted early in November, the plants will begin to make roots immediately. If the plants have made much growth, the largest shoots should be shortened a foot or so to relieve the wind pressure. The roots also may be shortened a little to encourage the production of fibre. It benefits bush Roses to replant occasionally in fresh well-worked soil, especially where mildew has been prevalent. Transplanting gives the plant a new lease of life, and this, of course, will be followed by harder pruning than usual. This is a good season to renew and replant herbaceous borders. This treatment is necessary every three or four years, and this gives an opportunity for rearranging the plants and adding anything new. Where there is a number of borders to plant each might be treated differently; as regards planting, the grouping system gives the best general effect. But collections of individual plants are exceedingly interesting to the plant-grower who loves his flowers apart from the effect created. Give prompt attention to bulb planting in beds and borders.

Fruit garden.—The early vinery and first Peach-house should be got ready for work now. There is not so much early Grape forcing done now as was necessary before the thick-skinned Grapes became so common, and the first lot of early Grapes is very often grown in pots, and as a fresh lot of Vines is grown every year for forcing, the second house need not be started before January. When the canes are well ripened, Vines in pots force very easily, and if well nourished during growth very good fruit can be grown in pots. A low span-roofed house is the most suitable, and if the pots can be plunged in a bed of leaves on each side the house, very good results are obtained, though I once had a lean-to house which did not Vines very well. There was a broad shelf along the back, and one set of Vines was plunged in the narrow front pit, filled with leaves, and the Vines on the top shelf were trained down. Both sets did equally well, though the berries on the plunged plants were always the larger, as the roots worked out of the pots into the leaf-bed. This is the time to plant Raspberries. There is no lack of good varieties now. For dessert plant Superlative. Beehive and Norwich Wonder are also good. Do the land well, as though Raspberries are surface rooting, the roots will run down for their food if the land has been well prepared. Autumn Raspberries are bearing well, and the fruit comes in very useful for tarts with late Red Currants. These latter are good on north walls. We have had them up till the end of November.

Vegetable garden.—The earliest-planted Brussels Sprouts will now be coming in, and, as Peas will soon be over, the Sprouts will be useful. Spinach, also, and Cauliflowers are plentiful and good. Scarlet Runners and French Beans are at the time of writing untouched by frost in our immediate neighbourhood, but this state of things cannot last long. French Beans coming on in pits will prolong the season, and a crop of dwarf Beans under a south wall can easily be sheltered when frost is expected. But the time is close at hand when all tender things exposed will be spoiled by frost, and provision for a supply from other sources must be made. The supply of salading requires some forethought and some means of affording shelter, as Lettuces, when of considerable size or when turning in, will soon decay after being frozen through. I have before referred to the easy way in which Lettuces which are full grown can be kept in condition a long time by a covering of dry leaves, and just a little long fresh litter on top

to keep the leaves in position. The Lettuces should be tied up when dry. There are other ways of protecting and blanching Endive. It keeps very well when covered with mounds of dry ashes after being tied up, and the Endive blanches quickly when lifted and placed in the Mushroom-house a few at a time when required. Of course, there will be Lettuces and Endive coming on now in frames, and it will be an advantage if a heated pit is planted with Lettuces to come in for an emergency in case of bad weather. In my experience these emergency crops always come in very useful. Put a few roots of Chicory to force in the Mushroom-house. Have a few roots of Tarragon and Chicory to supply green pickings when required. E. HORDAY.

THE COMING WEEK'S WORK.

Extracts from a Garden Diary.

November 3rd.—Finished preparing the ground for a plantation of Apples on the English Paradise. They will be planted 10 feet apart each way in blocks of twenty or more trees of each kind. The sorts will include Cox's Orange Pippin, Newton Wonder, Bismarck, Allington Pippin, Worcester Pearmain, Stirling Castle, Lano's Prince Albert, Peasgood's Nonsuch, Bramley's Seedling, and Barnack Beauty. Moved a lot of forcing shrubs to cold-house. These, for the most part are established in pots, and have been plunged out, and include Deutzias, Rhododendrons, Prunus triloba, etc.

November 4th.—Evergreens are moving well now the ground is moist. There is always some of this work to do to keep things moving on comfortably, especially where new things are introduced from time to time. A bed has also just been prepared for Tree Paeonies. The site is sheltered, and peat, leaf-mould, old rotten turf, and sand have been freely used. These are lovely things, and we are anxious to see them thrive. Repaired turf on tennis-lawn. Box edgings are also being put in order. In some cases the Box is taken up and replanted, and afterwards the gravel is turned over and rolled down firm.

November 5th.—Mustard and Cress are sown in boxes twice a week in heat. We have still two houses of Tomatoes well set with fruit that will give us ripe fruit till after Christmas. Things move more slowly now, and we have no desire to hurry them beyond getting a steady, regular supply. Planted more Cabbages and Brown Cos Lettuces on warm borders. Full-grown Lettuces and Endives are being protected in several ways—some are coming on in pits and frames, others which are full-grown are surrounded by dry leaves.

November 6th.—We have just finished planting late Tulips and Hyacinths in beds and borders. These usually make a very fine display in May, better and more lasting than the earlier kinds. Many Tulips have been planted thickly in rather shallow boxes and covered at present with long litter. One has only to lift up the litter to see that progress is being made, and by-and-by the boxes will be placed under glass, and later introduced to heat. They will come on under the stage in a warm house. This growth in a subdued light gives length of stem.

November 7th.—There is always work to be done among the herbaceous plants in the borders. Having a number of borders chiefly occupied with hardy plants, there are generally a few borders that want replanting with a view to re-arrangement every season. Most of the plants are lifted, the ground manured and trenched, and when time has been given for settlement the plants are placed in position, not often in the same way, but mistakes in planting are corrected and a better general effect is as far as possible secured. Top-dressed Cucumbers in bearing with warm soil. All water is now used at the same temperature as the house.

November 8th.—Re-arranged conservatory with a view to make the most of the Chrysanthemums. In addition there are groups of other things which act as foils to the great show of flowers. Very bright are the scarlet *Salvias* and Scarborough Lilies, and a small group of retarded *Lilium longiflorum* is blooming. Moved a lot of Roman Hyacinths

into gentle heat to open the flowers and give length to the spikes. A few plants of *Azaleas* have been moved into a house where a little more warmth may be secured. We shall want them at Christmas. *Arum Lilies* also are moving on.

UNITED HORTICULTURAL BENEFIT AND PROVIDENT SOCIETY.

THE annual dinner of this society was held at the Holborn Restaurant on the 16th October, A. W. Sutton, Esq., F.L.S., of Reading, in the chair. We are pleased to see that this society is going forward by leaps and bounds, there being now 974 benefit members, the invested money being £20,000. We hope that the wish of the Committee may this year be fulfilled—viz., to have 1,000 members. We do not think any society worked on similar lines could show an investment of £20 per member. During illness, a member on the higher scale receives 18s. per week for six months, and half that sum for the remaining six months, while members on the lower scale receive 12s., and 6s. per week for the same periods. A yearly balance sheet is issued to each member, so that at the end of the financial year each knows exactly what stands to his credit, and in the event of death his nominee is paid that sum, while at the age of 70 he may, if he chooses, withdraw his balance in a lump sum, or draw on it as he thinks fit. Lapsed members at the age of 60 can obtain the balance standing to their credit when they became lapsed members. The Benevolent Fund is provided by the contributions of Life and Honorary members, and also a small annual sum paid by each Benefit member. Members having passed the age of 70 can participate in this fund, while any member in distressed circumstances, or widows of members who die in needy circumstances, are assisted from it. The Convalescent Fund, which we should like to see taken more advantage of, was started to assist members who after an illness are desirous of having a change of air. The Management Fund deals with the working expenses of the society. Towards this each member contributes annually 2s. 6d., the balance, when necessary, being made up from the interest of monies standing to the credit of lapsed members, and the proceeds from advertisements in the annual report. The secretary, Mr. W. Collins, 9, Martindale-road, Balham, will be pleased to answer any inquiries about the society.

LAW AND CUSTOM.

Cattle breaking through garden fence.—A hedge, which belongs to me, and which is a very bad one, divides my garden from a field occupied by a farmer. His cattle broke through my hedge and destroyed some 300 cabbages. When I asked the farmer to make me compensation, he told me I should keep my hedge in proper repair. Can I claim damages through the county court?—J. W.

[You can recover damages through the county court if you are under no obligation to maintain a fence against the stock in this field. It will be for the farmer to prove that you are under such an obligation. When a piece of land is sold off from a field for building purposes the purchaser usually covenants to maintain a fence between the piece purchased and the rest of the field. If your garden originally formed part of this field, the purchaser probably entered into such a covenant, and, if so, you cannot recover compensation.—K. C. T.]

BIRDS.

Parrot ailing (No Name).—This bird is suffering from a severe attack of indigestion, due, no doubt, to improper feeding; but no particulars are furnished as to general diet and mode of treatment. The only thing mentioned is white bread, which is certainly improper food. Very often this trouble is the result of absence of small stones in the gizzard, where they are necessary to enable that organ to properly triturate its contents. There should always be a supply of coarse sand in the cage, from which the bird may select enough small stones to keep its digestive organs in working order. The grit should be put in a food-tin and placed inside the cage. A theriac vomiting, or a solution of drinking water must be given, and a teaspoonful of liquid magnesia

to each ounce of water supplied three or four times a day. Feed on Maize (which should be boiled till soft, and then wiped dry). Canary-seed, Hemp, Millet, Oats, with occasionally a few Nuts and pieces of Apple. Never give animal food in any form. Keep the bird warm, maintaining a comfortable temperature around it night and day. This appears to be a bad case, and great care must be taken of the bird if its life is to be saved.—S. S. G.

CORRESPONDENCE.

Questions.—Queries and answers are inserted in *GARDENING* free of charge if correspondents follow these rules: All communications should be clearly and concisely written on one side of the paper only, and addressed to the EDITOR OF *GARDENING*, 17, Finsbury-street, Holborn, London, E.C. Letters on business should be sent to the PUBLISHER. The name and address of the sender are required in addition to any designation he may desire to be used in the paper. When more than one query is sent, each should be on a separate piece of paper, and not more than three queries should be sent at a time. Correspondents should bear in mind that, as *GARDENING* has to be sent to press some time in advance of date, queries cannot always be replied to in the issue immediately following the receipt of their communication. We do not reply to queries by post.

Naming fruit.—Readers who desire our help in naming fruit should bear in mind that several specimens in different stages of colour and size of the same kind greatly assist in its determination. We have received from several correspondents single specimens of fruit for naming, these in many cases being warped and otherwise poor. The difference between varieties of fruits are, in many cases, so trifling that it is necessary that three specimens of each kind should be sent. We can undertake to name only four varieties at a time, and these only when the above directions are observed.

PLANTS AND FLOWERS.

Pot roots of Dahlias (R. H. Sneyd).—When the root has killed the tops, cut them off and stand the pots containing the tubers in the greenhouse, under the stage, till next March, when start them into growth in heat and put on, finally planting out at the end of May.

Greek Valerian (Polemonium) (M. Watson).—A small family of hardy herbaceous perennials, mostly from America. They are easily increased by division of the roots, and any garden soil will do them well. The best known is Jacob's Ladder (*Polemonium coeruleum*), which bears erect stems, 1½ feet in 3 feet high, and a showy terminal corymb or panicle of flowers.

Pressing Tuberous Begonias (Gladstone).—Lift the tubers in the autumn, and lay the tubers on a shelf in the dry for a couple of weeks or so, and when the growth falls away from them store them in a box in dry sand. You must keep them in a frost-proof place. Next March they may be potted singly into small pots, and planted out again about the end of May.

Marking a tennis lawn (Green).—The court should be 75 feet long and 27 feet wide for a single-handed game, and for a double-handed game, 78 feet long and 30 feet wide. It is divided across the middle of the length by a net, which is 3 feet 6 inches high at the posts, and about 3 feet in the middle. The service lines are 21 feet from the net and parallel with it.

Planting the English Iris (Constant Reader).—This bulbous iris is not a native plant, but comes from the Pyrenees. In cottage gardens it flowers annually in light soil, and in a sunny situation. You ought to plant at once, although we have been successful with it planted even so late as November. The English Iris flowers later than the Spanish and German Irises, and is at its best about the end of June and the early part of July.

Iris stylosa (Wadwin).—The correct answer depends on the size of the plants, which we imagine are not large. If this is so, let them alone by all means. In any case, if you wish to divide the plants, do not do it now—March is a far better month; indeed, we regard March and April as about the best time of the whole year. Loam, leaf-mould, peat, and old mortar in almost equal parts will suit quite well, and if the root-fibres are in a restricted area and against a wall, so much the better.

Ranunculus (J. Smith).—You ought to have allowed your Ranunculus to die down, and stored the tubers away until planting time came round. The only thing you can do is to leave them as they are, and when the foliage lies down to lift and store them. Some people plant in October, but, unless the soil and situation are favourable, you had better defer this until February, when select a rather warm, sunny place, if possible. The bed should be of good material, and, if the soil is heavy, plenty of sand should be added to assist a free drainage.

Rabbits in the garden (N. E.).—A good plan, which one of our readers found efficacious, was to put rat-traps tied to little stakes round the bed in which Carnations, etc., were growing. Rabbits object to the smell of tar, and tarred string can be had very cheaply. Failing this, the only thing you can do is to surround your garden with wire netting, burying one side about 1 inch in the soil, as, if this is not done, the rabbits will scratch under it and find their way through. In the case of the field rats, the only way is to trap or shoot them.

Iceland Poppies (W. Thompson).—The seedlings have been either cleared off by one of the many voracious caterpillars, or are drawn in by worms. We know of no instance, however, where all vanish in this way, and would suggest in future your experimenting with soot and lime mixed with the soil below the seedlings, and also a further patch dusted over the surface with soot. A capital plan, when only a few clumps are required, is to sow, say, half-a-dozen seeds in a 6-inch pot. Two dozen such pots may easily be dealt with, and if stood on a hard bottom-boards, some sowings or the like—worms are kept at bay. An additional advantage of this treatment is the non-crowding of the plants, and their ultimate development and better flowering more than you could expect.

dealing with the pots. In a few weeks the seedlings are strong enough for planting out bodily without disturbance of any kind.

Gladstone The Bride (M. Watson).—Those who have to keep up a supply of cut flowers should grow a quantity of this, as it is not only very useful for conservatory decoration, but will stand much forcing. In a light, sandy soil the bulbs may be left in the ground all the winter, covering up the young growth with litter, as, coming up early, it is liable to be injured by frost. These bulbs, left in the ground, will flower earlier than those that are lifted and stored. By planting at intervals from now up to Christmas you can prolong the flowering season of this useful plant.

Lilacs (H. L. F. H.).—You may certainly plant the Lilacs in the borders with every hope of success; indeed, there is no reason why the majority should not show a decided improvement. Deal with them at once. Take out a good hole for each potful, dig the soil deeply, say, 15 inches or 18 inches, work in some old manure low down, and some sharp sand if the soil is heavy. Then knock the plant out of its pot, and, after removing the drainage, plant bodily in the hole in such a way that the old ball will be covered to a depth of 3 inches. If you have any good soil, it will be an advantage to put some around the ball before filling in the ordinary soil. For *L. auratum*, no manure, or only very little, need be used, but a good dressing of sand is helpful. Select for this kind a place, if possible, where some shade will be given. If you can plant it among peat-torcing shrubs, or the like, so much the better.

Daisies in lawn (H. C.).—Where there are lawns in a lawn, mowing should be done every few days to destroy the flowers, and thus prevent their seedling. Your efforts must be directed to the pulling out of the Daisies, and taking care that any that may be left are prevented from flowering next summer. You may also help the grass to extend by now dressing your lawn with basic slag, 4 lb. to the rod, or making it into the roots with a rake. A dressing of sulphate of ammonia applied next April will be very beneficial. There is a lawn said to kill Daisies, but it only burns the leaves, and does not kill the roots. You can relay turf now; in fact, this can be done at any time now, when the weather is open and mild. Certainly you can dig up the lawn now and let it settle during the winter, breaking up the surface and making firm, then sowing Grass-seed (not that from a hay-loft) in April.

Fragrant Roses for greenhouse wall (Demetri).—Of the names you mention, *Boschica* would be the best for your low wall. It is a fine Rose in every way, and fragrant. Adam would be another good kind, and for a rich crimson, you could not do better than *Plant Liberty*. The other kinds named would not be at all suitable for this wall. If you desire greater variety, there are *teatote* Inconstance, which gives a lovely bud, *Mme. Abel Chatenay*, one of the sweetest and best of Roses, *Mme. Guerin*, somewhat dull in colour, but fragrant, and also its two sports, *Mrs. Pierpont Morgan* or *Mrs. Oliver Ames*. Another charming Rose is *Grand Duchesse Anastasia*, and the same may be said of *Souvenir de G. Herve*, *Victor Succed*, *good old pink*, *La France* and *Caroline Testout* should succeed well in the position. Two very fragrant old Roses now rarely met with are *Mme. de St. Joseph* and *Goulstair*, and both are very good growers, well fitted for such a wall.

FRUIT.

Pruning Red Currants (Red Currant).—Red and White Currants are liable to be stripped of their buds by birds, and, if such is the case in your garden, you had better defer pruning until January. Red and White Currants, grown as bushes on a short stem, should have the centre kept quite open, the main branch being about one foot apart. In order that the branches may be well furnished with fruiting spurs, the leading shoot on each should be shortened to about one-third its length, and, if there is room for another branch, reserve a well-placed shoot, which shorten to about one-third its length, and gradually build up a strong bush. All side shoots should be spurred back to about half-an-inch of the old wood, the fruit being generally borne in clusters round these spurs. Your wall trees should be pruned on similar lines.

Pear-trees not fruiting (Dunlop).—We have seen Jargonelle and Marie Louise Pear-trees that on a wall, just as yours are, have not fruited, although flowering regularly. Such have been induced to fruit freely by allowing strong shoots to break up from the upper horizontal branches at intervals of 18 inches apart, all shoots below being hard pinched or pruned back to three or four leaf buds early in August. These top, erect shoots, the first winter, have been cut back to one-third their length, and allowed the following year to carry one strong leading shoot only, that course of treatment being repeated the following years. Then these growths have carried the crops of fruit. They soon become stout, and need no supports. It brought on archer in the front they can be tied to stout sticks fixed to the trees, and thus form Pear arbours. The only other remedy is to severly prune the roots, a difficult job, and to hard prune all the shoots at the same time.

Plums not fruiting (Scott).—We can readily understand that a Green Gage Plum will not set bloom in your very high, cold northern elevation, but, if you plant, though on a wall, the tree needs to be covered with glass; but, as the variety does badly, and you would, perhaps, prefer a Plum, the best for your purpose would be a flat-framed Victoria. If you prefer an Apple, then plant *Lord Grosvenor*. With respect to your Victoria Plum-tree—probably a standard—you would do well to shorten the previous season's shoots, in the winter, to one-half their length, as the points do not ripen well. But should the branches, in consequence, throw out young shoots further back, those must lie, in August, cut back to three leaves to induce them to form fruiting spurs or buds. Under no circumstances should leaves be picked off, but shortening back these young back or side shoots will give the fruits ample light and air.

VEGETABLES.

Fungus in Potatoes (J. Mayne).—The Potatoes are attacked by a fungus, which is not in a condition in which it is possible to say to what kind it belongs. Still, if it may grow, and I may be able to tell you something

more about it if it does. It is often impossible to recognize fungi unless they are in what would be in flowering plants.—In fruit.

Green Tomato Cuts (Mrs. Willoughby L. Cotton).—Put a pint of vinegar in a boiling-pan with 1 lb. of Demerara sugar, and let this boil until the sugar is dissolved. Slice six or seven Tomatoes into thin slices, and use, with the same weight of Apples, peeled, core and cut into quarters, 1 oz. of bruised Ginger, six red and 1 lb. Shallots, 1 lb. Sultanas, allowing 1 lb. of Sugar and these spices for each pound of Apples and Tomatoes; salt to taste. Boil these well together, stirring all the time, until it is thick, like jam, and set firm when a little is dropped on to a plate. Pour into hot glass jars. Cover when cold, and store in a cool, dry place.

SHORT REPLIES.

P. B. S.—Your plant is *Cryptomeria elegans*. It will far better planted out in the open.—*Edwin*.—No, if you can make a border and plant the Vines into it, it will be far better in every way. We shall be pleased to help you if you decide to do so.—*Coz*, *Gladstone*.—You are entitled to all force, or, if you have plenty of litter, force where the crowns are. You will find in back numbers many articles dealing with the propagation of Seakale.—*G*.—We would find no insects in the box, with the exception of some small earth-worms, which will do no harm.—*A Constant Reader*.—The only thing we can suggest is that you keep the house too moist. Have you any fire ball?—*E. M. O.*—Box to hand, but there was no insect.—*G. W.*—No enclosure. Letter was found open by *Ed. W. William Foster*.—You ought to get the "Key List of Trees and Shrubs," in which the latest nomenclature is given. *The Garden* is now published at 23, Tavistock street, London, W.C.—*Urbidie*.—Yes, the sooner they are planted the better now, as they will be established before the severe weather is on us.—*Mrs. L. W. Taylor*.—You will find an article dealing with "Water Gardening" in our issue of Aug. 9, 1901, p. 201. This can be had at the publisher's post free, for 1s. 6d.—*P. W. B. A.*.—The best plan will be to consult a local gardener, who can see the ground of which you speak.—*Emmeline*.—It would be up too much of our space to answer your question fully. The best thing you can do will be to purchase some of "Vines and Vase Culture," price 5s. 6d., post free, from A. E. Barron, 11, Sutton-court-road, Chiswick, London, W.—*J. S.*—Your query is very indefinite. You ought to have favored your Carnations in August, and the boys would now be ready to go into fresh quarters to those next year.—*W. O. Minter*.—A very suitable plan for such a position would be a tetra-tropie or an ivy-leaved Geranium. You will find the latter by *Bella* advertised in our pages.—*M. A. Tower*.—Your various queries were answered fully in the article to which you refer. Any nurserymen could get you the bulbs. See our recent queries.—*Russ*.—See reply to "Aun," in "Dear reader." In our issue of Oct. 11.—*Sandy*.—The only way you can do is to trench the ground to get rid of the soil, in the same time adding a good quantity of heavy manure to the work processes, as also the cow-manure which you have.—*W. Chalmer*.—Not a gardening question.—*Teatote*.—1. You will find an article dealing with the potting of bulbs in this week's issue, p. 464. 2. You will sow the seed at once, as in this way it will germinate far better than if put away. 3. You will find an article with illustrations of Tritomas in our issue of Oct. 4, p. 4. You cannot do better than plant *T. Uria*.—*Constant Reader*.—Not a gardening question. You ought to consult a solicitor.—*Constant Reader*.—Kindly see what Statice you refer to.—*W. O. Minter*.—Yes, the *Crataegus Pyracantha* would answer very well in such a position.

NAMES OF PLANTS AND FRUITS.

Names of plants.—W. Teubert.—We cannot undertake to name florists' flowers.—*L. B. Robinson*.—1. Spindle-tree (*Eunonymus europaeus*); 2. *Cotoneaster frigidus*;—*W. J. T.*—Common Mellot (*Melilotus officinalis*);—*D. C. R.*—1, 2, 3. Forms of Aster Novi-Belgii; *Aster cordifolius* elegans; 5. Aster Novi-Belgii Robert Parker; 6. Aster diffusus horizontalis;—*P. J. C.*—1. *manibus pubescens*.—No name.—1. *Chrysanthemum maximum*; 2. *Pyrethrum uliginosum*; 3 and 4. *Aster Novi-Belgii* vars.; 4. *Aster Novi-Belgii* semi-plena; 5. *Aster Novi-Belgii* W. Bowman;—*T. N.*—*Polygonum sp.*—*Miss G. H. Kingston*.—1. *Aster cordifolius*; 2. *Helianthus rigidus* Miss Mellett; 3. *Aster cordifolius*;—*C. A. W. Catrill*.—Bougainvillea glabra;—*B. J.*—1 and 3. *Adiantum cuneatum*; 2. *Selaginella Martiana*; 4. *Adiantum cuneatum* grandiceps. It is unfair to send me small scraps.—*J. Giffie*.—1. *Cryptomeria japonica*. Please send a coming branch; 3. *Larix* sp.; 4. *Betula* sp.—*W. R.*—*Berberis Aquifolium*.—*St. John's Wort*.—*Modern Rugeriana*.—*M. C. H. B.*—*Nelusa ampullifolia*.—*G. H.*—1. *Baphoelepis indica*; 2. *Phibedactrum*; 3. *Selaginella Kraussiana*; 4. *Selaginella cuneata*; 5. *Polystichum angulare*.—*H. M.*—Rose falls to pieces.

Names of fruits.—Mrs. Tidwell.—1. Apple;—*Scott*.—2. Pear Fondante d'Autonne.—*S. C.*—1. King of the Pippins; 2 and 4. Cox's Orange Pippin; 3. Pears Pippin.—*Sunset*.—Quite impossible to name the berries on receipt being quite smashed up owing to bad packing.—*A. A. Lucas*.—Specimens insufficient.—*Mrs. Campbell*.—1. Apple Ecklinville Seedling; 2. Probable old head.—*G. Gutsell*.—Pear Beurre Hardy.—*Mary P. Merris*.—Quite impossible to name from such specimens. See reply to "Aun," in our issue of Oct. 11, p. 4. 1. Pears cracking;—*Ross*.—Pear Beurre Capaigne; 2. October and early November Pear.—*Alice*.—1. Yorkshire Greening; 2. Pear not recognized.—*E. Coz*.—Pears: 1. Small, Fondante d'Autonne; 2. Large Duchesse d'Angoulême; 3. Apple; 4. Scarlet Nonpareil; 5. Biscuit; 6. Biscuit; 7. Biscuit; 8. King of the Pippins; 9. Cox's Orange Pippin; 10. King of the Pippins; 11. *M. M. Merris*; 12. *Verdun*;—1. *Selwood Reinette*; 2. Queen Caroline; 3. Bismarck; 4. Duchesse of Oldenburg; a very late fruit.

Catalogues received.—Pennick and Co., Delant Nurseries, Wicklow.—*List of Shrubs and Forest Trees*—Blackmore and Langdon, Tiverton Hill Nursery, Bath.—*List of Carnations, Potatoes, etc.*—*Jas. Backhouse and Sons, York*.—*List of Roses, and List of Conifers*.—*P. C. Heinemann, Erfurt*.—*List of Sweeties for 1902*.

PLANTS AND FLOWERS.

INDOOR PLANTS.

BOUVARDIAS.

In the greenhouse the different varieties are valuable, and where there is a demand for the choicer class of flowers for button-holes, wreaths, and similar purposes, Bouvardias are extremely useful. Blooms of them are had to a limited extent almost throughout the year, but their regular season of flowering is in the autumn and winter, when, indeed, they are more appreciated than at other time. For winter flowering the plants are usually struck early in the spring, cut off as soon as rooted, and grown on during the summer months. Different methods followed by cultivators, for by some the plants are kept altogether in pots, and by others they are planted out in a frame (under which conditions they will grow with great freedom) and carefully lifted and potted in the autumn. In this last is carried out, the plants should be kept close and shaded from very bright sunshine till they have recovered from check of removal. The nurserymen that sell Bouvardias in large quantities, as a rule, keep them altogether in pots, for neat flowering specimens may be had in pots 5 inches in diameter; whereas, if planted out they would give so great a check to get them into pots of that size that the plants would suffer greatly, and large pots are, as a rule, not appreciated buyers. Large specimens for conservatory decoration where pot-room is no object can be grown well on the planting-out system, and so those needed for the supply of cut blooms. In this last purpose if the old plants are in spring, when all danger from frosts is past, planted out in a warm prepared border, they can in an ordinary summer be depended on to give a good sprinkling of flowers, which are very useful, for even with the wealth of bloom at that season. Bouvardia flowers are to be appreciated. With the advent of the first double-flowered variety, Alfred Neuner, this section of Bouvardias was thought to have a very great future before it; but Alfred Neuner still remains the only one of its class grown in any quantity, for the one that made its appearance—the pink-flowered President Garfield—was not sufficiently decided in tint to make much headway; while the bright-coloured forms with double flowers—Hogarth fl. pleno, Sang Lorraine, Victor Lemoine, Triomphe de Nancy, and the double-flowered fl. pleno—have never been grown to any great extent. Of single kinds the white blossoms, Humboldtii corymbiflora, somewhat upright, vigorous-growing form, with long-tubed, Jasmine-like blossoms that are deliciously scented, is good, the only drawback being that the tube of the flower is weak, and from its length liable to be broken. The variety Purity is of dwarf habit and with a shorter tube to the flower than the preceding. The white are Bridal Wreath and Veilandi, both of which are, however, liable to become

tinged with pink. Of bright-coloured blossoms far and away the best is President Cleveland, but other good ones are elegans and Dazzler. The salmon-pink sport from President Cleveland—Mrs. Green—is, except in colour, the counterpart of its parent; while Priory Beauty and rosea multiflora are also good pink-flowered kinds. The sulphur-tinted flavescens adds variety, while two species, triphylla and loiantha, are both pretty bright-flowered kinds.

NOTES AND REPLIES.

The Stag's-horn Fern.—I have a Stag's-horn Fern in a 48-pot which has grown well in a cool greenhouse, and has perhaps a dozen leaves or fronds. Do you think it requires repotting? And, if so, is the right time to do so, and what would be the most suitable soil and pot to put it in? There is a brown shield covering the whole of the pot. I tried (unsuccessfully) to turn it out of pot, but could not move it.—F. HERVEY.

[The ordinary Stag's-horn Fern (*Platycaerium nleicoorne*) is the only species of this family that will thrive well under cool treatment. It may be grown on a block of wood without the aid of any soil, the spreading shell-like basal fronds as they decay providing the material for the roots to spread into. It is, however, advisable to give them a little extra assistance. When grown in pockets formed of virgin cork, fibrous peat and Sphagnum Moss are the best materials, or if fixed on a block of peat the roots will spread through and form young plants on the opposite side, and eventually cover the whole surface of the peat. After being well established a little fresh material may be pressed in behind the fronds from time to time. The roots will soon take hold of the new Sphagnum. This Fern should be more extensively cultivated, for there are few that will succeed so well in a dry atmosphere. It may also be kept fairly dry at the roots. Over-watering will do more harm than being kept on the dry side. In an ordinary conservatory it will require very little water indeed during the winter. It may be grown fully exposed to the sun, but a slight shade during very bright weather may be recommended, as the fronds will keep a deeper green.]

May flowers in conservatory.—I have an unheated conservatory facing south, and am anxious to have a good display of flowers in next May. I should be much obliged if you would give me a list of things that, if potted now, would make the greenhouse bright at that time?—BELLE ISLE.

[It is unfortunate for you that in May you will miss all the best of the Narcissus family, which are admirably adapted for pots and the embellishment of the conservatory. You may, however, try such late-flowering kinds as Grandee, poetiens recurvus, and Queen of Spain. If you can pot them and place outdoors under a north wall, so much the better. Of Hyacinths you have a better choice, and may select any colour you prefer. The Mny-flowering Tulips will suit you exactly, also the Parrot kinds, keeping all of them outside as suggested above. The Spanish Irises should be potted at once and placed in frame about the end of the year, and, in like manner, the beautiful Azalea mollis, which, if similarly treated and housed in January should come in well. Such Anemone as fullens, and the beautiful forms

of Anemone hortonsis are also good. Other useful plants are *Dielytra spectabilis*, Solomon's Seal, and *Anemone sylvestris*, *Fritillaria Meleagris*, *Muscari conicum*, and any of the beautiful varieties of *Primula Sieboldi* are well adapted to the purpose, and are quite hardy. With a little care Lilacs could be added, while such hardy herbaceous plants as *Doronicum* and the early-flowering *Columbines* may all contribute to a good display at the time stated. The whole of the bulbous plants will be quite safe plunged in ashes till required. Apart from the plants named, some of the early Flag Irises would also be most useful if grown in pots.]

Fast-growing climbers for unheated greenhouse.—There are several good things for this purpose, the best being *Passion-flowers* (blue and white), *Plumbago capensis*, *Habrothamnus elegans*, and scarlet Trumpet Honeysuckle (*Lonicera sempervirens*). Of Roses, good whites are Climbing Niphetos and Lamarque, and yellow, *Celine Forestier*, *Bouquet d'Or*, *William Allen Richardson*, or *Gloire de Dijon*. A suitable compost for the tubs in which you propose to plant some of the above would be fibrous loam, 3 parts, well-rotted manure 1 part, with a dash of silver-sand. See that the tubs have three or four large holes in the bottom, and there should be 2 inches or 3 inches of crocks. The turfy pieces of loam which usually abound in good compost should be placed immediately upon crocks. Stand the tubs on bricks, so that water can pass away and air enter the soil. You can plant any of the above at once, and we should advise you to procure pot-grown plants in all cases.

Lapagerias.—"Nice things, but they want a deal of heat," was the verdict of a man who had been shown cut blooms of *Lapageria rosea* and *L. alba*. They do not need a deal of heat, and, what is more, the blooms in question were cut from a covered-in portico between a greenhouse andinery (beated by a couple of 4-inch pipes), having a door out of it to the garden. The mistake that *Lapagerias* want a lot of coddling is only too common, and several people I know labour under the belief that their houses are unsuited to them, because they have only heat necessary for the general stock of greenhouse plants. It is worth remembering that in early autumn when plants are abundant heat is seldom needed. Plant them in loam and peat, be sure the drainage is perfect and the roots have plenty of room, and success will follow.—W. F.

A note on Primulas.—A removal from cold-frame to greenhouse of these useful winter-flowering plants is now needful. A shelf near the glass, where they will not be dried up or too much influenced by ventilators, is the best place for them, and, now that blooms are not far distant, one may give stimulants like cow-manure or weak guano-water several times a week with advantage. Do not, for the sake of getting extra plants in the house, cram them together, as this will result in the foliage being crushed. Neither is it needful or wise to apply too much heat, or to give too much light, and not over-much moisture must be studied.

ROSES.

ROSE CRIMSON RAMBLER.

THE more naturally this Rose is allowed to grow the better will it flower, as may be seen by our illustration. Where the plants have attained a fairly large size some of the growths more than two years old should be cut out about February and March. Those that are hard and well ripened should be allowed to remain, while any that are soft and pithy should be cut clean out. Upon the two-year-old wood will be a number of laterals from 4 inches to 15 inches in length. If these are very numerous some may be entirely removed, leaving the others from 3 inches to 12 inches in length, according to their strength. We saw lately some fine plants of Crimson Rambler in the open garden, where this Rose is most effective and thrives best. Standards of this Rose make a glorious show when in bloom, as the growths bend over naturally umbrella fashion. The three newest Ramblers—Aglaja, Euphrosyne, and Thalia—do not at first flower so freely as the Crimson Rambler. Leave these unpruned for two or three years and they will flower as freely as one could wish, if the same treatment meted out to Crimson Rambler is given.

Mrs. Erskine, Broomley, Montrose, N.B., says:—"This photograph I send you I fancy might be considered suitable for your pages, as it shows what fine growth the Crimson Rambler will make in these parts. It was planted in the spring of 1900 over the back of my gardener's lodge, the situation facing east."

PERGOLA FOR ROSES.

Will you please advise me how to proceed in the above, and as to construction? I wish to make a pergola from my upper (croquet) lawn to tennis-court. The distance is about 18 feet, on a slight slope. The width I could arrange from 3 feet 6 inches to 4 feet 6 inches. In this district fir props (sained pine wood) are largely imported for coillery use. The lengths vary from 7 feet to 8 feet and 11 feet to 12 feet, and of varying diameter. My idea is to put in five props on each side, 9 feet high, 5 inches to 6 inches at the larger end, tapering about 1 inch to the top, 2 feet in the ground, at about 4 feet 6 inches apart; then run split props along the top on either side, and over the walk from prop to prop crossways, to give rigidity and support. Now as to the Roses. There would be ten props. Should I plant a climbing Rose to each, or how many? The situation is rather exposed to heavy winds from the sea side. Roses do very well with me if they have moderate shelter. I should like a series of climbing Roses to last well through summer. The south-west side of the pergola will be the more exposed to the winds, and the more delicate plants might go on the sheltered side. I want W. A. Richardson, Crimson Rambler, and Aimée Vibert, all of which do well here; but Gloire de Dijon does not perfect its blooms. Are Aglaja and Thalia quite hardy? I see Euphrosyne well spoken of.—MONROSE, N.B.

Rose Crimson Rambler in the garden at Broomley, Montrose, N.B. From a photograph sent by Mrs. C. Kennedy Erskine.

[The details of construction are quite simple. The Fir poles you speak of will do quite well. We would suggest the stouter poles for the uprights. Do not bark them, save that part buried in the earth, and this so that it may be tinned or well dressed with Stockholm tar, say, two coats. On the top of uprights you will need fix a length of similar material lengthwise on each side to carry the cross bearers, and it may also be prudent to fix these to the uprights with hoop iron to keep them in position. In cutting the cross pieces for the top, let them extend at least 1 foot on either side beyond the actual ground width. This will give an importance to the whole, and at the same time dispense with anything of the straight line pattern. You will, of course, fix the top bearer pieces in position. If the sides can be enclosed, fix some of the small Larch tops crosswise or in diagonal form, allowing the mesh at least a clear 12 inches at the points. So placed, the Roses may be trained thereto, and so given that greater freedom so essential for the well ripening of the shoots. This is not usually done in the pergola, but in your case, and with only medium-sized uprights, there would be necessity be much bunching together of the main branches which is an objection.

Where larger and brick pillars are used for uprights, there is room for a free opening of the shoots in carrying them up. Let there be some sort of proportion between the main poles or uprights and the top cross bearers, as it is not easy to replace those when decay sets in. The cross bearers should be about 2 feet apart, and may be intersected by smaller ones longitudinally, if you think fit. Endeavour to obtain all the width you can, as a narrow pergola is not prepossessing. By adopting the trellis-like sides you will not only be better able to train the Roses, but you can have a greater variety also. Plant strong climbers at the poles, and medium ones on the trellis. The following are useful sorts and strong growers: Mme. Berard, in lieu of Gloire de Dijon, of which you speak; Cheshunt Hybrid, early; Longworth Rambler, crimson, good late kind; Frances Bloxam, salmon-pink, very free; Crimson Rambler; W. A. Richardson; Aimée Vibert; Alister Stella Grey; L'Idéal; Gustave Rejis; Aglaja, very free and vigorous, and fine foliage; Thalia, quite hardy and vigorous. The following will be best for the trellis portion: Mme. Jules Grolez; Mrs. W. J. Grant, climbing var.; Souv. de Mme. E. Verdier;

yield better blossoms in autumn from the Brier stock.]

Climbing Roses for enol greenhouse and south side of a house.—I should be very much obliged if you could recommend me some good climbing Roses for above purposes. The greenhouse is 50 feet by 10 feet, lean-to, and faces south-west. I want to grow five different Roses (Teas or H.T.) on the roof, so as to have variety; so they must not be too strong-growing, as the space will be limited. I should like red, pink, and yellow. Would L'Idéal do in such a place? Is Pink Rover too free-growing for a confined place? How far from the glass should the wires they are trained on be? I also want some free-growing hardy Roses for the south side of the house—six strong and six moderate growers in red, pink, and yellow (not Asyrhires)? Also, what Roses could you recommend to make good high bushes if grown in pots in a cool greenhouse? Could one get half-standard Roses to make handsome plants, such as would stand the ground (in pots) to hide staging?—BROOMLEY, N.B.

[As you do not desire the kinds to be too vigorous, you will find the following selection a good one:—Pink: Climbing Mrs. W. J. Grant, Mme. Abel Chatenay. Yellow: Billiard var. Barré, Bouquet d'Or. Red: L'Idéal or Mme. Desir. Mme. Abel Chatenay would take a little longer to cover the roof, but it is a hardy Rose for the purpose. L'Idéal would be a very good one for a reddish yellow, and its buds are beautiful. The wires are usually placed about

Viscountess Folkestone; Namie, rosy-carmine and yellow base, perfect form; Mme. Abel Chatenay; K'Barney; Lady Battersea; L'Innocence. In these two sets you have some of the best kinds for the purpose you have in view.]

NOTES AND REPLIES.

Rose Mme. Eugénie BULLET.—The colour of this fine Hybrid Tea is still not to describe. Catalogues give it as bright yellow, shaded rose and carmine. This, I think, gives a wrong impression, although there is undoubtedly yellow in the flowers. Yellowish-salmon seems to me more the tint. Anyhow, it is very charming, and one that should be in every collection. The flowers are borne erect, which is a valuable trait of the popular Hybrid Teas.—ROSA.

Roses for exhibition.—Would you name twelve Roses suitable for exhibition? The plot of ground I propose planting them on faces east, but gets the sun till 12 o'clock. I should like those that are free-flowering and autumn bloomers. Expense is a consideration.—GARDENER.

[The following dozen would, we think, meet your requirements: Caroline Testout, Charles Lefebvre, Comte Raimbaud, Frau Karl Duschki, La France, Marie Baumann, Mrs. John Laing, Mrs. Sharman Crawford, Marquis Litta, Mrs. W. J. Grant, Pride of Waltham, and White Lady. Procure them on the seedling or cutting Brier, or they

1 foot from the glass. If possible, we should advise you to prepare a good border in which to plant the Roses, and also obtain well-ripened pot-grown plants to plant out for the purpose. Those known as extra sized would be best. Should there be a bench around the side of your greenhouse you could train on to the roof kinds even less vigorous, such as "Perle de Jardins (yellow), "Liberty (crimson), and "Bridesmaid (pink). These, of course, would need to be grown in large pots. We strongly recommend such Roses for small houses, as they never fail to give a quantity of buds and beautiful blossoms. Pink Rover is scarcely a suitable pink Rose for indoors, although a beautiful kind for an outside pillar or wall. Six strong climbers for a south wall are:—Red: Waltham Climber No. 1, Cheshunt Hybrid. Pink: Mme. Marie L'vallee, Climbing Captain Christy. Yellow: Mme. Berard, Céline Forestier. Six moderate growers for same wall are:—Red: Gloire de Margot, "Grass an Teplitz. Pink: "Mme. Abel Chatenay, Mme. Wagram. Yellow: "Marie Vaux Houtte, Soleil d'Or. These kinds marked with an asterisk would make good high bushes for your greenhouse, adding The Bride and Caroline Testout. Half-standards of good free

inds would grow well in pots, and they are very beautiful when in full bloom. Any of the kinds named above would be suitable for those. The strongest growers develop beautiful semi-erecting heads.]

OUTDOOR PLANTS.

THE TREE-PÆONY.

The Tree-Pæony must have an open spot away from the shade or shelter of trees; but, if possible, it should be sheltered from north and east winds, which, as a rule, prevail in spring, about the time when the plant is pushing out new growths. If should be the aim of the cultivator to retard the growth as much as he can, and, if the locality is naturally warm, the Tree-Pæony will require particular attention, otherwise a sharp frost in April will destroy the growth and bloom. It is a common practice in many places, and a very good one, to protect the plants by a movable glass case, or by sitting up around them a temporary framework, which are placed muslin, paper, or other thin protecting material during the most delicate time—that is, from the time when the young shoots begin to lengthen till all fear of frost is over. If a plant is taken by frost, without protection, then the best thing to do is to screen it at once in the morning sun, so that it may thaw gradually. In some districts no protection is necessary, and this is the case especially in upland gardens, which are colder than those in valleys, and, therefore, the vegetation does not start so early. Scarcely any amount of snow during the dead of winter will hurt this Pæony. Some people plant on the north side of hills, so as to retard growth, in such situations have a retarding effect, inasmuch as the young wood does not grow through want of sufficient sunshine. Pæonies look best when isolated on a lawn, not near a shrubbery or a group of some sort, but so placed that they appear to be in some connection with one or the other, as the case may be. Being deciduous, a spot should be chosen for them where they would be backed up by evergreens for the sake of the winter effect. The Tree-Pæony should be

FORCED INTO BLOOM in early spring with very little trouble, in order to get fine blooms. Forcing must be gentle. The plants set aside for forcing should be strong and well rooted, and the shoots should be well ripened. They will, of course, be in pots and in cold frames. About the latter part of January or the beginning of February a few plants should be taken to a house slightly heated; for a week or they will require no attention, as the buds will be dormant; but as soon as the latter begin to show signs of swelling care must be taken that the plants do not suffer from drought. At this stage they may be taken to a house where the mean temperature ranges from 50 degs. to 55 degs., and in this atmosphere the buds will swell quickly and the shoots lengthen, till about the end of February or early in March they will be showing bloom. During this slight forcing period the plants should be watered daily if the atmosphere feels dry; but when in bloom a dry atmosphere is best in order to preserve the flowering period as long as possible, which, in a cool conservatory, will extend over twelve weeks when well managed. They make noble vase ornaments for rooms, as a fair-sized plant will carry from six to a dozen

blooms and buds. All the sorts may be forced equally well; but those which have the brightest or the most delicate colours are the best. Such sorts as Reine Elizabeth, Mme. de Vatry, Mme. Laffay, Lactea, Louise Moncharlet, and Lord Macartney are particularly suited for forcing.

THE BEST SOIL for Tree-Pæonies is a deep loam, enriched by manure. It is most important to plant well at the outset, for no plant resents root interference when once established so much as the Tree-Pæony, and that is why it is so difficult to transplant it without ill effects. When planting, a hole should be dug 4 feet wide and a yard in depth, removing all the soil if not of good loam. Put a good layer of rubble at the bottom for drainage, and then, with a layer of turfy sods on the top of this, put in the

because they do not throw up suckers in the way in which the common *P. officinalis* and others do. The grafting should be done any time between August and the middle of March, but French propagators prefer to do it between the second week of July and the second week of August, in order that the union may take place before winter sets in. An expert propagator thus describes the operation: Select (he says) some good tubers of some herbaceous Pæony, then slit each tuber from the crown downward, about 2 inches. Cut the scion in the shape of a wedge and insert it in the slit made in the tuber, taking care that the bark of both the tuber and scion fits exactly; then bind with bast and wax in the usual way. Put the grafted tubers in deep pots, cover with soil to the top of each tuber, and place the

Tree-Pæony Mme. Stuart Low. From a photograph sent by Mr. R. G. Pringle, Charleton Gardens, Colingburgh, Fife.

soil; after a week's interval, so as to allow the latter to settle, plant your Pæony. The best, and, in fact, the only time for planting is autumn, during September or October. Nursery plants are always kept in pots, and at planting time the roots should be disentangled and spread out. Being of slow growth, Tree-Pæonies require no pruning, except removing dead shoots. They seem to flourish in any fairly good soil. In several localities the largest and handsomest trees grow on sloping banks of light and deep soil, well exposed to the sun and protected from fierce winds.

PROPAGATION.—The usual and best mode of increasing Tree-Pæonies is by grafting them on the fleshy roots of the herbaceous kinds, but they may be also raised from seed or multiplied by division of the root, by layers, by cuttings, and by budding. In grafting scions on roots, *P. officinalis* and hybrids from it are preferred,

pots in a frame, which must be kept close and rather dry. If the operation is done in July or August the scion will be united by September; by October the stock will have developed roots, so that in this way the plants are able to withstand the winter well in a cold-frame. After they have made one season's growth under frame treatment they should be planted out and treated as established plants. Layering is another simple way of propagating Moutans. If the previous year's shoots are tongued and pegged down in the autumn they will throw out roots the first year from each bud, and during the second year after layering may be safely removed from the stool. Propagation by budding and cuttings is also carried out, but it is found that plants raised from cuttings remain in a weak state for several years. Dividing the roots for increase of stock may be done any time during autumn, care being

taken that each division carries a few fibrous roots. Seedling raising is not much practised in this country, because it is seldom that seeds are thoroughly ripened.

CROWN ANEMONES IN SCOTLAND.

At this season, when flowers are becoming scarce, I do not think people sufficiently appreciate this lovely plant. At present I have some plants, sown in the beginning of April, just begun to bloom and covered with buds. Another lot that commenced to flower in March, and has gone on ever since, is still flowering from the roots that died down early and have sprung up again. The blooms on it were splendid, 3 inches and 4 inches across and many more, with stems 2 feet high, in every variety of colour and blending of colours, doubles, large singles, fringed, etc. I have at present beds in all stages—seedlings which will bloom very early, and some later on. They are so easy to grow, and need no care or attention, save, of course, to remove

At any rate, bulbs left for a few years without being lifted are often without flowers, proving that an annual lifting and replanting in autumn are beneficial. I know that many theories are advanced every year as to the cause of Daffodils failing to bloom, but from my own experience I have to acknowledge that my worst failures have been from bulbs left too long in the ground, and which have become thickly matted together.—W. F. D.

NOTES AND REPLIES.

Panacratium maritimum.—Would you kindly let me know what is the correct treatment for *Panacratium maritimum*? I have had it some years in my garden in a warm place, where *Belladonna* Lilies do well, and although it has increased tremendously, it never flowers. Originally, for the first year, it was in a greenhouse, and the second year it was planted out.—WALSH.

[To be successful in flowering this plant, which, by the way, is not characterised for freedom of blooming, a definite season of rest, wherein all moisture should be rigorously excluded, is necessary. Grown in quite a warm

the same. I am giving the bed a good dressing of peat. The bank, which faces east, gets a good deal of the afternoon sun, and is occasionally rather dry. Could you tell me the best sorts of Lilies to plant? I do not want expensive kinds.—C. M. W.

[The following are all good kinds: *L. candidum*, *L. umbellatum*, any of the forms of *L. Thunbergianum*, all of which are dwarf—i.e., 12 to 15 inches or so, *L. pomponium verum*, *L. tigrinum* and its variety *Fertense* and *F. E. pl.*, *L. auratum*, *L. speciosum* and its varieties *roseum*, *rubrum*, and *album*; *L. croceum*, *L. testaceum*, and *L. Martagon* are all good, easily grown, and inexpensive sorts. Plant all the kinds about 6 inches deep, save *L. candidum*, which may be just half the depth. This last may be put in at once; the remainder may be planted at any convenient time for some weeks to come.]

Artificial manures.—I should be glad of information respecting the usefulness of artificial manures for a flower garden? Also, what kinds are best to use in a garden which is not heavy, and how and in what proportions should they be applied? Do you advise artificial manures for Rose-beds?—S. C. R.

[Whilst it is an undoubted fact that no artificial manures can adequately supply to plants all the food that animal manure furnish, yet they are useful substitutes, and where animal manures cannot be obtained, then of necessity they must be utilised. All manures must contain the three primary plant food elements—phosphate, potash, and nitrogen—and generally, in artificial manures, these are best found in bone-flour (superphosphate, Kainit (potash), and nitrate of soda or sulphate of ammonia (nitrogen). It is best to purchase these separately from a manure merchant, to mix the two former in equal quantities, well breaking them up fine on a hard floor, and then to apply them early in the winter to soil, at the rate of 6 lb. per rod, digging them well in. Apply the nitrate at the rate of 3 lb. per rod in the spring after growth has begun, hoing it in. This should make a good dressing for Roses, but these latter generally need a mulch of animal manure in the summer.]

Clematis Jackmani.—I have a *Clematis Jackmani* on a wall about 10 feet high, which is well furnished with top about 4 feet from the ground. Please state what the cause, and how I will get it to furnish at the bottom.—R. H.

[*C. Jackmani* flowers on the young or summer shoots. The aim, therefore, in pruning should be to develop vigorous young wood, which is done by cutting the summer growth back each season as soon as the frosts have disfigured the plants, say in November, to within about 6 inches of the soil. You ought to then mulch the surface with some rotten manure.]

Rudbeckia Sunset.—This—one of the annual *Rudbeckias*—has done remarkably well with me this season and is now in full bloom. As advertised, it should not have exceeded 36 inches in height, but it is nearly 3 feet. This I do not mind, as the plants occupy a space about 3 feet from the front of a wide herbaceous border and make a fine display. The plants are not at all weedy looking, but are, on the contrary, bushy, very robust, and full of bloom. The blooms are as large as those of *R. speciosa* (Newman), and instead of the rays or barbs being a fine golden-yellow, they have a rich brown band or stripe down the centre of each, which renders them very effective when the sun shines upon them. It is deserving of a position either in the herbaceous or mixed border, and another strong recommendation, from an amateur's point of view, is that it may be sown where it is to bloom about the middle of April, to be afterwards thinned out to form three or five plants in a group, leaving ample space between each for full development. During dry weather water should be supplied to the roots, and they also appreciate an application of weak liquid-manure now and again.—A. W.

Gaura Lindheimeri.—This has this season again proved one of the best subjects we have, forming good bold groups, about 3 feet from the margin of herbaceous borders. The flowers cannot be described as pure white, as they have just a suspicion of a pink shade on the petals; but this, instead of detracting from their appearance, rather enhances it. The plants, when in full flower, attain a height of rather more than a yard, and once they commence to bloom the flowers succeed each other in quick succession. I have been a great admirer of this plant since it was introduced, and raised

Tree-Pruney in a Hampshire garden. (See page 473.)

weeds. I have any place where I wish to grow them richly manured, not too deep, as they do not root very deeply. The bed is allowed to lie till any heat has gone out of the manure. The seed is sown in rows, which I find a better plan than broadcast. It is rubbed in dry soil to separate the seeds, which stick very much together, and sown on the top and a little soil sprinkled over it. I always water the bed first, and after sowing and putting soil on, press down seeds and soil with a spade. If dry give a watering in the evenings. The seedlings soon start, and after the third leaf growth much more quickly than at first. When the plants are fully grown, and just before they begin to bloom, I have well-decayed manure put between the rows, which protects them in winter. My old beds also when the foliage dies down get a little fresh soil on the top and a good dressing of old manure. E. Roxburgh, N.B.

Planting Daffodils.—"Daffodils planted close together never flower freely." I was once told, and there is a deal of truth in it.

place, and preferably at the foot of a sunny wall, the plant should do well. With growth completed, place a light over it in such a way that the rainfall does not reach the bulbs or roots, and so keep it for a period of three months at least. We get a wholesome lesson in growing this species some years ago, the ends of several rows getting what they appeared to relish—by the proximity of the hot-water pipes. The bulbs were planted in frames in rows, and each end was so superior that the thing could not be overlooked. Dryness for a long period, when heat was turned on the plants not only produced good foliage, but good spikes of bloom also, while those farther removed were of the usual pattern. Grown in pots, the plants should receive special attention in these particulars of heat and dryness, and, by keeping the bulbs near the surface, insure a fuller, or, at least, an earlier ripening. When potting or planting, plenty of sand or grit should be used, and fresh sea-sand, or such as may have been weathered somewhat, may be employed.]

Lilies for planting amongst flowering shrubs.—I am planting a bank with *Azalea* and other flowering shrubs, and I want to grow a few Lilies between

a good number from seed each year. This is, I believe, the best way to grow it, for although classed as a perennial, it is too tender to withstand the damp and cold of our winters. Mid-March is a good time to sow the seed, and the resulting plants may be treated in precisely the same manner as Asters, transferring them to the open border about the middle of May. The plants will withstand a considerable amount of drought without being apparently distressed, but when afforded water whenever occasion arises, and treated to a mild dose of liquid-manure now and again, they branch much more freely, and produce finer spikes of flower. I have also used this *Gaura* in front of shrub beds, the flowers then showing to excellent effect among the dark foliage of Rhododendrons and the like. Finally, the plant is not at all fastidious as to soil, as I have had it succeed well in heavy clayey loam.—A. W.

Seasonable notes.—This is a time when gardens, walks, etc., no matter how well they

scattering a handful or two of dry sand over and among the tubers. Dahlia roots will take no harm, and, in fact, are better left until November has set in. The foliage, if previously destroyed by frost, can be cut off, leaving about 6 inches of stem. Cuttings in cold frames should be kept well aired to prevent damping, which not infrequently destroys a whole batch of stuff if not checked in time. By well airing is not meant that the lights have to be very wide open—a space of 2 inches is ample.—D. G. McL.

Humea elegans.—On sheltered borders *Humea elegans*, with its imposing racemes, is very effective, but often it gets knocked about by rough winds and rains. Grown in a cool house in pots, this difficulty is got over, and one can prepare for next summer by sowing in the greenhouse now in well drained pans filled with loam two parts, leaf-mould and sand one part, making the surface even, scattering the seed thinly, and watering it in with a fine-rosed

tuberous-rooted Begonias. The three successive displays are most satisfactory, perhaps especially the Begonias. Their rich blossoms rise high in the centre and droop over the sides of the tub, almost meeting the sprays of Periwinkle, whose dark, shining foliage makes a beautiful background for them, and the shade of the trees seems to suit them exactly. They do best kept in their pots and plunged. The Tulips were also very beautiful. This year a robin made her nest under their broad leaves, and reared her family of five quite happily.—C. E. S.

A CORNER IN A HAMPSHIRE GARDEN.

The illustration represents a corner in a very old garden, at this time of the year made wonderfully beautiful by a mass of Clematis Flammula, with its myriads of star-like blossoms, covering like a white cloud the top of the gateway and old wall. I have found this

A corner in a Hampshire garden. From a photograph sent by Mrs. Deane, Fairfields.

may have been kept, look very untidy, due to the falling leaves. Little can be done to mend matters, until a good sharp frost throws down the bulk, when a general clear-up should be made. Some people allow the leaves to lie as they fall, digging them into the ground during the early winter. This is a mistake, as the leaves, instead of enriching the ground—the ordinary course of things—make it sour and quite unfit for profitable gardening. Far better is it to cart them away to some out-of-the-way corner and allow them to decay naturally, when valuable leaf-soil is the outcome. After the Chrysanthemums are housed, Dahlias and Begonias in beds will need attention, presuming that cuttings of Tufted Pansies, Calceolarias (shrubby), Pentstemons, Antirrhiums, etc., are in, which must first be attended to. Begonias are better lifted as soon as the frost destroys the foliage. All the soil should be shaken from the roots, and the tubers stored in boxes in a frost-proof place, putting, if possible, only a single layer, and

watering-can. A moderate temperature is sufficient for *Humea elegans* from start to finish. The seedlings must be taken out of the seed-pan as soon as possible, potted on until 7-inch or 8-inch pots are reached, a good stout stake being placed to each plant in order to secure the centre spike, otherwise the plants get top-heavy.—LEADERS.

A shaded border.—The following simple plan has given me so much pleasure that I venture to tell you of it. I have a border on two sides of my small garden, facing north and west, which is so much overshadowed by trees and impoverished by their roots that I cannot expect flowers to do well in it. Happily, it is thickly carpeted by the large blue Periwinkle. But in order to get a little more colour I have placed among these at intervals eight tubs (the half paraffin casks so often described in your columns), and these are filled (1) with Crocuses of all colours, (2) with May-flowering Tulips, planted beneath the Crocuses, and (3), when the tubs have been removed, with

season specially unfavourable to Clematises of all kinds. Many have died altogether, and even the strong-growing Clematis in the picture (taken in October, 1901) is not nearly so good as usual. French Marigolds, Petunias, Nasturtiums, on the left, with a background of Dahlias, Hollyhocks, and Sunflowers, make this a very gay corner, an old Fig tree covering the wall behind the flowers. M. DEANE. Fairfields, Farcham.

Verbena venosa.—Some twenty or more years ago this was far more grown than now. I have used it in the mixed border during the last two or three years in large masses with the best results. It goes on blooming far into the autumn, and is most useful for cutting from. Some plants of it have stood out safely where the roots had run under some stones. I find it best to take up a portion of the old plants, wintering them in boxes in a cold-pit.—F.

CHRYSANTHEMUMS,

KEEPING CHRYSANTHEMUM FLOWERS.

ONE of the best qualities which Chrysanthemums possess is the long time they will remain fresh, either growing on the plants or in a cut state; still, much to the disappointment of many growers for exhibition, they often fail to keep long enough. This is, however, very often owing to not knowing how to manage them properly. Blooms are much more difficult to keep fresh in the south of England than they are in the northern counties, as they develop more quickly in the south than in the north. The greatest trouble growers situated in the northern counties have to contend against in many seasons is the non-development of the flowers naturally in time for the shows. Those possessing the darkest shades of colour, namely, the chestnuts, bronzes, and the deepest blues, retain their freshness for the shortest period, while the primrose, the white, and the yellow shades continue the longest in good condition. Some growers cut the blooms when expanded and strive to keep them a long time by placing them in dark closets in rooms in bottles of water, but they can be kept longer by judicious management upon the plants.

To have blooms in the best possible condition on any given date, four days previous is quite soon enough to cut them. If cut earlier the florets lose their necessary solidity, and in consequence are not so large as they otherwise would be; this is particularly noticeable in the Japanese section. It is useless to cut the blooms after they commence to decay in the hope of arresting their fading; when cut they should be perfectly developed, so that the solidity of the lower florets may be maintained. An experienced person can tell better by the feel of the lower petals than anything else when the blooms should be cut; they should be crisp and solid, not soft and flabby. When this occurs the white varieties will soon assume a pink tinge, and in some other varieties a faint brownness of the lower florets points to waning beauty; therefore, when the centre of the flower is developed and the lower florets fresh, the bloom will be right, and should be cut with a long stem, say, 12 inches, so that a small portion can be cut off every day. Place it in a bottle previously filled with water, amongst which a little salt or sulphate of ammonia has been mixed, three-quarters of a tablespoonful of the former to three half pints of water. It matters not whether the water be hard or soft. Half the quantity of sulphate of ammonia will suffice. Place the bottles in a cool, slightly darkened room having a dry atmosphere. Allow the blooms to remain on the plants until required, or at least two days before, when they may be cut with safety and treated as directed. The moment the blooms are at their best remove the plants to some cool structure which can be partly darkened and where air can be admitted freely. A potting-shed having a northern aspect, Mushroom-house not in use, coach-house, or, in fact, any place having the necessary requirements—viz., coolness, dryness, and partly excluded light—will be suitable.

EARLY CHRYSANTHEMUMS AT THE N.C.S. OCTOBER SHOW.

IT is only within the last few years that encouragement has been given to the early-flowering Chrysanthemums by the National Chrysanthemum Society, at least when not disbudded, in which form these flowers look best. A few classes were first tried as an experiment, and so well were they filled that others were subsequently added. Bunches of non-disbudded sprays of blossoms were prominent at the show, which began on October 7th. These appeared to create more interest in the minds of visitors than did the large, severely disbudded exhibition specimens. The latter, in most instances, were the result of an early and selection of what are generally termed mid-season or November-flowering varieties. As such they could not be regarded in the same light as they would be a month later, as many of the blooms were lacking in colour, and of somewhat indifferent form. It seems a pity

to encourage flowers of this character. Sufficient interest would be felt in a show of naturally early Chrysanthemums grown in the open air without disbudding, as this would show the value of these sorts. There is a brilliant future for the early Chrysanthemums if raisers and distributors of new varieties will only see that the right kinds are put into commerce. We have had instances in which plants and blooms have been placed before the floral committees of the N.C.S. and R.H.S., and the varieties certificated as early-flowering ones, and this recognition of their merits has been made in the closing days of September. On growing these same varieties and extending to the plants treatment as noted out to others which are really early-flowering, the result has been very disappointing. Sorts which were certificated last season, at the time of writing (October 15th) are not yet in flower, and if the weather remains open, cannot possibly be in full bloom until the end of October or early days of November. These facts prove how necessary it is to have the flowers which are submitted to the respective floral committees of the N.C.S. and R.H.S. exhibited in an undisbudded state, as this would necessarily represent the different varieties flowering from terminal buds. It is only in this way that it can be satisfactorily determined whether a plant is an early-flowering variety.

The bunches of Chrysanthemums staged in the various competitions at the October show of the National Chrysanthemum Society at the Royal Aquarium were all true early-flowering kinds, as they were all grown without disbudding, and in consequence flowering from terminal buds. Mme. Marie Masse, rose-pink, and its beautiful sports, Crimson Marie Masse, chestnut-bronze; Ralph Curtis, creamy-white; Robbie Burns, salmon-rose; and Horace Martin, rich golden-yellow, were more often in evidence than were any other varieties. These five sorts may be said to represent the ideal early-flowering Chrysanthemum, as the plants have a sturdy branching habit of growth, flower freely, and also have a good constitution. Their period of flowering commences in early August and continues well into late October. Ivy Stark is a charming sort, reminding one of Source d'Or, and may be said to be an early form of that excellent sort. Bronze Prince is but little known, and may be described as a rich bronze, tinted carmine. Lemon Queen is a rich, deep, yellow flower, and the plant is a profuse bloomer. Its form is good, and the flower has a long footstalk. Of Harvest Home too much cannot be said. This season it has done remarkably well, the flowers are large and their colour a rich and pleasing shade of crimson, tipped golden-yellow. September Beauty is a bronze sort, its height not exceeding 2 feet, and its habit is also good. Other good sorts were Chateau St. Victor, amaranth; Henri Yvon, rosy-salmon on yellow ground; Edith Syrett, magenta; Francois Vuillemet, lilac-pink; and Milo Guindudeau, pink.

EARLY-FLOWERING CHRYSANTHEMUMS.

WHAT a gorgeous display these have been making for the past few weeks, and will continue to do so for some little time longer, should there be no frost to destroy them. The earliest to bloom were, as a matter of course, the small-flowered Pompons, such as Piercy's Seedling, Little Bob, Fred Pele, White Pot (a bronze-coloured variety of the last-named), Alice Butcher, Leeds, Toreador, Flora (yellow), L'Ami Conderchet, and Golden Floece. Following close on their heels were the early Japanese varieties, such as Mme. Desgrango, G. Wermig, Queen of the Earlies, Mme. M. Masse, also the crimson and orange-flowered forms of the last-named variety, and Gladiador, a dwarf and, if anything, more free-flowering sort than Mme. M. Masse, and similar in colour. Then came Harvest Home and Ambrose Thomas' two beautiful free-flowering varieties, Yellow Boy, Mrs. Rice, Mad. C. de Brailles, Vice-President Hardy, and Crimson Queen. The next to open were Countess de Cariel (an exceedingly pretty variety), James Salter, Crimson Pride, Rycroft Glory, and M. A. Galy. All the above have been grown in narrow

borders in quantity by the side of the kitchen garden paths, two rows of plants in each, and arranged so that they stand 2 feet apart. They grew vigorously, and for a few weeks before flowering were assisted with liquid-manure. They have without exception flowered most profusely, and have brightened up very considerably what is often an unattractive part of the garden at this season of the year. When grown in the manner described, the long lines of plants in full flower present a beautiful piece of colouring, and it is really the best way of cultivating them if a fine and protected display is wished for. A. W.

ORCHIDS.

Odontoglossum Wallisi can be grown in a cool-house, 50 degs. at night, treated in every way as for *Odontoglossum crispum*. When the plant requires repotting place some Bracken-roots instead of crocks at the bottom of the pot, and use the compost as advised above. It is only of botanical interest.—H. J. C.

Leaf-soil for Orchids.—Many thanks for your reply to my queries, especially as to the cultivation in Belgian leaf-soil, of which I have got a sample basket, and propose giving it a trial. I am told to use only a single crock for the leaf-soil, and pot moderately firm. Is this right?—SAM C. BUCKLEY.

I am informed that leaf-mould is now used in the cultivation of Orchids, and as I have seen no mention of it in GARDENING, I shall be glad if you would give me some information regarding it—that is to say, for what Orchids it is suitable, and how applied? Also as to the sort of leaves from which the soil is made, and how it is prepared? I should imagine that leaf-mould would not be very lasting, and would have to be renewed frequently. My information of it was in a catalogue of sale by auction, which stated that *Vanda coerulea* would do well in it.—F. W.

[Whatever may have been said by other correspondents I have had no knowledge of, but as many of your queries have been replied to by me, I feel that I ought to state that the use of leaf-soil in the cultivation of Orchids by amateurs is a very risky business. Only those who are thoroughly acquainted with, and have had a long experience in the cultivation of Orchids should attempt its use, and even then many good cultivators of Orchids fail with it. Some writers surmise that watering is the key to the successful culture of Orchids in leaf-soil. My own experience convinces me that the situation and atmospheric conditions under which the plants are grown have a great deal more to do with success in the cultivation of Orchids in leaf-soil than anything else. I have proved that in the unfavourable conditions surrounding our large towns it is impossible to grow plants as some advise wholly in leaf-soil, especially "Belgian leaf-soil." If leaf-soil is used at all it should be thoroughly prepared "English" Oak or Beech-leaves, and then mixed with equal portions of fibrous peat, Sphagnum Moss, and rough sand, sufficient to retain it in a porous state. Water must even then be given sparingly, and with due caution. It should be pressed moderately firm. With this caution I would advise you to keep a sharp look-out, and, if detrimental effects become apparent, immediately transfer your plants to the tried mixture of about equal portions of fibrous peat and Sphagnum Moss.—H. J. C.]

Masdevallia picta.—This is a scarce and rather difficult subject to manage. Its small size necessitates its being planted in shallow pans, so that it can be suspended close to the roof glass. It is a small-flowered kind, so that it only displays its flowers to the best advantage when hung up where it can be seen. The pan should be filled one-third with broken crocks, the potting compost consisting of equal portions of fibrous peat and Sphagnum Moss, pressed moderately firm. It will do very well in the cool-house during the warm months of the year, but from, say, October to March it should be placed in a house that does not fall below 55 degs. during winter. The whole of the small-growing *Masdevallias* are best grown under warmer conditions during the winter months of the year.—H. J. C.

Request to readers of "Gardening."—Readers, both amateur and in the trade, will kindly remember that we are always very glad to see interesting specimens of plants or flowers to illustrate, if they will kindly send them to our office in as good a state as possible.

TREES AND SHRUBS.

ESCALLONIAS.

THE Escallonias are mostly natives of South America—chiefly Chili, Brazil, and Peru. Unfortunately, they are not quite hardy, save in favoured districts close to the sea, and even then they are often cut down in severe winters, but shoot up again from the bottom in the returning spring. Escallonias are, as a rule, of rapid growth and being easily propagated they have become common garden shrubs and can always be safely recommended for walls. The following are the best of the family:—

E. EXONIENSIS is a hybrid whose parentage is unknown. It is of compact habit and flowers freely. The tube of the flower is pink, the expanded portion of a paler hue.

E. LANGLEYENSIS.—This, a hybrid between *E. Philippiana* and the form of *E. macrantha*—known in gardens as *E. m. sanguinea*—is a pretty addition to hybrid shrubs. It has the growth and character of *E. Philippiana* with a profusion of rosy-pink blossoms in small trusses upon every shoot. The leaves are dark shining green. There are few finer shrubs than the popular

can be easily increased by cuttings put into a cold-frame towards the end of the summer.

E. PTEROCLADON is a very free-flowering kind with white and pink flowers, while

E. PUNCTATA has dark red flowers somewhat resembling those of *E. rubra*.

GARDEN PESTS AND FRIENDS.

Black Currant-mite.—I have a number of Black Currant-bushes, which are full of those round buds which I call useless. I would be very pleased if you could give me any information how to restore them to a healthy condition? They were replanted and thoroughly manured a year or two since, but they have gradually grown worse. I suggest pulling them out. If so, should the same ground be planted with Black Currant-bushes?—**BLACK CURRANT.**

[Your Currant-bushes have been attacked by the Black Currant-mite that can only be seen with a strong glass or microscope. Once a bud is attacked not only is it practically destroyed, but it is a centre for the breeding and diffusion of the mite. For these reasons it is advisable to gather any buds that are bare and burn them. That it may be difficult to combat this pest by bud-picking only in a large breadth is probable, but in small gardens it has been successfully done. All who grow Black Currants should examine the bushes now

search it well. If the part be in a pot it is best to lay it on its side: then there will be no chance of the beetle falling into the earth in the pot, and, perhaps, escaping detection, for they remain perfectly quiet as if dead for some little time. Small bundles of bay or dried Moss tied to the stems of plants or laid on the earth make good traps, as the weevils find them convenient places to hide in.]

American-blight on Apple-trees.—I have enclosed a piece of an Apple-tree, which seems to be swarmed with the insects as on specimen enclosed. Will you please state cause, remedy (if any), as I am afraid of losing the whole of them?—**YOUNG ESQUIRE.**

[Your trees are attacked by the "American blight" (*Sobionaura lanigera*), a very common pest on Apple-trees. You do not mention the size of the trees, but if they be small enough to reach all the infected parts, the best thing that you can do is scrape off all the rough bark at the part where the insects are, and then rub some paraffin emulsion on the part with a stiff brush, working it well into any cracks, etc., in which the insects may hide. If there be parts of the trees that you cannot reach, spray them with the paraffin emulsion, and in the winter spray the trees with a caustic wash.—**G. S. S.]**

Gooseberry caterpillar.—Will you kindly allow me to tell "W. E. W.," in reply to his inquiry in GARDENING ILLUSTRATED for October 25th, about the "Gooseberry caterpillar," of the simple and effective plan I adopt here to get rid of this tiresome pest? I use carbolic acid powder, the same as used for disinfecting purposes, which I sprinkle on the ground under the bushes as far as the branches extend all round. Sprinkle it on about as thickly as one would spread gaslime, or just lightly covering the ground with the powder. Then, with a round stick or piece of cane, jar the branches so that the insects drop into the powder. The bushes must be shaken several times. It is best to do this in fine weather, so that the powder remains dry for a few days. There is no chance for the insects to get down into the earth to breed. The above has been my plan for many years, and never without success. Last year (1901) my bushes were badly infested. I adopted the above plan, and this year my bushes were all healthy, laden with fruit, but not one caterpillar to be seen. The powder will not injure the roots of the bushes if dusted over just to whiten the ground lightly, and one dressing is sufficient for the season. There is no need to dig out and burn soil or spray the bushes.—**FRED WRIGHT.**

Escallonia Philippiana.

E. MACRANTHA, which is found in many English gardens, especially near the coast. We know also of several fine specimens on walls as far north as Aberdeen which have never suffered in any way, having been slightly protected during the winter. The dark green glossy leaves of this give it a handsome appearance all the winter, while clusters of crimson flowers adorn it in summer for several weeks. There is a variety of this called *sanguinea*, with deeper-coloured flowers. Somewhat similar to it is *E. rubra*, but the foliage is not so glossy and the flowers are paler.

E. MONTEVIDENSIS (syn. *E. floribunda*) bears large clusters of white flowers. It is a late-blooming kind, and the flowers are liable to be destroyed by frost. Flowering, however, at a season when few other shrubs are in bloom it is all the more valuable. There are many seedling forms of this in seaside gardens, Ingrami being the best, and hardier than *E. macrantha*.

E. PHILIPPIANA.—This, introduced from Valdivia in 1873, is the hardiest of all, and a valuable summer-flowering shrub. It is a free-growing, rather spreading, much-branched bush with small dark-green foliage, and after midsummer is thickly studded with little white blossoms, forming when in full bloom quite a mass of that tint. It does best in a fairly open loam that is a day's ride from the

and again early in the year, and if they pick off all the infested buds great good will follow, and in time the mite may be stamped out.]

Grubs among Cyclamen roots.—The enclosed grubs were found on the underside of a Cyclamen corm, they having eaten away the whole of the roots. Can you tell me what they are, and how they may be guarded against?—**R. B. ROGERS.**

[The grubs that you find at the roots of your Ferns are those of the "black Vine-weevil" (*Otiorrhynchus sulcatus*), or its very near relative, the "clay-coloured weevil" (*O. picipes*). These grubs are very destructive to the roots of Ferns, Primulas, Cyclamens, Begonias, and various other plants. There is no means of getting rid of them but picking them out from among the roots. The best way of destroying this insect is by killing the weevils. This is not a very easy task, as they are only to be found at night; during the day they hide themselves so cleverly that it is very difficult to find them. They feed on the foliage of various plants—Vines, Roses, Ferns, etc. The easiest way to catch them is to put, while it is daylight, a white cloth under the plant they are attacking, and then, after dark, to suddenly throw a bright light on the plant. This will generally make the beetles fall, when they will at once be seen on the cloth. If by doing so you give the plant a good shake, or

VEGETABLES.

LATE PEAS.

MUCH as we abuse the vagaries of the past summer, 1902 will long be remembered as most congenial to the well-being of leguminous plants, especially on light or gravelly soils, where during very hot, dry summers they are often a complete failure from July onwards, owing to the attacks of thrip or mildew, which, unless battled with in their first stages, soon cripple the growth, from which the plants seldom recover. Gardeners who have depended upon artificial manures for this crop cannot but have been well satisfied with the results, as the frequent showers throughout the season soon washed to the roots the properties of any surface dressing. As main crop varieties Criterion and No Plus Ultra stood us in good stead throughout August and early September as heavy cropping Peas of fine flavour. Glory of Devon again did well, fully maintaining all the raisers claim for it, while for the latest supply I rely chiefly upon Autocrat, a good Pea in every respect, and on account of its moderate height easily netted where birds are a trouble, while the haulm is not so liable to be blown about as that of varieties that reach 6 feet or more. When nets have to be put on they

hinder the pods from filling so quickly as they otherwise would do. We are still (Oct. 22nd) gathering a nice dish twice or thrice a week, but the sun having less power and the days getting shorter, and rather many wet, dull days, the pods do not fill the basket like they did a month since. On July 15th I sowed Gradus, Chelsea Gem, and Carter's Daisy as a chance crop. The first has given us a few gatherings, but the other two did nothing.

J. M. B.

NOTES AND REPLIES.

Forcing Rhubarb in frames.—I have tried to force Rhubarb in a small frame, covering the crowns with stable-manure, but without success. As soon as the growths vees a few inches up they damped off.—CREE.

[You should have placed a few inches of short manure in the bottom of the frame, and on that packed the Rhubarb roots closely, then filled in with soil, watered well, and covered up the frame with mats to keep out the light. Any dark, close place answers for forcing Rhubarb, but quickness of growth will entirely depend on the heat you have at command.]

Onion-seed.—Rather indifferent reports are made as to the Onion-seed crop this season, consequent on the unusual wetness of the weather, for Onion hulhs do not like too much wet when planted for seed production. Still farther, the frequent heavy rainfall has caused much of the bloom to set imperfectly, and where fungus prevailed a further factor of injury was found. No doubt there are ample stocks of the previous season's seed on hand, but growers generally like seed of the present year for sowing. The growers of great bulbs, who save their own seed, always use fresh. Still, they generally purchase some also, as it is now becoming good practice to vary seed, as too great dependence on one and a home-raised stock is not good policy. However, whilst with some bulbs, especially of the Crimson Globe, I have had poor results, from some very fine bulbs of Excelsior sent me, each of which carried from eight to ten heads of seed, though because of the rain not so perfectly set as in dry weather would have been the case, I had good results.—A. D.

FRUIT.

APPLE ALLINGTON PIPPIN.

WHEN first brought under the notice of the Fruit Committee of the Royal Horticultural Society this dessert Apple was exhibited under the name of South Lincoln Beauty, and was then certificated as such. The purchasers, Messrs. G. Bunyard and Co., however, thought well to change the name to that of Allington Pippin, and under that name it has so far had a very successful career. It is not all the new varieties of Apples which are from time to time introduced that possess the needful qualifications to render them popular with fruit growers generally, hence the reason why so many are unheard of a few years after being first introduced to the public. This is, however, not the case with Allington Pippin, for it excited great interest the first time it was exhibited, which has increased the more growers have become familiar with its free-cropping capabilities and the excellent quality of the fruit, until it is now very largely grown in various parts of the country both for market and home consumption. It is, generally speaking, medium in size (although the first time it bore with me some of the fruits were quite large), the skin is dull yellow and beautifully streaked with red on the side facing the sun, and its whole appearance is such as to attract once command attention. It has a rather deep-set eye, a long, slender stalk set in a deep round basin, which gives the fruits a semi-pendent character as seen growing, while the flavour is rich, but quite distinct from that of either Ribston or Cox's Orange Pippins. The variety has a capital constitution, as it both grows and bears freely; in fact, so prolific is it that quite young trees will carry a good few examples. As a bush for the garden and orchard Allington Pippin can be highly recommended, and there is no doubt that it will also succeed grown as a standard. Where Cox's Orange Pippin grows but indifferently

Allington Pippin may be substituted for it with every chance of its proving a success. Its keeping qualities are all that can be desired, as some specimens stored and tested late in January were found excellent, the flavour not having deteriorated in the slightest degree.

A. W.

NOTES AND REPLIES.

Manuring Raspberries.—I shall be glad if you will give me some information as to the best way of manuring Raspberries when grown by several acres? Spit manure is bad to get and costly to apply. What artificial

Add a sprinkling of nitrate of soda early in June, and hoe it in, giving 3 lb. per rod. Fish guano, at the rate of 7 lb. per rod, is a very good dressing. Never dig deep amongst Raspberries, or even use a spade—a fork is best. Do not wait for the leaves to fall before cutting out all weak or superfluous canes.]

Two good free-bearing dessert Plums.—After many years' experience and close observation of Plums, I have come to regard Kirke's and Jefferson as two of the best dessert kinds grown, all points con-

Bush-trees of Apple Allington Pippin. From a photograph by G. A. Champion.

manure would answer well, with spit manure given every fourth year or so?—C. B.

[Even better than heavy spit manure for Raspberries is good well-decayed garden refuse. Anything that will if put into a heap to decay, and is often turned to help it decay, will make for Raspberries the best of dressing. It should be spread about between the rows in the winter, and be but very lightly forked in. In the case of artificial manures, purchase from anyone who deals in them basic-slag, Kainit, and nitrate of soda. Mix the two first together, and strew it about between the Raspberries at the rate of 6 lb. per rod, just lightly forking it in. Do that so soon as the leaves are off and the pruning is done]

considered. I am aware that many of the Gages are better in flavour, but you have to consider the size, added to which Gages are not so reliable croppers. From a flavour point of view both these are hard to beat when well grown and well ripened. Nothing can be more handsome than a dish of these, either on the dinner or exhibition table, and for the latter purpose I doubt if any two kinds are so frequently seen. Some think them tender, but I have never found them so. I have them growing in a low-lying garden on walls and Jefferson as a standard in orchard, and I find they crop as well as any I grow. Added to this, they have better keeping powers than many other kinds when gathered.—J. C. BARK.

GARDEN WORK.

Conservatory.—This house will now be very bright with Chrysanthemums and other things. As regards arrangement, have as many features and as many changes as possible. Chrysanthemums must be well grown to bear isolation. Leggy plants must be grouped, but good specimens isolated among Ferns and fine-foliaged plants are very effective. If in groups the colours should either be placed so as to harmonise, or else to form contrasts. Indiscriminate mixtures sometimes offend the person of critical taste. The arrangement must be thought over and studied with a view to produce the best colour effects. The climbers will now have been much exposed, but sprays of scarlet Tropæolum, and the variegated Cobæa scandens hanging about are light and graceful, and give a little colour in the upper part of the house. Baskets filled with Cyclamens, Chinese Primulas, and Begonias, with the sides and bottom of the basket draped with foliage are effective. In a cool-house the variegated Periwinkle and the silver-leaved Ivies may be used with considerable effect. The broad-leaved Ivy (Adiantum variegatum) is quite as useful under glass in winter decorations as more expensive tender things. The main thing to keep in mind in the management of a conservatory or show-house is not to throw more water about than is absolutely necessary in winter, to do all the watering in the morning, and to open the ventilators early to dry up the damp. Keep down fires, especially during the time the Chrysanthemums are in flower, and when the weather is mild leave a little air all night. The early-struck Pelargoniums and the old cut-down plants will now be in their flowering pots. The best loam obtainable, enriched with about one fourth of old manure, some sand, a little bone-meal, and a dash of soot will grow these plants admirably. Firm potting is essential, and the plants should stand on a stage near the glass and be watered very carefully. The house should be well ventilated without creating a draught, and a little fire used to keep up a night temperature of 45 degs. Tree-Carnations are very useful now, and may be well grown under similar conditions to the Pelargoniums. The same treatment will suit Zonal Geraniums. We have a splendid show of these now from plants in 5-inch pots that were cut down for stock in July, and left to break outside in the bush. Our collection includes most of the best and newest varieties, and previous to seeing them do so well now, I was under the impression they would not flower so well in winter.

Stove.—Let Caladins go gradually to rest by withholding water. The pots may be set on their sides under the stage. We have generally succeeded in keeping them in this way, though, of course, there are other ways. Sometimes they are shaken out, and the corms packed in sand, but they should not be exposed to a low temperature. We have sometimes purchased new varieties from continental growers, and they generally come in the shape of small dry offsets or corms, so for this purpose they must have been dried. The great thing is to get them well dried by a gradual drying-off. Achimenes are easily kept. They will do very well on their sides under a stage in a warm greenhouse. The Gesneras will take the same, to some extent, of the summer-flowering fibrous plants. When grown in pans the different forms of Gesnera zebrina and cinnabarina are very attractive, and single specimens in 4-inch or 5-inch pots make useful plants for sale for a change. Their velvety foliage and bright flowers are distinct from those of most other plants which flower at this season. A warm, low, close pit is the best place for these and similar plants. Night temperature during the rapidly shortening days need not exceed 65 degs., in some cases 60 degs. will be better. Fuel is dear, and an extra 5 degs. makes some inroad in the coke bill. The less fire-heat the less water will be required. There will be plenty of flowers, including a few Orchids, now.

Pruning wall-trees.—As soon as the leaves are down the necessary pruning should

be done. In some cases where the spurs are crowded a gradual thinning should commence and be carried on from year to year. Old Pear and Plum-trees are often barren in the centre from the spurs being so crowded as to reduce the size of the foliage and weaken the growth, which reduces the size and strength of the buds. It is a good plan when this stage has been reached in the case of Plum-trees to lay in young shoots between the older rods or branches. These young shoots when ripened will bear freely. The same treatment may be adopted with Apricots. Sometimes in old gardens the trees are of inferior kinds, and these may be cut back and grafted with better sorts. It would pay to re-graft some of these old Pear-trees with such kinds as Doyenné du Comice, Marie Louise, and Glou Morceau. Some of these large, old trees which I have in my mind's eye might be made to carry several kinds. Bergamotts d'Esperey is a delicious late Pear. It bears freely on the Quince, but I have had it good on a cut-back old tree on a south wall. All these good late dessert Pears should have a good aspect. In pruning Marie Louise it is well to bear in mind that the blossom buds are often found on the ends of long spurs, so that this tree should not be pruned so close as other kinds which carry the fruit-spure nearer home.

Forcing Asparagus in hot-beds.—This is the simplest way, though Asparagus may be forced wherever there is a genial warmth. I have forced it in boxes in the Mushroom-house, and in boxes and flat baskets in the stove or any forcing-house. Like all other forcing work, the main thing is to secure strong roots with well developed crowns which have not been previously excited. Young, well-grown roots four years old will produce very fine heads, and these young plants are easily started. The hot-bed system is the best in country places where there is plenty of tree-leaves, as the heat costs nothing beyond the labour, a consideration now fuel is dear, and the result is so good, the warmth being so genial.

Early Peach-house.—When trees have been forced several seasons they are always ready to start when the usual time comes round, and not nearly so much forcing is required; therefore the early house should be in readiness now for the start—the walls lime-washed, and the borders top-dressed, and their condition as to dryness or otherwise seen to. Peaches will take a good deal of nourishment when cropped heavily. Very little fire-heat will be required at first, as 45 degs. at night need not be exceeded till the buds show signs of moving.

Window gardening.—Roman Hyacinths that were potted early may be taken from plunging bed indoors. Colchicums or Autumn Crocuses are pretty in pots, and Primulas of various kinds will be in flower nearly all winter. Berry-bearing plants are rather pretty, and there is plenty of winter-flowering Heaths that will succeed in a cool, light, well-ventilated room where the water-pot is used with judgment. There are still some flowers on Zonal Geraniums, and the Chrysanthemums are full of bloom now.

Outdoor garden.—Finish planting bulbs as soon as possible. The Autumn Crocuses (Colchicums) are now very bright in groups in sheltered parts of the borders. Sternbergia lutea also is very bright and the flowers are lasting. It wants a deep, well-drained soil, in sunny position. Lift the roots of Dahlias and Gladioli, dry them, and store in cool place safe from frost. Daisies, Pansies, and Violas are cheap, and make a good show. Early-sown Pansies are in bloom now. For bedding, seedlings are even more effective than plants raised from cuttings. Our Pansies in beds are now very bright, and if the weather is mild will continue to flower most of the winter. All the usual hardy plants may be planted now for spring blooming. Shrubs and trees of all kinds may also be planted. One never has too many Roses, and there are so many ways of using them. Rambler Roses are now much planted, and the Crimson Rambler seems inclined to flower in the autumn. I notice several clusters of buds on some of our plants which flowered freely in the summer. The double bicolor Gorse is a desirable thing to

have in the front of dark-leaved shrubs or on the rockery (elevated a little). Sweeping and rolling must be attended to now if lawns and walks are to be kept in order, but do not remove leaves from the shrubbery.

Fruit garden.—Plantations of Strawberries should be freed from weeds and runners, if not already done, and a top-dressing of manure given between the rows. The advantage of planting a few rows of plants for the production of runners is very great. The runners may be planted now, if not already done. Our rule is to plant 1 foot apart in the rows and 2 feet from row to row. Half the plants may be removed after the first crop has been gathered. Coe's Golden Drop and other late Plums will keep some time on the shelves in a cool, dry fruit-room after being gathered, if they are not bruised or damaged in any way. Those who are thinking of planting Figs outside should select a warm, sunny wall of 12 feet or more high, and make a border 4 feet or 5 feet wide on an impervious foundation, the position to be well drained. Figs are among the easiest fruits to grow, if the roots are properly controlled. Wide or extensive borders are not required, as liquid-manure can be given when the Figs are swelling off, and on heavy soils make the border above the natural level, and check the roots if they attempt to leave the bed prepared for them. The same course should be adopted with outdoor Vines, and the fruit will ripen better and the crops be heavier.

Vegetable garden.—This is a late season in every sense of the word. Rhubarb and Sea-kale are late with us in casting off their foliage, and some time must be allowed for rest before lifting for forcing, or, at any rate, if lifted, the roots may remain outside for a time to rest. As a rule, there is nothing gained by placing things in heat for forcing before they have been got ready, and this resting by exposure is a part of the work. All vacant land should be trenched 2 feet or 3 feet deep and thrown up rough to let in the air to break it up and fertilise it. Those who leave their land covered with weeds during the winter lose a good deal in the way of fertility. This is the season to improve heavy land by adding sand, ashes, burnt earth, and street sweepings which contain a good deal of grit; but where the roads are repaired with granite the sweepings set hard and are not so suitable. This is not the season for using artificial manures, but basic-slag or anything slow of action may be used now. We have obtained good results from using basic-slag now and nitrate of soda in spring and early summer. Turnips fit for use keep well if pulled up and the bulbs covered with earth in a trench, leaving the tops outside. Turnip-rooted Calery may be kept in the same way. Parsley for winter use should be in a position to be easily covered. E. HORDAY.

THE COMING WEEK'S WORK.

Extracts from a Garden Diary.

November 10th.—Dahlias have been lifted, and when dried will be stowed away on the border inside a late Peach-house. This is made a general store-house for this and similar things which require to be kept cool, at the same time safe from frost. All the late Gladioli have been lifted, and when dried will be stored away. Some years ago I lost a lot of good bulbs by storing them in one of the garden sheds. They were killed by frost, and I am not likely to forget it.

November 11th.—We have a heap of dry Bracken laid up in an open shed ready for sheltering anything when frost comes. Planted more French Beans in pots in a warm-house. We have commenced pruning fruit-trees and bushes, and shall continue the work at every favourable opportunity till finished. We generally manage to get all the work done before Christmas, as there are so many things requiring attention when the days lengthen.

November 12th.—Gathered the last of the Apples and Pears. We have still a few Plums of Blue Imperatrice on a tree on a north wall. This is the latest variety we have. Some roots of early Rhubarb have been taken up, and will be placed in the Mushroom-house. Successional

roots will be started from time to time as required. Sowed Sweet Peas in pots. They will be kept quite cool. A row has been sown outside also.

November 13th.—All the tender plants from beds and borders have been lifted and potted. A good many of the old Geraniums have been potted up for spring propagation, as spring-struck plants, if helped on in heat, will be equal to autumn-struck stuff grown cool, and it is always possible to get enough cuttings in the early autumn. Arrears of work in planting fruit-trees, Roses, etc., are being brought up as fast as possible.

November 14th.—Moved a few bulbs of Narcissus, Tulips, and Hyacinths to a warm house to hasten blooming. All hardy shrubs intended for forcing have been placed under cover. The pots of Peaches standing outside have been surrounded with dry Bracken to protect from frost. Early-sown Fancies are now very bright in the beds and borders. We have a good stock of the new double Arsbis from cuttings rooted during the autumn, and shall plant it in masses.

November 15th.—Rearranged conservatory to make room in a prominent position for groups of Tree-Carnations and Zonal Geraniums, which are now very bright. Duplicates of choice alpine plants, of which some are kept in pots, have been plunged in ashes in frames, though the lights will not be put on till bad weather comes. Stirred the soil among the Violets now flowering in frames, and gave liquid-manure.

LAW AND CUSTOM.

The Wild Birds' Protection Acts (A. R. A. G.).—On Sept. 19th you went out intending to catch some birds with bird lime, and you took with you a tame linnet and a goldfinch that you and your family have had for eight years. As you were commencing operations a policeman came up and took possession of the goldfinch and took it away with him. You have three times requested its return, but the man says he cannot return it without the consent of his sergeant. The police have requested the occupier of the land to take proceedings against you, but he has refused, saying you were doing no harm. At the most he could only have sued you in the county court for damages for trespass, and he acted wisely in refusing. You committed no offence against the criminal law, and the policeman had no power to take possession of the goldfinch. My advice is that you sue the policeman in the county court for damages and for the recovery of the goldfinch, and if you employ a solicitor you are certain to win your case.—K. C. T.

A gardener's tenancy.—I am a jobbing gardener, and attended to a garden and greenhouse for a gentleman who died some six years ago. At his death I took the house, garden, and greenhouse of his executors at the weekly rent of 6s. They knew that I took it for the purpose of growing plants for my trade, but they charged me nothing for a few plants then in the greenhouse, although I offered to pay for them. I am now thinking of giving up the place, and I have eight or ten times as many plants in the greenhouse as there were when I took it. How many plants must I leave?—H. H.

[You are not bound to leave any plants—those that remained when you entered were given to you by the executors. If the place is still owned by the executors, it might be an act of courtesy on your part to leave just as many as you found on entry, but if the place now belongs to other owners, there is no reason why you should leave any plants in the greenhouse.—K. C. T.]

Income tax.—I bought a small part of a field of freehold land, and converted this part into a garden and built a greenhouse upon it. Subsequently, on removing from the neighbourhood, I put up a notice that the plot was for sale, and, out of pure charity, allowed a poor man to use it rent free, on the condition that he gave it up at any time on demand. I have paid the rates on the land, and now am, for the first time for 15 years, required to pay income tax upon it. Can the demand for income tax be enforced?—NORTHWOOD.

[No, you derive no income from the land, so you cannot be taxed for it. Perhaps your tenant might be compelled to pay income tax if his income from all sources amounted to £16 a year, but it seems clear you cannot be taxed. Neither can you be compelled to pay rates, although your tenant could be compelled to pay them, as his occupation is clearly beneficial. It would have been better if you

better if you had stated in what form tax is demanded and under what schedule. My answer refers to landlord's property tax, schedule A of the income tax. If you had any money borrowed on the place, and you paid interest on the loan, you might be taxed on the mortgage interest, but you could deduct the tax when you paid the interest.—K. C. T.]

BIRDS.

Death of young Canary (J. Simmons).—The lungs of this very prettily-marked bird were in a state of inflammation, but the immediate cause of death was disease of the liver, which was quite incapable of discharging its natural functions in the system, the wonder being that the sufferer should have survived so long as it did. This trouble was, in all probability, brought about, as in the case of numberless young birds, through an extensive use of egg-food. It is all-important to get young Canaries on to seed, and to discontinue the egg-food with as little delay as possible, for if allowed the opportunity they are pretty certain to take more of this than is good for them, and soon become surfeited and contract disease of the liver and bowels. As to the lung trouble, it may have been caused through the bird having taken cold at the moulting period—this frequently happens through lack of care in keeping young Canaries free from draughts and changes of temperature at this critical period. As soon as a Canary shows signs of moulting, the cage should be carefully covered up from draughts, especially at night, while a few Groats and a little Maw-seed may be added to the usual diet. A piece of chalk or old mortar should be supplied, and a rusty nail put in the drinking water to furnish a mild tonic. Linned is very useful in helping birds over their moult, and toast-water is sometimes given.—S. S. G.

CORRESPONDENCE.

QUESTIONS.—Queries and answers are inserted in GARDENING free of charge if correspondents follow these rules: All communications should be clearly and concisely written on one side of the paper only, and addressed to the Editor of GARDENING, 17, Finsbury-street, Holborn, London, E.C. Letters on business should be sent to the PUBLISHER. The name and address of the sender are required in addition to any designation he may desire to be used in the paper. When more than one query is sent, each should be on a separate piece of paper, and not more than three queries should be sent at a time. Correspondents should bear in mind that, as GARDENING has to be sent to press some time in advance of date, queries cannot always be replied to in the terms immediately following the receipt of their communication. We do not reply to queries by post.

Naming fruit.—Readers who desire our help in naming fruit should bear in mind that several specimens in different stages of colour and size of the same kind greatly assist in its determination. We have received from several correspondents single specimens of fruits for naming, these in many cases being unripe and otherwise poor. The difference between varieties of fruits are, in many cases, so trifling that it is not clear that specimens of each kind should be sent. We can undertake to name only four varieties at a time, and these only when the above directions are observed.

PLANTS AND FLOWERS.

Early Chrysanthemums (Ignorant).—Procure the Chrysanthemums and Begonias in the spring, and plant in the open air in May. We have given lists of the best varieties in several of our late issues, which you had better consult before purchasing the plants in the coming spring.

Rose Reve d'Or as a standard (Inquirer).—This Rose makes a glorious head, but is rather shy in flowering. We think more suitable yellow or orange-coloured kinds for standards are W. A. Richardson, Bouquet d'Or, Billard and Barré, or Mme. Pierre Cochet.

Rambler Rose with injured growths (A. M. B.).—The brown appearance of the growths is caused by the wind, as we can detect no disease. It looks as though the growths had awayed about, and thus became chafed. Upon slightly scraping the bark we found it quite green beneath. You need not be alarmed at the appearance of the shoots, as they will quickly lose this.

Rose Reve d'Or not flowering (M. A. F.).—For the first two or three years this Rose is a very shy bloomer. When the growths become well matured and produce good stout laterals, these latter produce other laterals, which furnish the blossom. To assist the blossoming, the branches should be spread out as much as practicable, bending them to the right or left, and even partly bowing them over. This variety, being so very vigorous, should be planted where it has plenty of space. If used on a trellis, train the growths something after the style of an espalier fruit-tree.

Rose Marechal Niel in greenhouse (Thorp).—Apparently your plant is ripening off, and as *Natura* has now no further use for the old foliage, it is falling. The somewhat unnatural and dry dead wood you see in the greenhouse at this season of the year has nothing to do with

the plant rather earlier than usual, but it is better that the growths become really hard than go on growing late in the fall, as this Rose will frequently do. You must keep the plant somewhat dry at the root for a time. As soon as you see the green buds commence to swell rather prominently, you can water occasionally; but one good soaking would be better than dribble.

Roses on south wall not flowering (Mrs. Hudson, East End).—The Roses on south wall that have not made much growth this season must be allowed to remain as they are at present. Prune back growths in spring to good plump eyes to encourage new wood, although you may not obtain much blossom again next summer, you will ultimately do so if the young wood retained each year, merely cutting out that which is worn out or dead. The W. A. Richardson will blossom well next year if you bend over its growths slightly and do not prune them beyond removing extreme points. The Lady of the Valley should receive an annual top-dressing in autumn of short manure or rich soil, and the *Carmine* border would benefit by a like application.

Protecting Roses in winter (Miss Hobbs, East End).—Nothing is better for this purpose than to draw this around each plant to a depth of 5 inches or 6 inches, but should the bushes be planted close together you had better bring some soil from another part of the garden. Tea and other half-hardy Roses so protected would come through the winter safely. Probably the tops would be cut down to the soil, but beneath this soil wood would be sound. Some dry straw or Bracken fern will do good if stuck in among the branches in addition to the soil, but this should be removed during mild weather. Standard Teas should either be lifted and heeled in under a north wall and protected by boards or hurdles in winter, or their heads stuffed with dry straw or Bracken fern.

Evergreen Roses for arch (Perryle).—The proposed arrangement would answer well. Good kinds of Roses for the purpose and that retain their foliage in winter would be: *Felicité-Perpetue*, white; *Louisa*, *Rambler*, red; *Aglia*, yellowish-white; and *Rosa* (of *de Wurtemberg*, red. The best *Hoseynockles* will be *L. brachypoda* and *L. flexuosa*. *Clematis Flammula* and *C. F. rubra* are both very lovely and fragrant. They blossom in July and August. An early kind would be *montana*, and a later sort, *C. graveolens*. You could introduce a plant, perhaps, of *C. Jackmanii* in order to obtain some blue colour, and a good white companion is *C. Henryi*. The two last do not furnish the amount of growth of the other kinds, although their flowers are not so showy.

Datura (*Rosie*).—Planted out in a bed or border of any kind, and allowed plenty of room and abundance of moisture, this will soon form a handsome specimen. The long and white flowers are freely produced, and the seeds often continue in bloom till the end of the year. After moulting, the plant should be pruned at each year, below the pruning is done the plant should be allowed to get dry at the roots, otherwise bleeding will follow. If the tree well in the open air during the summer, choosing either a sheltered position with plenty of sunshine, planted out towards the end of May in a rather light, friable soil. If lifted in the autumn, potted and placed in a temperature-house, the plants will do good service for many years at the flower garden.

Covering delicate plants (C. M. F.).—We are not aware that protectors are made other than in the places where they are used. Some are made of galvanised iron wire, having four straight pieces as legs of 18 in. in the soil, and side and width pieces fastened together with smaller wire. At a height convenient, the wire is first turned outward slightly, and returned, say, 18 in. In this way a groove is formed, into which the plant may be placed. It is not a convenient method, but the only one seeing that the plants that require covering may vary in height and size. For all ordinary purposes, a sheet of glass fixed on the rock cases and kept in position by another sheet, does equally well—all that is required is that wet shall be thrown off, and a free current of air secured to the plant.

Description of flowers (Decon).—So far as we know, there is no book dealing with the description of florists' flowers, such as you name. At the same time, every florist issuing a catalogue usually appends descriptions to such groups as are catalogued by him. In certain instances, where a large group is specialised, the descriptions may also be a feature. All the large nurserymen issue such catalogues, and, as the varieties are frequently changing, these are, of necessity, more up-to-date than any work could possibly be. Houghton's book on Carnations and florists' flowers may assist you, but is confined to one or two groups only. Any florist supplying you with plants should be able, if called upon, to give you descriptions of the same.

Bougainvillea Sandieriana (Northfield).—The charming form of *B. glabra* succeeds well in the greenhouse, especially when clothing the light, sunny side of some similar position. It may also be grown in light tubs by tying the long, flexible shoots to a few sticks, and the specimens are sometimes grown in this way. Its proper treatment is in the open air, but during the winter, when in a cool-house, it will not be till the autumn is fairly advanced, the plants should be kept somewhat dry at the root, in order to thoroughly ripen the wood. With this in the way the plants will, on the return of spring, with the increased temperature and additional moisture, break out freely and produce their flowering shoots in great profusion. The flowers of this *Bougainvillea* are small, but insignificant, but are surrounded by large bright-coloured bracts, which supply the place of blossoms. They commence to develop soon after midsummer, and continue till the autumn. The more they are exposed to light and sunshine, the brighter will be the colour of the bracts.

TREE AND SHRUBS.

Plants under Beech-trees (E. Rra Harcourt).—You appear to possess a rather difficult piece of ground to deal with satisfactorily. The *Daphne* and the *Edy* of the Valley are among it least likely to succeed. You may, however, try such things as the *Candytuft* (*Persea* kind), the *St. John's Wort* or *Hypocistis*, the *London Pride* (which may be planted in several varieties), the *Arabis*, and *Suberbia* in several varieties. Of bulbous plants you could now plant *Scilla*, *Cyclamen*, *Flower of the Sun*, *Fritillaria*, and the *Lily*: will do

biennials, such things as Bugloss, Evening Primrose, Wallflowers, Snapdragon, and the like. To these may be added the Arnerias, Thymus lanuginosus, Helleborus, Cerastium, Achillea (dwarf kinds), Alyssum matrifida, Vinca, Saponaria, Draba, Aconite in variety, and many more. If sufficiently open and warm, the alpine plants and Dianthus generally should do quite well.

Rhododendron, moving (C. E. A.).—If prepared for lifting, the plant should move quite well. Dig a trench round about it at not nearer than 2 feet from its stem, and in such a way that all root fibres outside this limit are cut clean away; then return the soil, and wait till April next, before moving the plant. In April dig out the same trench, and, when the plant is loosened, work off some of the top or surface soil with hand-fork or similar thing. This will facilitate the moving and prevent the ball breaking in half. Finally, before lifting it out, work a mat about the ball of roots, and so take it to its fresh quarters. The hole should be in readiness, and should be so guarded that the plant when in position rests in a slight saucer-shaped hole to admit of thorough watering for a few weeks. Indeed, upon this and overhead moisture, together with a good peaty mixture or very sandy loam about the old ball, will the plant depend for its fresh start. We take it the plant has been some years in its present position.

FRUIT.

Wood Leopard-moth (Gross-patch).—Your fruit-trees have been attacked by the Wood Leopard-moth, which often is very destructive to fruit-trees. The moth lays its eggs on the bark, and the caterpillars eat their way into the tree. If the caterpillar cannot be reached with a wire, paraffin-oil or tar should be injected into the hole, which should then be closed with a pellet of clay.

Pruning Vines (S. Newton).—Cut off all the laterals, and do not depend on any of them. Some growers advise leaving long spurs at pruning time, but this is a mistake. It is far better to cut the laterals off to the first eye, and then, when the vine starts into growth, it is easy to rub off the weaker one. For the health of the vine, as well as for the neater appearance, it is always best to prune so as to have the spurs close home. You should cut down to the bottom one or two of the Rose bushes that have flowered, and in this way encourage the plant to break from the bottom.

VEGETABLES.

The Celery-maggot (Morag).—Your Celery endive has been attacked by the Celery-maggot, which, you examine the leaves, you will find between the leaves. If not speedily destroyed, it will entirely destroy the plants, especially if you have allowed them to become dry at the roots. Broadcast sprinklings of soot and lime will often prevent the flies depositing their eggs in the leaves, but when once the maggot has developed, nothing but rigid hand-picking will eradicate it, as it conceals itself between the tissues of the leaves, and defies all ordinary insecticides. You ought to go over your plants very carefully, and, wherever seen, destroy the maggot. Sometimes one picking over suffices, but if a second attack occurs this must be repeated.

Making a kitchen garden (Belvidere Road, Leicester).—As your ground is at present in a very rough, uneven state, you should have it well levelled and cleaned from weeds, then either deeply dug or, better still, trenched, carefully keeping the lower soil well down in the process. If in doing that you could mix with the clay a few laches thickness of street-sweepings, which contain a good deal of grit and horse-droppings, it would do great good. Feeling that, give a heavy dressing of soot. If you wish to make paths, throw out the soil after they have been properly marked out, 8 inches or 9 inches deep, fill in with clinkers or rubble, and on that gravel or ashes. Some kind of edging, such as boards or tiles, should be put down beside each path. Get fruit-trees planted so soon as the ground has been made ready and the paths set out. Plant preferably in rows across the garden, rather than beside the paths. Before sowing vegetable seeds in the spring, have the ground well forked over and first dressed with fish-guano or gritty manure, such as is earlier advised. Clay soil needs plenty of grit and fibre put into it.

SHORT REPLIES.

H. O.—Are you quite sure you have got the *Ampelopsis Velutina*? We have never heard of it notching to a wall. **Blanc.**—We do not think you will succeed. We saw the same thing tried just lately, and the cultivation was a failure. **Constant Reader.**—Vine-leaves to hand, but it is quite impossible, so late in the season, to form any opinion as to the trouble. **T. K.**—From the specimen leaf sent we should imagine that there is something wrong with the roots, they being either too dry or the drainage of the particular plant is at fault. **F. S.**—Try putting your Dahlia-tubers in sand in a box. When you lift them stand them upside down for a few hours, so that the water can drain out of them. **H. E. B.**—Seeing your plant is healthy and, as you say, doing well, you should leave it as it is. It will do no good to move it into a smaller pot. **Miss Hodson.**—Apply to T. Smith, Newry. **H. L. H.**—We know of no book dealing with the distillation of flowers. **W. K.**—You ought to have repeated the query when you sent the information as to the part of the country you write from. **T. Kennet Ware.**—You cannot do better than plant some of the many forms of *Helleborus*, *Michaelmas Daisies*, and *Lilliums* in variety. See article, "Lilies at Kew," in last week's issue. **Winter.**—Consult our advertisement columns. **Claude Flight.**—Yes, you can use horn-shavings, mixed with the soil, for pot plants, such as *Geraniums*, *Fuchsias*, *Cinerarias*, etc., and you will find it answer well. **Kelly.**—You ought to sow such things in boxes, pans, or pots, prick them out, and then, when strong enough, put them into their permanent quarters. Leave your fruit-trees as they are. Very likely your Plum-tree wants root-pruning. The curling of the Peach-tree leaves was owing to insect pests. You ought to have washed it well with some insecticide. **S. C. R.**—If you cannot obtain peat, use the next best material—viz., leaf-soil, which must be well mixed with the soil you have. Azaleas of all kinds must have peat to do well. **Floral Designs.**—The only book we know of is "Table Decoration," by Low, but we learn that it is out of

print. You may, however, be able to find a second-hand copy on a bookstall. We know of no book dealing with the other matters you inquire about. **T. H. M.**—Your *Chrysanthemums* have evidently been attacked by mildew, and you have applied the only remedy. **J. Britter.**—Roses will do no good in such soil as you send, and you will have to prepare stonions for them. **E. B.**—Scrape it off with a hoe; or you might try one of the many weed-killers now advertised. **E. O'H.**—You had better defer moving your Hare-foot Fern until the spring, when the growth is on the move. **T. N.**—Write to the Director of the Royal Gardens, Kew.

NAMES OF PLANTS AND FRUITS.

Names of plants.—**L. Nash.**—*Eccecarposacchar.*—*Northleigh.*—Double Ragged Robin (*Lychnia Pilocuculi fl. pl.*)—**G. W., Beckenharn.**—1, Oval-leaved Privet (*Ligustrum ovalifolium*); 2, Evidently a Forsythia, but must see flowers; 3, *Andromeda japonica*; 4, *Cypripedium Lawsoniae erecta viridis.*—**C. Pyke.**—1, The Scarlet-fruited Thorn (*Crataegus coccinea*), from North America. **J. E. Hodson.**—We cannot name florists' flowers. **Miss Noel Walker.**—Quite impossible to say from such a small scrap as you send. **R. H. S.**—1, *Aster Novo-Anglie W. Bowman*; 2, *A. Mima*. Cacheux, as far as we can judge from your specimen; 3, *Aster Novo-Anglie pulchellus.* **A. G. L.**—*Helleborus rigidus* Miss Mellish. **Marie.**—*Clematis Viticella rubra.* **Robert Canterbury.**—Bird Cherry (*Prunus Padus*). **J. K.**—Viper's Bugloss (*Echium vulgare*). **G. C.**—1, *Sedum Ewersi*; 2, *Lonicera aureo-reticulata*; 3, *Elaeagnus pungens.* **B. Brown.**—*Lycesterie formosa.*

Names of fruits.—**S. C.**—1, Sandringham; 2, Leatherroot Russet; 3, Flinders' Pippin; 4, Scarlet Nonpareil. **L. A. S.**—Apple Egremont Russet. **W. Campbell.**—Pears: Smooth, Doyenné Boussoch; Rough, Josephine de Malines. **J. C. L., Aberystwyth.**—1, Small's Admirable; 2, Lady's Finger; 3, D'Arcy Spice; 4, Yorkshire Beauty. **H. J. Graham, Dorset.**—1, Pimston Duchess; 2, Durondeau; 3, Beurre Clairgeau; 4, Calabasse. **H. Camden.**—No numbers affixed. **Stafford.**—Specimen insufficient; not, however, Louise Bonne de Jersey. **T. M., Yetminster.**—Evidently a local sort, not recognised. **John Stroud.**—Apples: 1, Newton Wonder; 2, Eymcr. Pears: 1, Brown Beurré; 2, Doyenné du Cornice.

Catalogues received.—Dammann and Co., Naples, Italy. **General Price List.**—Ernst Benary, Erfurt. **List of Novelties, etc.**—Amos Perry, Hardy Plant Farm, Winsborough Hill, London, N.—*Catalogue of Hardy Border and Rock Plants.*

The Prize Winners this week are: 1, Mrs. H. Peters, Bill Hill, Wokingham, for part of group of *Lilium giganteum*; 2, Mr. John Bolam, Bilton House, Lesbury, for *Jargonella Pear-tree* on house.

NOW IS THE TIME TO PLANT

Kelway's LOVELY NEW Pæonies

The most delightful product of the XXth Century. The flower for the NEW CENTURY. No Garden is complete without them. Most decorative as a Cut Flower, and gloriously beautiful in Beds and Borders. They are Hardy as the Dock, and charming in the infinite number of tints in flower and foliage, and should be planted now to secure flowers next season.

THE FASHIONABLE FLOWER.

KELWAY'S PÆONIES were ADMIRÉD and SPECIALLY PRAISED by Her late Gracious Majesty **QUEEN VICTORIA**, and also by Her Majesty **QUEEN ALEXANDRA**.

DOUBLE OR SINGLE-FLOWERED AS DESIRED. STRONG PLANTS ONLY. ALL ARE NAMED.

- Collection A, 18/- per doz. (100 for £6 6s.).—Purple, purple-crimson, cherry-red, rose, and lilac-rose colours are included in equal proportions.
- Collection B, 24/- per doz. (50 for £4 4s.).—Purple, purple crimson, crimson, cherry-red, deep amethyst, rich rose, rose, lilac-rose, rose-pink, and peach in equal proportions are included, and shades of white in less proportion.
- Collection C, 30/- per doz. (50 for £5 5s.).—The above colours, with the addition of maroon-crimson, faint blush, delicate cream and white, and sorts with fragrance are selected.
- Collection D, 42/- per doz. (50 for £7 7s.).—The most fragrant sorts, purest whites, and most delicate combinations of creamy-yellow, and white and blush, are added to the brightest of the above colours, and purple and lilac tints omitted.
- Collect on E, 60/- per doz.—Grandest novelties of the finest form and most delicate enchanting colours.

CARRIAGE PAID WITH CHEQUE FOR ORDER IF THIS PAPER BE MENTIONED.

KELWAY & SON, The Royal Horticulturists, **LANGPORT, SOMERSET.**
148 GOLD AND SILVER MEDALS—LONDON, PARIS, CHICAGO, ETC.

GARDEN & PLANT PHOTOGRAPHS, 1902.

The Editor of GARDENING ILLUSTRATED announces Photographic Competition for the season of 1902.

Class 1.—SMALL GARDENS.—A prize of FIVE GUINEAS and a SECOND PRIZE of THREE GUINEAS for the best ten photographs or sketches of picturesque small gardens, including town and villa gardens, rectory, farmhouse, or cottage gardens.

Class 2.—FLOWERS AND SHRUBS OF THE OPEN AIR.—A prize of FIVE GUINEAS and a SECOND PRIZE of THREE GUINEAS to the sender of the best series of not less than twelve photographs of the above. These may include wild plants or bushes, or any plant, flower, or shrub grown in the open air, including also half hardy plants put out for the summer, and either single specimens or groups, or the effects resulting therefrom, in beds or borders. Shoots also of rare or beautiful plants photographed in the house may be included in this class.

Class 3.—INDOOR FLOWERS AND PLANTS.—A prize of FIVE GUINEAS and a SECOND PRIZE of THREE GUINEAS for the best series of indoor plants—greenhouse, stove plants, Orchids, or any other plant out of the open air—either single shoots, plants, or specimens, or the effects resulting from good grouping or other arrangements of such plants separately or in association with others. Ferns or groups of Ferns in houses may be included in this class.

Class 4.—BEST GARDEN FRUITS AND VEGETABLES.—A prize of FIVE GUINEAS and a SECOND PRIZE of TWO GUINEAS for not less than twelve photographs of the best kinds of garden fruits and vegetables, Grapes, Peaches, Apples, Pears, Plums, Cherries, or any other fruit grown in Britain, to be shown singly or on the branches. Overcrowding, as in dishes at shows, should be avoided. The aim should be to show well the form of each kind, and as far as may be life-size. The object of this is to get good representations of the best garden fruits and vegetables under the old names, though we do not want to exclude real novelties when they are such.

Class 5.—GENERAL SUBJECTS.—A prize of FIVE GUINEAS will be awarded for the best twelve photographs of any garden subject not included in the previous classes, such as water gardens, waterside effects, rock gardens, picturesque effects in gardens, vases, cut flowers, table decorations, and pretty garden structures.

All competitors not winning a prize will for each photograph chosen receive the sum of half a guinea. In order to give ample time to prepare good photographs the competition will be kept open until November 29th, 1902.

WHAT TO AVOID.—Cut flowers or plants should not be arranged in vases with patterns on them. Backgrounds should be plain, so as not to come into competition with flowers. Figures of men or women, barrows, watering-pots, rakes, hoes, rollers, and other implements, iron railings, wire, or iron supports of any kind, labels, and all like objects should be omitted from these photographs. Dwarf flowers are ineffective when taken directly from above. The camera should be brought low down for such. All photographs should be mounted singly, and not several on a card. They should not be mounted on cards with black backs, and the photographs should not be less in size than 5 inches by 4 inches. The subjects should not be overcrowded. The following are the rules to be observed by all competitors:—

FIRST.—The photographs may be of objects in the possession of either the sender or others; but the source whence they are obtained must be stated, and none the copyright of which is open to question must be sent. There is no limit as to number, and no fee to pay. The Editor is to have the right of engraving and publishing any of the chosen photographs. The photographs may be printed on any good paper that shows the subjects clearly. Platinotypes and bromides should not be sent, but those on albumenized and printing out papers are preferred for engraving. All photographs should be properly toned.

SECOND.—The name and address of the sender, together with the name and description of the objects shown, should be plainly written in ink on the back of each photograph. Care should be taken to avoid the ink being seen on the face of the photograph. This is very important.

THIRD.—All communications relating to the competition must be addressed to the Editor, 17, FURNIVAL-STREET, EOLBORN, LONDON, E.C., and the class for which the photographs are intended should be marked on the parcel, which must also be labelled "Photographic Competition." Unsuccessful competitors who wish their photographs returned must enclose sufficient postage stamps for this purpose.

HARDY PLANTS A SPECIALITY.

My Collection of Herbaceous Plants contains many of the finest varieties, not only of the newer introductions, but also of the old favourites, which are so seldom seen nowadays, but which served to make the English gardens beautiful years ago. For those who require a succession of flowers the herbaceous border is an absolute necessity, for by a judicious selection quantities of bloom may be had for at least nine months in the year, and often with very little attention the plants will improve annually. My plants are dug straight from the open ground, and so, being healthy and well established, are certain to produce best results. I make no charge for packing. All plants sent post free. Below are noted a few out of the many described in my Catalogue, which is sent post free on application.—N. LOWIS, The Perennial Nurseries, Levensdown, Bridgwater.

A CHILLEA PTARMICA FL. PL.—Produces quantities of double white flowers, splendid for wreath or bouquet making, height about 2 ft. 3 for 1s. 3d., post free. Centaurea macrocephala, 3m, 6d. Rustic-like flowers; succeeds anywhere, but prefers a damp position; height 3 to 4 ft. 4 for 1s. 3d., post free.—N. LOWIS, The Perennial Nurseries, Levensdown, Bridgwater.

COREOPSIS GRANDIFLORA.—This flower is indispensable when cut bloom is in request, producing as it does its brilliant yellow blooms in great profusion for weeks; height 3 to 4 ft.; 3 for 1s. post free. Chrysogonum virginianum, an uncommon plant from North America, golden-yellow, blooms in May; height 6 in. to 1 ft.; 3 for 1s. 3d.—N. LOWIS, The Perennial Nurseries, Levensdown, Bridgwater.

GALEGA OFFICINALIS (Goat's Rue).—A useful perennial of very rapid and strong growth, showing many racemes of mauve, pea-shaped flowers; 4 for 1s. 3d., post free. The white variety, same price.—N. LOWIS, The Perennial Nurseries, Levensdown, Bridgwater.

WHITE ROCKET is one of our most fragrant flowers. 6 for 1s. 4d., post free. Lavender Plants, particularly fine. 3 for 1s. 3d., post free. Gaillardia grandiflora, nice plants of this favourite flower. 4 for 1s. 3d., 3 for 2s. 3d., post free.—N. LOWIS, The Perennial Nurseries, Levensdown, Bridgwater.

LINARIA REPENS ALBA, one of the most easily cultivated flowers, and one which ought to be in every garden; produces numberless sprays of pearly white flowers. 3 for 1s. 4d., post free. Linum flavum.—This beautiful little yellow flax is worthy of more extensive culture; seldom grows more than a foot high. 3 for 1s. 3d., post free.—N. LOWIS, The Perennial Nurseries, Levensdown, Bridgwater.

ICELAND POPPIES, 2s. per doz. Polyanthus (splendid strain), 2s. 6d. per doz. Sweet Williams, 2s. 3d. per doz. Brompton Stocks, 20 for 1s. 3d. Canterbury Bells, 30 for 1s. 6d. Wallflowers; Golden King, 30 for 1s. 6d. Single, mixed (grand mixture), 30 for 1s.; Dwarf double, mixed, 30 for 1s. 6d. All above first-class stuff, no rubbish, and all post free.—N. LOWIS, The Perennial Nurseries, Levensdown, Bridgwater.

BULBS.

BEST AND CHEAPEST EVER OFFERED.
DAFFODIL COLLECTION.—1,100 fine bulbs, in 20 splendid varieties, £2; half, 7s.; quarters, 13s.
TULIP COLLECTION.—260 fine bulbs, in 10 splendid varieties, and 10 grand names, 21s.; half, 12s. 6d.; quarters, 7s.
HYACINTH COLLECTION.—100 fine bulbs, in 5 separate colours, double and single, 21s.; half, 12s. 6d.; quarters, 7s.
GENERAL COLLECTION.—Anemones, Daffodil, Dog's-tooth Violet, Jonquil, Montbretia, Snowdrop (50 each), and Crocus, Gladiolus (dwarf), Grape, Hyacinth, Spanish Iris, Ixia, Kamomecree (Persian and French), Sparaxis, Tritelesia (100 each), 1,200 bulbs, 21s.; half, 12s. 6d.; quarters, 7s.
Carriage and Packing Free.
 All kinds of Rare and Beautiful Plants at Popular Prices. *New List now ready.*

FRUIT.

LATE GRAPES.

The past season has been none too favourable for Grape growers. The spring was a fortnight late, and we did not have sufficient hot weather during the summer to make up for the loss of time. In houses where no fire has been used Black Hamburgs were only colouring in the last week of September, whereas last year I was cutting good ripe fruit at that time. In spite of the unfavourable summer, grapes have been, and are now, so plentiful in the London and provincial markets, that prices have reached a lower level than has hitherto been the case. Some years ago I ventured to predict that good English Grapes would be sold for one shilling per pound in Covent Garden Market. The prediction has been verified, for last winter really good Alicantes were disposed of in December at that price, and there does not appear to be any prospect of improvement this season. Whether these low prices will continue I cannot say, but when one takes into consideration the vast amount of glass that has been devoted to grape growing during the last ten years or so, there does not seem much prospect of Alicante and Gros Colman making from 1s. 6d. to 2s. 6d. per pound, as was the case several years ago. What can be expected when one man alone covers seven acres of land with vinerias? In all parts of the country big glass-houses, such as the past generation would never have dreamt of, have been, and are being, erected, and the greater portion of these are planted with Vines, crops of Tomatoes being taken from them until the Vines have covered the roof. A friend of mine, who had two houses, 376 feet long each by 25 feet wide, as now put up six more, each one 125 feet long by 25 feet wide. There can be no doubt that the production of late Grapes has been very profitable during the last twenty years, but the time when there was much money in grapes has passed, and he who now invests money in vinerias will have to be content with fair interest on his outlay.

The best paying Grape is undoubtedly the Muscat—that is to say, where the soil suits it well enough to allow the grower to annually take from the Vines a good weight of fruit. Those who have a soil naturally favourable will have no difficulty in keeping their Vines at a sufficiently high state of health to enable them to bear during the first twenty years of their life bunches running from 1 lb. to 3 lb. in weight. Unfortunately, all soils do not suit this Grape, and when this is the case the Vines quickly deteriorate, and the bunches come narrow-shouldered, do not always set well, and will take on that rich amber tint that recommends them to the salesman and fruiterer. Better far grow the Alicante or Gros Colman, and grow them well, than produce Muscats that are lacking in colour and flavour. The Muscat loves a loamy soil, not heavy, and well drained. It will do very well in lighter soils, but the grower

has to be very careful in the matter of cropping. If the Vines when they come into full bearing are allowed to carry all the bunches they form, they are sure to deteriorate. I have known more than one good house of Muscats to be quite ruined by incautious cropping, and in one case the Vines had to be rooted out.

Owing to its good keeping, heavy-cropping qualities, size, and appearance, Gros Colman has been so largely planted during the last few years that really good prices for fine samples seem to be a thing of the past. Some five years ago Gros Colman realised 30 per cent. to 50 per cent. more than Alicante—now there is very little difference, and this I know, that good Alicantes will make more than indifferently-grown Gros Colman. I fancy that some have made a mistake in planting so many of the Gros Colman, which, in soils naturally favourable, is a grand Grape, taking on a high colour, and forming bunches of from 2 lb. to 4 lb., with enormous berries. In some soils considerable difficulty is experienced in colouring this Grape, and badly-coloured Gros Colman is a drug in the market. The worst of it is that unless the berries take on their proper colour they will not keep well, so that the grower has to get rid of them long before he can expect to see any rise in the price. I once knew of a case where the greater portion of a large house had to be sold at 4d. per lb. The house was not so well heated as it should have been, the season was rather bad, so that the berries generally were of a dull red at the close of the growing season. The grower was glad to sell the whole lot at Christmas for less than 6d. per lb. This Grape should be started about the latter end of February in the north of England, and not later than the middle of March in the warmer counties, so that the berries get thoroughly ripened. Without the necessary amount of saccharine juice they will not keep through the dulllest months of the year. The worst of Gros Colman is that it has, in an even greater degree than other varieties, a tendency to push its roots into the subsoil. This is very marked in the case of light soils, but may in a measure be counteracted by judicious root-pruning every four or five years. Both this Grape and the Alicante may be subjected to root pruning, but one must be very careful with respect to the Muscat, as this Grape does not make roots so freely as the black kinds do. J. C. B.

THE PLANTING SEASON.

It is a decided gain to get young trees from the nurseries and plant them properly before the winter fairly sets in. Before the late heavy rains, the ground, both in the open and in particular against walls, was much too dry for transplanting operations to be carried out without risk of failure, and it is doubtful if the borders sheltered by walls are yet well moistened. Before, therefore, trees are moved the border should be examined and water given freely if the soil is found at all dry, while if the soil that surrounds the roots after planting is done is also dry, or even on the dry side, a good soaking ought to be given before the surface is levelled over and mulched with

straw litter. These waterings help to settle the soil well about the roots, doing this more effectually and better in every way than it can be done by tramping. Especially should water be given when trees are moved while yet some of the leaves are green. Allowance must always be made for a settlement of the newly-moved soil, and it should also be remembered that there is a tendency for the soil of a border to increase in depth farthest away from a walk. If, therefore, the trees are not planted rather high, the collars being kept well above the ordinary ground level, there is every likelihood of their becoming too deeply buried, not thriving or proving so profitable as desirable accordingly. More particularly is high planting advisable in the case of trees on cold, heavy soils. The roots are only too liable to strike downwards into cold or poor subsoils; whereas they render the best service when kept active on or near to the surface. A rich compost should not be given to quite young trees, as this may promote a too rank, unfruitful growth. On the other hand, when fairly large trees are moved from strong ground, many roots being unavoidably, and in some cases recklessly damaged, undue exposure to drying winds also doing much injury, then they must not be given a poor soil, or they are not likely to grow satisfactorily next season. Sometimes the trees received have been already badly started in the nurseries, and must be grown out of it before they prove profitable. If newly-purchased trees cannot be properly planted soon after arriving, then ought they to be laid in thinly by the heels, taking good care to surround the roots with good fine soil in a moist state. Laying whole bundles of them in together will not do, as in this case the bulk of the roots does not come into contact with the soil.

VINES FAILING.

Will you kindly inform me through the medium of your paper, GARDENING ILLUSTRATED, what should be done with my Grape Vines? For the past two or three years the fruit has been getting poorer and smaller in size, especially this season's crop, which has been a fairly large one, but the Grapes very irregular in size and only about half on a bunch reaching maturity. I have two houses, one containing six Vines about twenty years old, the other three about 10 years, black Grapes, all, I believe, of one sort. Some are rooted inside in deep bed, and others rooted outside. The gardener has of late taken to keep other potted plants in the same houses at different periods of the year. Would such action be detrimental to the health of the Vines, also skinning the rods annually? The houses are well ventilated and, of course, heated. I shall be greatly obliged if you will advise me whether you think these Vines can be brought round, and in what way? Or if not, how, when, and with what kinds I should replace the old ones.—H. V. R.

[The cause of the partial failure of your Vines is due to their faulty root action. Vines have a natural tendency to ramble away from the border, no matter how good this may be, unless their treatment is of the very best. There are many Vine borders that are given an annual complement of manure dressings and water but which contain very few active roots, and these are at such a depth that they derive no benefit from surface tillage. Yours present to us a similar state, and we should not be surprised if you found on examination that the roots had gone deeply into the subsoil, and

probably right away from the border altogether. You do not intimate a desire to have more kinds of Grapes, but as a means of succession it is well to employ more variety. The better course would be to root out the oldest Vines and replant, after having made an entirely new border. This can be done piecemeal—that is to say, a yard wide would suffice for two years, and an additional yard could be added in alternate years until the space was filled. Good turfy, calcareous loam is that best suited to your purpose, and it is advisable when making a border to do it well, because once made it lasts a good many years. Lime-rubble is a valuable addition to the loam, and so are bones, $\frac{1}{2}$ inch or larger. Beyond this and a little artificial Vine manure, nothing should be required at present. Some employ loose manure, but it is not usually necessary. If your younger Vines are Black Hamburgs, then we should plant the other house with Alicante, Appley Towers, and Gros Colman. A Vine of Black Hamburg may be added, and if a white Grape is desired, choose Foster's Seedling. Omit Gros Colman if the house is not started by March 1, or is not continuously heated. The other Vines should be overhauled and a search made for roots by cutting out a trench along the outer edge and bringing any roots found to the surface, first liberating them with a fork. The sooner this is done the better, because the autumn-formed roots help the Vines to become re-established. In this case much good would be done by the employment of new soil to incorporate with the old, as also would some fresh horse-droppings and a light dressing of a special Vine manure. Young Vines may be planted in March. Although vineries are better kept free from plants, there is not so much harm done by them as some suppose to Vines or border. Peeling of the rods in winter is necessary only if they are infested with insect pests, such as mealy-bug or red-spider. If these abound, then it is necessary to remove the old or outer bark, so as to be able more easily to deal with insects. We have no sympathy with the wholesale peeling some gardeners practice when it is done simply out of custom, and for no other reason or purpose. It is an unnatural practice, but one rendered necessary when the rods are infested with mealy-bug.]

FINE FRUIT FROM YOUNG TREES.

In no department of the garden has more change been noticeable during the past few years than in that connected with the cultivation of hardy fruits. In my young days, if anyone planted Pears it was said he was planting for his heirs. Thanks to greater knowledge of grafting on stocks suited for producing fruitful trees, we now get the very finest fruit from trees that only a few years back would have been hardly out of the trainer's hands. One of the first things in the way of pruning, in my early days, was to cut newly planted trees quite close back to the graft, so that several years elapsed before there was any bearing wood at all. Now the work of preparing fruitful trees is much better understood, and it is quite a common thing in the autumn to see young trees in the nursery rows carrying a good crop of fruit, quite small trees being usually as well set with fruit buds as the older bearing trees are. If you wish trees that will carry the finest fruits, you must constantly replace any that begin to fail with young trees. I have not got a fruit-tree of any kind that is much over twenty years old, and the majority are under that age. Every year at this time I go over them, mark any that are not satisfactory, and grub them out. After a thorough preparation of the site with new soil, manure, etc., I shift a good strong tree that wants more space into its place, and then there is no waiting for a crop. In fact, maiden or one-year-old, or one-year-trained trees, as received from the nurseries, should be planted out for at least two years before they are finally placed in position. If they are removed with care early in the autumn, they will, in all probability, set their fruit just as well, and produce far finer samples than old-established trees. By getting the trees so early into a fruitful state the pruning is reduced to a minimum, as the strength of the tree goes to

forming fruit-buds, and there is very little useless wood to remove. The best antidote to gross, unfruitful wood is a very firm and not over-matured soil at first, varying the pruning with the varieties. If it grows strongly, leave the annual shoots double the length of those of a kind that produces little growth, and do not aim at uniformity of growth, for almost every variety has its distinctive character. Root-pruning is doubtless necessary sometimes, and will, if skilfully done, change an over-luxuriant tree into a very fruitful one. Gooseberries and Currants are often left too long in one place, for the finest berries are produced by young, vigorous trees. JAMES GROOM, Gosport.

APPLE SANDRINGHAM.

This solid, white-fleshed Apple is valuable for cooking from November to March, its good flavour and juicy, tender flesh making it when fully ripe a very refreshing dessert fruit when juicy Apples are scarce. It bears freely, trees on the Crab cropping well in about five years from grafting. The growth is upright and fairly strong, though not gross. On the Paradise tree the fruits are very large, and as an orchard tree the fruit is above the average size. It is of handsome shape, the fruits mostly highly coloured, deep purple-red on the exposed side and green, changing to yellow, at the base

A good late Apple—Sandringham.

and on the sheltered side. A striking characteristic is the heavy bloom with which the fruits are covered, and it is also thickly speckled all over with tiny dots.

NOTES AND REPLIES.

Strawberry St. Joseph rotting.—I have sent samples of St. Joseph Strawberry, showing decayed state of fruit, and shall be obliged if you can tell me the easiest remedy? The plants have fruited continuously in open ground from June, and ripened perfectly until about three weeks ago. Latterly, however, a large number of the berries on each plant have decayed. I have still a quantity of fruit, ripe and unripe, most of it at present healthy, but some showing signs of turning bad. As I find this the most serviceable variety to grow, fruiting, as it does, for six months in succession, I shall be much obliged for your advice.—Q. K.

[Due, no doubt, to the weather. You ought to lift the fruit off the ground on to slates or bricks.]

Apricot-tree not blooming.—I bought from a good nursery four years ago an Apricot-tree. It is growing very strongly, but has not flowered. What treatment do you advise? It has made tremendous growth this year, and is on a wooden fence facing north.—K. G.

[Your Apricot-tree is evidently growing in too rich soil. Dig a trench at about 3 feet from the stem, remove some of the soil about the roots, and mix with it a liberal quantity of lime rubble, first cutting back any strong roots there may be, and then treading the soil replaced firmly in the trench. An absence of lime and soil rich in humus are certain to set up a vigorous growth, which will produce neither flowers nor fruit.]

Defoliating Vines.—I have read with some interest an article in your last issue on

“Defoliating Vines,” by J. Crook. I think we can let light into our vineries by shortening the shoots back to three eyes without injuring the Vines in any way. J. Crook says it is no uncommon thing to go into vineries in September and then see Vines stripped of their foliage. He does not mention if these Vines have been hard forced, or have been heavily fruited. I think that would be more the cause than shortening the shoots when growth has almost ceased.

Seedling Peaches.—I have two Peach-trees two years old which my children have grown from stones. They are about 4 feet high and very healthy. Should they be pruned now or in spring, and will they fruit without budding, and when? One faces west and the other east.—K. G.

[We presume your trees have grown where the stones were originally planted, and have had no training. Assuming this to be so, and that they have grown upward on a single stem, they may be cut down to within a foot of the soil in February next. By cutting them down thus, several lateral growths, that in time may be trained to the wall in the form of an open fan, will be formed. Seedlings are slow to come into bearing, but there is no need to bud them in order to procure fruit. We have recently seen growing against a wall several seedling Peaches and Nectarines, that are from three to four years old, which this year bore just a few fruits—some would have a dozen, others not more than two or three. We find the trees flower freely enough, but for some reason they do not set their fruits like trees worked on other stocks. This, however, may be a failing only when so young. They grow freely enough, and in some cases too strongly, and need much attention in spring and summer in dealing with the superfluous shoots and lateral growth. There is an interest attached to seedling trees almost unknown to the recognised named varieties. The chance seedling is not likely to develop into anything highly superior; still, if there is average merit it is worth retaining, especially if there is an interest in its history. The prospective value of seedling fruit-trees depends on their spring and summer treatment, and we might say they are not so easily manipulated as are worked trees.]

Plum Grand Duke.—For cooking, Grand Duke ought, owing to its freedom of cropping, good size, colour and lateness in ripening, to gain favour. With me it has not failed to crop for several years; indeed, not since it first came into bearing, and in this year of dearth it seems peculiarly marked in its freedom of bearing. My tree, just in the height of its vigour, has been this year literally roped with handsome fruits, providing a supply until mid-October, a time it must be admitted when Plums are serviceable in the kitchen. From the lateness of its ripening, it need scarcely be said that the shelter of a wall is advantageous, because high winds or a severe autumn frost soon spell ruin to unprotected Plums.—W. S.

Planting fruit-trees on espaliers.—I am having a fence 84 feet long made between the kitchen and Rose garden, and should be much obliged if you could advise me as to the best kind of fruit-tree for it, whether Apples, Peas, or Cherry? The fence faces south-east, and a very strong north-east wind blows from the back of it. The soil is fairly loamy, Roses doing very well with me.—Abolton, Nottingham.

[The term “espalier” is used in relation to trees only, and not to the fence on which trained, which is, as we understand, 84 feet long. The height is not stated, but for espaliers trees a good height is 5 feet, the wires or wood laths being 10 inches apart, the lowest being just so far from the ground. In the length named you should be able to plant eight trees, thus allowing intervals of 10½ feet between them. That is, however, none too much, but it generally suffices. As you say the trees would look south-east—a very good aspect—and that you have behind strong, cold, north-west winds, you should, if possible, plant as a break some sort of hedge, say, 4 feet behind the trellis, which could grow up and be kept hard trimmed. Unless you have some such break we fear the exceedingly cold draughts between the fruit-tree branches, which would at times prevail, would injure the trees, as the hardest would

inevitably suffer if exposed to cold currents of air. If you cannot plant a hedge, could you fix weather-boards to the back of your trellis fence, as those would not occupy space? This matter should have serious attention. Your soil seems to be admirably suited for fruit-trees, but most likely the addition to it of some wood-ashes, old lime-rubbish, and soot would be better for the trees than at first adding any animal manure. You should plant, of eating Apples: King of the Pippins and Cox's Orange Pippin. Of cooking Apples: Lord Grosvenor and Lord Derby. Of Pears: Louise Bonne and Cantillac, a stewing Pear; and of Plums: Rivers' Early, Victoria, and Monarch. It may be too cold for Cherries, especially as, if not warm enough, the shoots do not ripen, and blight is rapidly created. Dig the ground deeply dug 4 feet wide in front of the trellis, and plant at once, but not too deeply. Leave the trees to settle for a month before you tie them to the trellis, or even prune them.]

Apple Blenheim Orange.—The excellent illustration (page 437) correctly represents good specimens of this popular Apple, and "T." does well to warn amateurs who have got a limited space against growing this, for unless it can get plenty of room to extend it is useless. Unfortunately, this is not the only good Apple that is useless for small gardens, and intending planters should consult reliable works on fruit culture before selecting any kind, however good it may be, if it has not been proved to succeed in their own locality, and above all to be fruitful in a small state. I have fruiting trees of a very large number of kinds of Apples, but should never recommend for small gardens Blenheim Orange, Peasgood's Nonsuch, or Bramley's Seedling, simply because they will not fruit in a size suitable to amateurs' gardens. I am well aware how handsome they look in collections of fruit, but each needs special culture to get the fine fruit to perfection, and the ordinary amateur wants a tree well set with fruit buds, to begin with, and that will grow into a good shaped bush and yield a regular crop every year. If the compilers of fruit catalogues would tell their customers what sorts to avoid, they would do them a greater service than telling them what to plant. Really good free-cropping Apples that succeed with reasonable care are too numerous, and the good varieties that have never had a name would fill large volumes. I frequently see loads of Apples that come to this locality from the New Forest orchards, the majority of the trees being chance seedlings or very old and well-known varieties.—J. Groom, Gosport.

Transplanting fruit-trees.—There is ample evidence that summer shoots on fruit-trees, even on walls, will ripen rather later than usual. But the lifting or replanting of fruit-trees need not be delayed in consequence. It will, in many cases, do trees good if they now receive some root check so as to cause the flow of the sap to materially cease, the wood harden, and the leaves to fall. It is so much better that operation should take place under the influence of ripening, rather than be forced by frost. Then it is a very good plan to have leaves on trees when they are transplanted, because these exercise some useful influence in promoting quick root-action, and that is of material value in helping to establish trees early in the winter. The sooner the planting is done also, the warmer is the soil, and warmth at the roots also helps to promote quick rooting. The old practice of running a Birch-broom over wall-trees to cause the leaves to fall is not desirable in ordinary seasons, and certainly not in the case of trees it is proposed to transplant. But this autumn some assistance in removing the leaves on permanent trees may be desirable.—A. D.

TREES AND SHRUBS.

LAURUSTINUS (VIBURNUM TINUS).

This beautiful and fragrant evergreen thrives over a large area of Great Britain and Ireland, especially near the sea and on warm and gravelly soil, though occasionally injured by severe frost even in the districts south of London. In sunny districts it flowers freely, and we noted some fine bushes in full bloom on November 1 in a garden near Ealing, the soil being gravelly and well drained. It will keep up a succession of bloom until March.

There are several varieties of Laurustinus, the best being the form here figured:

V. T. LUCIDUM, in which the leaves are larger, shining, and almost smooth on both sides, the flower-trusses also much larger. This is found to be less hardy than the type, and on this account should always have a sheltered and sunny spot. Another variety is

V. T. HIRTUM, in which the leaves and branches are hairy, while in the case of

V. T. PURPUREUM the leaves are suffused with a dull purple tinge.

NOTES AND REPLIES.

Raising Gorse.—I am about to lay out and plant a site in the country. The soil is light and the spot somewhat wild, and I wish to preserve its character. I am therefore thinking of planting Gorse hedges, and shall feel greatly obliged if you will kindly give me the following information in your next issue: 1, Best mode to propagate Gorse, either cuttings or seeds? 2, Seed is certainly the best, sowing this in the spring, but if you have any Gorse in your district, you will probably find young plants in their vicinity which can be transplanted? 3, How to plant—in one or more rows, and distance apart? (The great point is to sow or plant thickly.) 4, Is any special preparation of the ground required? (None whatever.) 5, About how many years would it take to get up a hedge, say, 4 feet high? (You will have good growth the first year and good hedges in two or three years.) Site is now Grass land, about 18 inches of light, friable loam and then sandy loam. Gorse grows splendidly on the site now. (You have the best possible condition for Gorse to grow.)—SUFFOLK.

Evergreen shrubs.—I should be very pleased if you would tell me the twelve best evergreen shrubs—compact varieties are preferred—that will make good specimens? Do you think Cryptomeria japonica is hardy enough to stand the winter outside here?—A. Y. L., Leicester.

[Without knowing the purpose for which your overgreens are needed, and whether you wish Conifers to be included, it is rather a difficult matter to advise. If your soil is suit-

Viburnum Tinus lucidum. From a photograph by Mrs. Heath, Dunley, Bovey Tracey.

The Laurustinus is also very useful for forcing into bloom early in the year. Anyone who has a warm house may employ the Laurustinus to great advantage, as the plants may be stood in a light shed or cold-frame, and introduced to heat as required. Where there are draughty corridors to decorate these forced plants will be found very useful, as they last a long time in flower, and do not suffer when exposed to changes of temperature. It would be well to grow some of these always in pots or tubs, as, apart from the enjoyment to be derived from them early in the year, they serve as a guarantee against exceptionally severe winters, when the outdoor plants are due to cut down. The trusses of bloom, too, are very useful for cutting, a single truss with a background of its own foliage, a Geranium leaf, or a sprig of Maidenhair Fern, being much esteemed as a buttonhole. It is well, after the flowers have fully opened, to move the plants to a cooler structure, where they will remain in good condition for several weeks. Little plants lifted from the borders, potted in spring, and attended to during the summer, giving them a sunny position to thoroughly ripen the growth, come in well the following season for

able, Rhododendrons must be included in the list, but if it is necessary to omit them the following may be relied on to all succeed in ordinary soil. Aucubas, both green and variegated, and if you plant a male and female plant together you will have a crop of their bright-coloured berries; Berberis Darwinii, 6 feet to 8 feet high, orange flowers, May; B. stenophylla, 6 feet, golden-yellow blossoms, May; B. Aquifolium, 4 feet, rich yellow flowers, March and April; Eleagnus pungens variegata, 5 feet to 6 feet, a pretty variegated-leaved shrub; Euonymus japonicus, and its variegated varieties, 3 feet to 6 feet; Hollies (Ilex) of sorts, including green and variegated, while Ilex crenata is a pretty little Japanese evergreen, with tiny deep green leaves; Olearia Haastii, a dense rounded bush, 3 feet to 4 feet high, clothed with deep green Box-like leaves, and bearing in July little white starry blossoms; Osmanthus illicifolius, a Holly-like shrub, whose deep green leaves are tinged with purple; Skimmia Foremanni, a delightful shrub 2 feet to 3 feet high, that bears its bright red berries in great profusion. As you speak of the Cryptomeria, we think perhaps that your question refers to Conifers, in which case the following should suit you: Cupressus

Lawsoniana compacta, C. Lawsoniana gracilis, C. Lawsoniana nana, Prumnopitys elegans, Retinospora filifera, R. obtusa compacta, R. plumosa, R. plumosa aurea, R. squarrosa, Taxus adpressa, Thuja orientalis aurea, and Thujopsis dolabreta. You need have no doubt that Cryptomeria japonica is quite hardy enough to stand the winter outside with you.]

PLANTS AND FLOWERS.

ROSES.

MY EXPERIENCE WITH ROSE CUTTINGS.

As I have gained all my knowledge of gardening from your paper and descriptions given therein by amateurs I contribute my experience for others' benefit. Last year, in the end of October, I put in twelve cuttings of the Crimson Rambler Rose and six of Gloire de Dijon. All the former have grown into good plants with from three to six good shoots, two of which are over 3 feet in length. Only two of the latter have grown, but one of them is a specimen, several growths, and one very strong, 3 feet 6 inches in length. Why I am surprised at my success is that I took no trouble with the cuttings. I simply cut up some growths of the year into about 12 inches long, forced the spade into the ordinary garden soil, pushed the cuttings well down, and stamped my foot on each side. Possibly this is the correct way; at any rate, it has resulted in success. I have to-day (Oct. 30)—just twelve months since putting them in—potted them into 8-inch pots, so as to be able to plant them at any time. I shall bury the pots in ashes, and leave them out in the open ready for transplanting into permanent positions. I have also been very fortunate in budding. In July and August of last year I budded twelve Briers, ten of which bloomed this year—viz., two Gloire de Dijon, one W. A. Richardson, one Baroness Rothschild, three Mrs. Paul, two Dupuy Jamain, and one John Stuart Mill. I have also budded ten more this year, and they have all taken, including two Crimson Rambler, which I tried for experiment. I think anyone who loves Roses, and has only a small garden, might beautify his house, if even he only grew two or three of the Ramblers on the walls, by putting in a cutting or two now against the side of the house; by next year he may have some 2 feet or 3 feet of growth, and in two years a good space may be covered with some bloom (some of my cuttings before mentioned bloomed this year, but I pinched them off). My friends may say: "This is all very well on paper, but where is anyone to get the cuttings to start with?" Well, at this time of year, anyone who has Roses of the Rambler kind has always superfluous shoots, which must be cut away, or, at any rate, could be dispensed with. These he would be glad to give to anyone who might ask for them.

Llandaff, S. Wales.

C. PERRY.

CHINA ROSES.

Among the China and Hybrid China Roses are to be found some of the most constant and free-flowering of all the Roses, as they are seldom out of bloom from the commencement of the early summer months until the autumn—in fact, they never cease flowering altogether until overtaken by severe weather. This constant and prolonged habit of flowering renders these Roses peculiarly suitable for growing in masses in large beds or borders or for covering banks. They are mostly free or vigorous growers, and quickly cover a good space. They are as hardy as the Hybrid Teas, and require but a moderate amount of pruning each spring. The same amount of protection afforded the class of Rose just alluded to, answers for the Chinas, whether it takes the form of loose litter, Bracken, or drawing the soil up to a certain height round the stems or cluster of stems composing each separate bush. Like Tea Roses and their hybrids, Chinas like generous treatment—such as a good dressing of well-rotted manure placed on the surface as a mulch in late autumn, and dug in after the pruning is performed in the spring. Artificial manure afforded during the growing period is

also beneficial, and this may take the form of equal parts of fine bone-meal and dried blood, with a small proportion of muriate of potash added. When mixed, just enough of this may be sprinkled on the surface of the soil to colour it, and it should at once be hoed or raked in, or, what is better, watered home with diluted sewage. Such a dressing as described may be administered twice, and in the case of poor soils thrice, during the season with advantage.

Some of the China Roses vie with Tea varieties in the exquisite colouring of their blossoms, more particularly when in the bud state, for they are then charming, and never fail to arrest attention. Queen Mab, Lauretta Messimy, and Mme. Eugene Resal are perhaps the most beautiful of all the Chinas, the first having apricot-coloured flowers shaded with rose, the next may be described as rose shaded with yellow, and the last-mentioned is variable—sometimes salmon shaded with pink and yellow, and at others coppery-red suffused with rose. Duke of York has beautiful rosy-pink flowers, which are produced in great profusion. In Ducher we have a creamy-white variety, forming a nice contrast to the rich velvety-crimson flowers of Cramoisie-Supérieure, which is too well known to need further description. Archduke Charles has rose-coloured blossoms suffused with crimson, and then there is the common or Blush Chine, better known perhaps under its old title of the Monthly Rose. The next two to be named, Mrs. Bosanquet and Armosa, are classed as Hybrid Bourbons, but they associate so well with the Chinas, and produce such large quantities of blossoms withal, that this must be my apology for including them in my list. Mrs. Bosanquet has beautiful delicate flesh-coloured flowers, and Armosa, lilac-pink, is a grand variety for massing. Aurore, a yellow flower suffused with salmon, is exceedingly pretty, as is Jean Bach Sisley, which yields large silvery rose-coloured blossoms. A. W.

NOTES AND REPLIES.

The Seven Sisters Rose.—This, one of our old Roses, bearing clusters of white blossoms, is of vigorous growth, and soon covers a wall or trellis. I have one over a lattice fence, and in the past summer it has been much admired. All the pruning it gets is a shortening of the ends of the strongest shoots each year, and this treatment seems to suit it. Where other Roses would die this old variety thrives, and if the blossoms are not fine as some count them, they make a good show.—W. F. D.

Perpetual-flowering Roses for exposed situation.—Will you kindly give me names of China and Perpetual-flowering Roses suitable for planting in an exposed bed with a bleak, north aspect? Will Laurette Messimy be too tender a Rose?—Scribble.

[Laurette Messimy would be a very good kind and quite hardy enough for the situation. If earthed up about the base in winter one need have no fear of such Roses succeeding. A few other good kinds are the common Monthly, Jean Bach Sisley, Armosa or Hermosa, Mrs. Bosanquet, Augustino Guinoisseau, La France, Caroline Testout, Camoens, Grace Darling, Viscountess Folkestone, Mme. Pernet Ducher, Mme. Abel Chatanay, Ferdinand Jemin, Mme. Wagram, and Gruss an Teplitz.]

Pruning Rose Soleil d'Or.—Kindly let me know if the new Rose Soleil d'Or should be pruned same as a H.P.—D. W.

[This may be pruned at the proper time somewhat in the same manner as one would a vigorous-growing H.P.—that is to say, leave its new wood about 7 inches or 8 inches in length, and any lateral growths cut back to three or four eyes. I believe it will prove to be a useful pillar Rose, and perhaps in this form or as a hedge Rose we shall see it at its best, but it also makes a fine standard. The flower is rather too double to expand well in a wet season, so that we may not see it in its full glory until a hot summer occurs again. Under glass every flower opens well. The fragrance is pleasing, and has gained this Rose many admirers this season.—ROSA.]

Rose W. A. Richardson.—I saw quite recently in a cemetery some excellent plants of this favourite Rose employed as miniature arches over graves, and the bending of the shoots compelled a freer blossoming than sometimes is the case with this variety. These

arches were covered with dozens of the orange-coloured buds, and beautiful they looked in the autumn days. W. A. Richardson is especially good for a chalky subsoil, and blooms more freely where the roots cannot penetrate too deeply. It is not necessary to peg down the growths, as by pruning moderately they blossom very freely. I think this Rose should always be on the Brier stock in some form or other.—ROSA.

Rose Crimson Perpetual.—This very old Rose, known as Lee's Perpetual, also as Rose du Roi, has been flowering very freely this autumn. Although when compared with our modern Hybrid Perpetuals the variety would scarcely be tolerated to-day, yet when sent out by Lee early last century it was in much demand, as, of course, then autumn Roses were very few in number. The form of the flowers is cupped, and the colour is a bright crimson. A very pretty striped form of this Rose was sent out some few years ago under the name of Panache de Lyon. The flowers were as prettily marked as a Carnation and sweet scented. Can anyone say why the group to which this Rose belongs is called R. Portlandica or Portland Rose? I cannot find any authority for this, and there may be others interested in the matter. If old Roses drop out of cultivation it is often helpful in knowing their history, in order to assist the raiser and hybridiser in their work.—ROSA.

CHRYSANTHEMUMS.

NATURALLY-GROWN CHRYSANTHEMUMS.

The term "naturally grown" is usually given to Chrysanthemums that are made to develop a bushy form and which are not subjected to the severe disbudding necessary if flowers of exhibition quality are desired. It is, however, a misnomer, for, strictly speaking, a naturally-grown plant would have neither its shoot-stopped nor any of its flower-buds removed, both of which operations are nearly always practised. In growing Chrysanthemums of what may be termed the exhibition type, the sole object in view is to obtain flowers at once of the largest size and as near as possible of the form that has been set up by the florist as an ideal one. In the cultivation of that class with which the present observations deal, the aim is entirely different; it is, in a word, the beauty and effectiveness of the plant as a whole rather than those of the individual flower. In growing this class of plants it is of great importance that each should be clothed with foliage almost or quite to the base of its stems, and that whilst the shoots should be disposed and supported so as to secure sufficient symmetry of form, the stiff outlines and unwieldiness of the "specimen" plant of the exhibition should be as carefully avoided. With regard to the flowers themselves, the aim should be to obtain them large enough to show the true and distinctive character of the variety, and yet in sufficient number to fully furnish the plant, thus avoiding the wasteful process which accrues from restricting the energies of the plant to the production of two or three flowers.

It is questionable whether by encouraging so exclusively as exhibitions do the big flower and the conventional specimen plant, the true interests of horticulture are furthered as much as would be done by adopting a system of culture that requires as much real gardening skill to obtain the best results, and which, from an artistic standpoint at least, are infinitely more pleasing. The groups of plants seen at even our best shows, with their carefully sloped surfaces, look brilliant and gorgeous enough at the top; but to the inquisitive eye that searches below there is revealed a huddled mass of long stalks and pots (the latter not infrequently stood one above another), which is to the last degree unsightly. Looked at singly, such plants are hideous, and even when massed together in a formal sloping bank, which is the only arrangement they are presentable in, the few square yards of colour they give cannot be said to be an adequate return for all the expense and labour they have entailed during the previous twelve months.

OUTDOOR PLANTS.

HARDY CRINUMS.

In English gardens Crinumms are frequently grown in pots in hothouses, but so restricted they give one a poor idea of their value, hence it is encouraging to know that in the south of England and in Ireland they can be grown to great perfection in the open air. One of the best known is *C. capense* syn. *Amaryllis longifolia*, which grows from 2 feet to 3 feet high, flowering in the late summer, and bearing its large, funnel-shaped blooms in umbels of 10 or

A deep rich border between the buttresses of a wall suits them perfectly, or a warm corner near a heated greenhouse or plant stove. Dig a large hole and fill it up with good turfy loam, coarse sand, peat fibre, and leaf-mould, well mixed. Crude manure should never be used; but if some good bones can be added, these will prove of great assistance. Care must be taken when the border is low-lying or wet that the drainage is good, this being formed of 18 inches or a foot of rough stones or brick-rubble. When established and in fine growth abundance of water in the summer is necessary if the weather is dry. In very cold situations

obvious is that the plant must be in itself handsome and somewhat showy. The next, and one of the most important, is that it should remain a good while in flower. Plants that are in flower a few days only and then are done are of little use in the mixed border, unless their foliage is unusually handsome and persistent, in which case this is so valuable a quality that it may redeem the plant.

The choice of kinds being decided on, the way in which they are arranged then becomes the matter of chief importance. It seems a natural arrangement to use the creeping and short-growing plants in front and the next in

Crinum Powellii in Mr. Gumbleton's garden at Belgrove, Queenstown, Co. Cork.

15 on a stout stem. There are now several varieties in addition to *C. capense* which have proved quite hardy, these being *C. Moorei* and its variety *C. M. album* and *C. Powellii*, of which there is also a white form. *C. Powellii* is the result of a cross between *C. capense* and *C. Moorei*. Many seedlings were raised, all varying in colour from deep rose crimson in the bud to pure white. Practically speaking, there are three distinct forms of *C. Powellii*—viz., a dark rosy flower, a light rose form, and a pure white kind; each scape is from 2 feet to 4 feet in height and bears from seven to 15 flowers. If the clumps are doing well from five to 20 spikes are thrown up each season. Once well planted Crinumms are best left alone

a little heap of leaves should be placed over the bulbs, the tops of which should not be less than 8 inches below the surface.

THE MIXED BORDER BEAUTIFUL.

It is not altogether an easy matter to keep a mixed border well furnished throughout the flowery months of the year, and to avoid unsightly gaps, but there are ways of doing it, and even beginners should not be afraid of facing this fact, and of thinking out ways and contriving methods so as to have as few empty places as may be. There are some commonsense considerations that will be a guide to the choice of plants to use. The first and most

stature behind them, and the tall ones at the back. This is obviously a good general rule, but if not varied with judicious exceptions the result will be very monotonous. Now and then some of the tall backward groups should break forward. Think of the way in which the lateral spurs of a mountain chain descend into the valley or plain. They all do come down to the level, but in how varied and beautiful a way. Think of this and then think of the dull and ugly slope of a slate roof, and then think of your border and apply the lesson. Then try and get hold of some definite scheme of colouring, to get richness and brilliancy with dignity. It saves much trouble and puzzling at planting time to have a regular

scheme of simple progression of colour from end to end, so that if you have a yellow-flowered thing to plant you put it in the yellow place and so on. In no way can you get so much real power of colour, by which is meant strength, richness, and brilliancy, as by beginning very quietly at the ends of the border with cool-coloured bluish foliage and lowers of tender colouring, white, pale blue, and palest sulphur-yellow, and even with these, palest pink; beginning quite *piano*, then feeling the way to full, and from that to strong yellows; then by a gradual *crescendo* to rich orange, and from that to the *forte* and *fortissimo* of scarlets and strong blood-crimsons, and then again descending in the scale of strength to the pale and tender colouring.

In other parts of the garden you may have incidents of brilliant contrast, which are especially desirable in the case of strong blue flowers; but in the mixed border the way of having the rich and brilliant harmony approached by more delicate colouring can scarcely be improved upon, and so only can the vice of garish vulgarity be avoided.

Plants of the same colouring are intergrouped, so that the red group, whether early or late, is always a red group, and so on throughout. There are ways of filling gaps by training plants down to fill the spaces. For this use, Everlasting Peas, tall perennial Sunflowers, Rudbeckias, and Dahlias are especially accommodating.

Nothing is so destructive of good effect in the mixed border as the old unthinking mixed up way. Plants of the same kind, instead of being dotted at equal intervals, should be grouped together, each group dying away into the neighbouring group, or if there is only one plant of a kind there is no harm in its being one alone if only it is in its right place.

Of course there are other ways of arranging the details of a mixed border, and many devices that may be used to enhance its effect at the different seasons, but these suggestions will be a good basis of operation to anyone who is without experience and desires general instructions.—*The Gardener*.

THE OLD BLACK AND WHITE PINK.

AN old and valued correspondent of ours is looking for the above plant. Perhaps some of our readers in the north may be able to tell us where plants can be had. The following is the description of it:—

"The old 'Black and White' Pink that I am always looking for is like a single kind called Beauty, in double, not too double, not more than two more rows of petals, perhaps only one, as the dark blotch shows plainly. I have enquired for it in the papers over and over again, and many people have kindly sent blooms and plants, but the right thing has never come, except once from Scotland, a rather weak plant that I unfortunately lost. Nearly all that were sent were laced or somehow coloured at the edge. The real Black and White is nothing but black and white, a black blotch in the middle, so dark a red-black that it tells us black, and all the rest white, no lacing, no pink tinting anywhere. The whole habit of the plant is like that of the White Pink, the size of bloom and leafage almost identical, and it follows the White Pink in time of blooming."

PERENNIALS AND BULBS.

I SHOULD be much obliged if you would give in your most useful paper, GARDENING ILLUSTRATED, a list of perennial plants and bulbs which would give fairly continuous flowering during all months (except June and July), in a bed about 36 feet by 7 feet, running north and south, sheltered from all winds, but not getting much early morning or late evening sun. The bed runs along one of the walks, and is seen from one of the drawing-room windows, therefore I wish to keep it as bright as possible. The soil is limestone, but we have plenty of peat. Climate damp, west of Ireland. I shall be grateful for suggestions.—*AGATA C. CORLETON*.

[You will, perhaps, do well to arrange the bed in small groups, so that by a system of double planting quite a prolonged flowering season will result. For instance, as back row plants you may employ the following: Helianthus multiflorus plenus, H. m. Soleil d'Or, H. rigidus, H. tomentosus, Aster N.-Belgii Ariadne, A. N.-Angliae ruber, A. N.-A. Melpomene, A. N.-A. pulchellus, Kniphofia aloides, *Lilium candidum, *L. tigrinum, *L. t. Fortunei, *L. speciosum album, *L. crenatum,

*L. s. Melpomene. These range from 3½ feet to 4½ feet high. What we suggest is that of the herbaceous things you obtain three plants of each, and so form a small group, while the bulbous plants, which are marked thus *, may intersect the other groups and appear slightly in front of them. By planting three or six in a group having a ground area, say, of 12 inches or 18 inches a good show would result in autumn. By reason of its fine colour, we suggest two groups of the Aster N.-B. Ariadne. It is one of the best of the Michaelmas Daisies.

In the next line you could arrange such things as *Galtonia candicans, red and white Perennial Pea, Aster cordifolius Diana, A. c. Photograph, Rudbeckia purpurea, Pontstemon barbatus, Astilbe cordifolia, a selection of herbaceous Peonies, Gaillardia grandiflora, *Lilium Martagon, *L. dalmaticum, *L. Hansoni, *L. testaceum, Iris pallida dalmatica, I. Mme. Chereau, I. Dr. Bernice, I. Cheltes, Iris orientalis, Galega officinalis and G. o. alba, a few Delphiniums, such as conspicua, Landseer, Life-guardsmen, etc. These may be arranged similarly to the first, and 2½ feet from them in the row.

In a third row, or nearly a front row so far as the taller things are concerned, the following may appear: Aster Amellus, A. A. Riverslea, A. A. Distinction, A. levigatus, A. acris, Incarvillea Delavayi, Anthericum Liliustrum majus, Hemerocallis flava, H. Middendorfsiana, Rudbeckia Newmani, Primula lenticulata, P. d. Cashmeriana, P. rosea, P. Sioboldi in three varieties, Arnebia echinoides, Senecio Doronicum, Doronicum austriacum, Iris Mrs. Darwin, I. Victorine, I. Queen of May, I. stylosa, Megasea cordifolia purpurea, Phlox divaricata, and a set of hardy free-flowering Carnations, such as Old Glove, Ruby Castle, Uriah Pike, Alice Ayres, and others. The Carnations would be best several in a group, and the remainder as previously recommended. In the spaces between these plant such Daffodils as *Sir Watkin, *Barri conspicuus, *Emperor, *Horsfieldi, *ornatus, *poeticus fl. pl., *Stella, *Cynosure, *Frank Miles, and *maximus, with such other bulbous things as *Fritillaria Melegris and alba, *Crown Imperials, May-flowering *Tulips, *Spanish Irises in variety, and such-like. Then in the immediate front the bed may be carpeted with Aubrietias, Alpine Phloxes, and such things, or you may employ the Tufted Pansies in the same way, putting in good rooted cuttings all over the ground when the border is planted, and allowing them to form a general carpet to the entire bed. You could in this way plant in blocks of one colour, and with the new growth and the bulbs pushing through and flowering a very pretty effect would result. The front portion may be sprinkled with Snowdrops, Chionodoxa, Muscari, Snowflake, Anemones, and so forth, which would provide an ever-changing picture. Some very showy midsummer flowers are omitted—those for July, etc.—as you request. Bulbs are marked *.]

NOTES AND REPLIES.

Rudbeckia pinnata.—For a garden where the soil is poor and few things will thrive, Rudbeckia pinnata would suit. It grows in almost any situation, and for a couple of months one may depend upon the yellow blossoms, which are useful for cutting in early autumn. For a back-row border in town gardens I can recommend it, and it is at this season when it can be propagated by division of the roots.—*W. F.*

Border facing east.—May I trouble you to give me a list of herbaceous plants suitable for a border looking due east, about 6 feet deep and with a brick wall 8 feet high at the back? The border gets next to no sun.—*A. W. L.*

[Any of the species of Spirea, of Astilbe, Japanese Anemones, Kniphofias, Michaelmas Daisies, Day Lilies, Lenten and Christmas Roses, Peonies, quite a large array of the Flag Irises, such Primulas as P. Sieboldi, P. rosea, P. cashmeriana, Oriental Poppies, Perennial Pea, Montbretias, Helianthus, single and double Pyrethrams, Gaillardias, and, indeed, many other plants of the showy class. Quite a large number of the good hardy plants, as Stenactis speciosa, Harpaliums, and others above named, are not fastidious in the least, and in their day the majority of

sunlight is so great that their flowering is assured in almost any aspect you may select. The only difference is one of time in opening. Alstromerias, Hyacinthus candicans, such bulbous things as Crown Imperials, Fritillaria Melegris, Daffodils, May-flowering Tulips, Colchicums, and Crocus species, may all be expected to thrive, provided a good bed of fairly rich soil is at command. Lilium candidum, L. Martagon, L. testaceum, L. pinnatum, L. Harrisii, L. chalcodonicum, L. croceum, L. tigrinum, etc., may also be planted.]

The Burning Bush (Dictamnus Fraxinella).—One of the best known of old time garden plants is the Dictamnus, and seen to advantage often in country gardens, where, as with many, it is left alone. Indeed, one of the reasons why some fail to succeed with it is because of its being disturbed unnecessarily. Like Crinum, Peonies, and one or two more plants one could mention, the Dittany, to call it by its familiar name, should be planted in good deep soil and left alone. A border with the red and white forms in bloom in July is attractive, and all who wish to add this old-fashioned subject should secure plants as getting them in during open weather. It is one of the few plants that needs no support of any kind.—*W. F.*

Single Pyrethrams.—I grow many of the single sorts of Pyrethrams, mainly on account of their being more useful for cutting, to say nothing of their delicate colour. Perhaps this is one reason why of late years more of the single varieties have been grown. A dealer told me that where double sorts were once asked, now the singles are sought after, and, doubtless, the qualities named are answerable for their popularity. As June flowers, Pyrethrams are useful, but many put off until too late procuring them. Now is the best time to plant in open weather, and amongst singles the following are charming: Warrior, carmine-purple; Juno, rose; Aladdin, pure white; Jubilee, crimson; Duke of Connaught, carmine; Mrs. Bruce Findlay, deep rose; Nellie Goodman, rose carmine; Elsie Gertrude, pale flesh; Carmen Sylva, blush-white.—*TOWNSEND*.

A fasciated stem of Tropaeolum tuberosum.—I send you an extraordinary growth of Tropaeolum tuberosum. You will see that the flattened stem is fully 2½ inches wide, other stems have the same growth. The stems begin to flatten almost from the ground. The plant has not produced a single bloom. Is it probable that the root bulbs, if it has formed any, will be liable to the same defect?—*T. B. W. S.*

[No, it will not affect the roots in any way.]

Wallflowers.—I have three large boxes of Wallflowers, all with two and three leaves and 1½ inches high. How must I proceed with these to get them to flower next March or May?—*E. T. ORR*.

[No method of cultivation will make of these seedlings good flowering plants by the time stated. The plants are obviously a result of too late sowing, or the seeds have not vegetated quickly. All you can do now is to winter the plants in a frame or light, giving them more root room by planting out; otherwise, if the plants become hido-bound they may refuse to move at all briskly. It is quite likely that seeds sown now or to the end of the year will make as good or better plants if grown or without check, which is the most important item of all for any quick-growing annuals or biennials.]

Thalicttrum.—I have a box of Thalicttrum (marest) The seedlings are well up, and doing well if it was not for the two top leaves of the seedlings being eaten or dropping right off and only leaving stem. I have killed several woodlice lately. Would they be the cause? The same thing is happening to a box of Pyrethrum aureum and a box of Camassia. Kindly advise me what to do?—*E. T. ORR*.

[The woodlice may be responsible for the damage to the Pansies and Pyrethrams, but the above-named loses its leaves each year. It is the nature of any true herbaceous plant. The woodlice may be easily trapped in the evening by laying slices of Potatoes about. Meanwhile, elevate the boxes of young plants over a pan of water. Place a large saucer of water, with a flower-pot in it upside down, and on this stand the box of seedling plants. In this way the seedlings are safe, and the pest may be trapped at will.]

RAMONDIA (ROSETTE MULLEIN).

An interesting Pyrenean plant, with leaves in rosettes close to the ground, the flowers purple-violet in colour, with orange yellow centre, 1 inch to 1 1/2 inches across, on stems 2 inches to 6 inches

things that much dislikes removal, and should be planted where it can remain without disturbance, and where it can enjoy plenty of sun, a free circulation of air, and ample room to extend. Given these conditions, a small plant will develop in the course of three years

cask first, then adding the sulphate. Then get a rosed watering-can, and apply the mixture to the lawn over a space of 1 1/2 square yards. Apply it as soon as made. It should also be made with soft, or rain water, avoiding, if possible, that in which there is any lime. This may be done at any time during the year. When the Moss turns black the sulphate is known to be acting. If the solution is too weak, the Moss will only turn red, and another application is necessary. Moss, as a rule, indicates poorness of soil, and it is well after the Moss is destroyed to apply a good top-dressing of loamy soil, manure, and wood-ashes. Another way is to rake the Mossy parts well over with an iron rake, so as to clear off as much of the Moss as possible. If the ground is poor, give a dressing of good soil and sow in the spring some Grass seed, taking care not to use that from a hay loft.

Christmas Roses.—The scarcity of flowers in the open air in the depth of winter is responsible for the blooms of the Helleborus being so greatly valued. During a mild winter flowers may be gathered freely, but during periods of frost and snow blooms that would otherwise be pure are marred. It is, under these circumstances, well to remember in planting that the most sheltered quarter the garden affords should be set apart for them, a place where, if the weather prove unfavourable, it will be an easy matter to place over the bed a frame with one or two lights. So treated, it will be an easy matter in the worst of weather to gather blooms pure and clean. Christmas Roses may be grown in most gardens, provided they are given a deep, well-drained soil, and when once planted it is not advisable to disturb them too frequently. A good friable loam, into which has been worked some cow-manure, is the best compost for them; but I have seen them blooming freely when planted in ordinary garden soil when the drainage has been right. The latter point with regard to the Helleborus is often overlooked, and I am convinced that many causes of failure with them are due solely to this and to removing the plants too frequently. Although the white-flowering sorts

The Rosette Mullein (*Ramondia pyrenaica*) in the rock garden at York. From a photograph by Mr. Elliott.

long, in spring and early summer. There has been a good deal of writing about its cultivation, but it is really not difficult; growing in cool peat borders, on the lower ledges of the rock-garden, or in moist chinks. It is found in the valleys of the Pyrenees, on the face of steep and rather shady rocks. There is a rare white variety which does well in borders of American shrubs in peat soil. Other varieties are *R. Heldreichi*, *R. serbica*, and *R. serbica* var. *Natalia*, the last two found in Serbia, and which will be found described in our issue of Nov. 6, 1901, p. 484.

***Lychnis vespertina* fl. pl.**—Although this has been in cultivation a good many years, it is by no means common. This is probably due to the fact that it is not so easily increased as hardy flowers generally. No seeds are produced, and the root-stock increases so slowly that propagation by division can scarcely be reckoned on. A certain measure of success attends propagation from cuttings. If the young shoots that push from the crown in spring are taken off at the base when about 2 inches long, and inserted round the sides of 2 1/2-inch pots, keeping them in a cold-frame, close and shaded, a certain proportion will make roots. For a light, poor, porous soil I know of few better things than this *Lychnis*. It bears periods of hot, dry weather remarkably well, producing with freedom its pure double white *Gardenia*-like blooms all through the hottest months of the year. It is one of those

into a fine specimen a yard or more across, and which will carry in the course of the summer some hundreds of blooms.—J. C. B.

Hardy annuals.—I planted a bed with about twenty kinds of hardy annuals and hardy perennials about the middle of September. Wallflowers, Candytuft, Chrysanthemum (hardy annual), Virginian Stock, Calliopsis, and Prince's Feather are well up, but the others are not up yet. Will they all survive the winter? I have a cool conservatory.—E. T. OPIE.

[It is quite possible the seeds of the hardy perennials will not vegetate before spring, and that some of the annuals will succumb to the first severe frost. Virginian Stock, for example, or again, the Chrysanthemums, particularly if these be of the *C. tricolor* strain, would not endure frost. We hardly see your motive in this matter. Some few hardy annuals may be made to flower earlier by autumn sowing, but of those named the only ones likely to survive are Wallflowers, Candytuft, and Prince's Feather. The others may survive if transferred to cold-frame, but any heated structure would be bad. A few seeds sown in January in a pot, and transferred bodily to where to flower, would provide a far more reliable as well as early display. Indeed, we are surprised this last method does not find greater favour, the trouble being so very slight.]

Moss in lawn (*B. G. F. and Jocko*).—Get some sulphate of iron, and mix it in the proportion of 1 lb. of sulphate to 2 gallons of water. The solution should be made in a wooden cask, putting the plain water into the

Ramondia pyrenaica alba.

are mostly in demand—notably *H. niger* and *H. angustifolius*—*H. colchicus* (red) and *H. maximus* (tinged pink) should not be forgotten. They are best increased by division, an operation which should be performed in July. —WOODBASTWICK

ZONAL GERANIUMS IN WINTER.

For winter blooming strike the cuttings in March in heat in small pots singly. The best position for the cuttings is on a board placed over the hot-water pipes in a rather warm house. Select robust shoots which have been grown in heat. In a fortnight the cuttings will be rooted, and there ought to be no failure. Shift into 3½-inch pots, and grow on a shelf near the glass in an intermediate house, and when the plants have fairly started growth after repotting rub out the terminal buds. By June the plants will be ready for 5-inch pots, and when the roots have reached the sides of the pots place outside on a coal-ash bed and remove all flower-buds till September. Young plants produce the finest trusses, and the above method is, in my opinion, the best for obtaining really fine trusses. For earlier blooming I have frequently taken autumn-struck plants, and grown them on into 5-inch pots and let them bloom in spring, as these things have to be looked at from a commercial point of view. By the end of June the plants will be outside ripening, and shortly afterwards they are cut down and the cuttings inserted. These cuttings are potted off as soon as rooted, or they may be struck in a bed outside and potted up as soon as rooted and shifted on into 4-inch pots, in which pots they will be in flower on a shelf near the glass from Christmas onwards. The old plants that have been cut down in June will break strongly if left in the sunshine outside and not over-watered, and will flower very freely on a shelf near the glass till Christmas if required, and if shifted into 6-inch pots will form very large specimens for the conservatory, or will be very useful for producing cuttings for stock. There is a demand for these bright, broad-petalled flowers, especially when produced by plants of sturdy habit. This sturdy habit is mainly a matter of cultivation. The soil should consist of the best yellow loam two-thirds and one-third leaf-mould or very old cow or stable-manure, with enough sharp sand to make it open and sweet. There is some advantage in mixing a little soot or charcoal dust with the soil, as there is less danger of overwatering when the plants are making roots freely. Firm potting is very essential, and for winter-flowering the plants should have been ripened outside and the pots must be well filled with healthy roots. Weak liquid-manure may be given when the plants are approaching the flowering stage and have filled the pots with roots. The best winter temperature for these plants when in bloom is about 50 degs. at night; a degree or two either way is not important. The position should be a light one near the glass, and the atmosphere of the house should be reasonably dry, or, at any rate, not saturated. Ventilate freely on fine days, and give water only when the plants are dry. Watering is an important matter, especially if the drainage of the pots has been carelessly done. We have a large collection, and are continually adding thereto and weeding out those which have been superseded. The following is a selection from our collection, and some others equally good might be added: King of Purples, Edith Strachan, Ian McLaren, salmon; Chaucer, cerise; Mark Twain, carmine on white ground; Andrew Lang, Sir H. Irving, Pink Domino, Jerome K. Jerome, reddish orange; Heric, crimson-scarlet; Launce, rosy-pink, white blotches on upper petals; Snowdrop, Lord Idlesloy, Lancelot, Lady Reed, Athlete, Mrs. Miller, Magnificent, H. Cannell, Sunbeam, Duchess of Marlborough, King of Crimson, Bluebeard, Ruddyard Kipling, dark crimson-purple; Olivia, cerise; Sir Percival, white; and Duchess of Buckingham, rose. The above are all singles. We find the doubles, with the exception of Mme. Rozaine, white, and Raspail Improved, scarlet, not so much called for. The last-named is excellent for bedding, and is also a good winter bloomer. E. HOBDAV.

[With the above notes we received a very fine lot of flowers, consisting of most of the varieties mentioned above. The trusses were large, the individual tips also being excellent, and the colours rich and varied. We wonder the Zonal Pelargonium is not more grown for

winter decoration, as what could be brighter than a house filled with well-grown plants of the many fine varieties now in cultivation?]

NOTES AND REPLIES.

India-rubber plant.—(Can you kindly tell me what to do to an India-rubber plant which is growing up too near my drawing-room ceiling? It is within an inch or so of 8 feet high, and as it is well covered with leaves looks very handsome. A branch appeared this spring 1 foot 6 inches from the soil, and has now three leaves, and I have fancied indications of other such branches before, which have, however, not come to anything.—R. BAZA PLANT.)

[The only thing you can do is to cut back your India-rubber plant, and, unfortunately, that will disfigure it for some considerable time. We presume that it consists of but a single stem, with the exception of the shoot referred to as being 18 inches from the soil. We should advise in April next cutting it down to about 4 feet, which will doubtless cause the production of new shoots, and throw a good deal of vigour into the one that has already made its appearance. If, after cutting down,

Passifloras a free root-run, as they are great feeders, and, if planted in pots, soon exhaust the nutriment of the soil. Constance Elliot, I might add, is a capital sort for a glass porch, where it can be kept under control.—DEBRY.

Keeping Geraniums.—I have three dozen Geraniums which have been flowering, some in pots and the others in my garden. Will they be any good next year? I have no greenhouse or frame. What treatment do they require?—W. K. R.

[It is little use trying to keep your outdoor plants, we fear. You ought to have lifted them, and, after carefully trimming them up, potted them in September into as small pots as they would go, and stood them in a sunny window, potting them on in the spring and planting out in the usual way. It is now too late to do anything with them, as very likely frost will have touched them. Those in pots you can trim up and stand in the window, keeping them fairly dry through the winter, and when they break into growth next spring potting on as may be necessary.]

Aspidistras.—A friend of mine has sent me a few Aspidistras and India-rubber plants to look after for the

Zonal Pelargonium Duchess of Buckingham.

you can place it in a warm greenhouse for a time, the production of new shoots will be hastened thereby. We know a plant that was too tall for the room, and was then treated as above recommended, which is now (four years after) a fine specimen with half a dozen branches, all well clothed with handsome leaves. It stands in a large bay window, and, of course, occupies a considerable space.]

Passifloras.—Many houses contain Passifloras, like *cœrulea* and *Constance Elliot*, that would be much better if they were planted in some sheltered position out-of-doors—say, on a south wall. One sometimes finds them covering the whole of the greenhouse roof, thus admitting very little light to the place, and consequently other plants suffer. On the other hand, there are less rampant growers, such as *princeps*, *Imperatrice Eugénie* (with pink and white blossoms), *fulgens* (brilliant scarlet), and *kermesina* (deep crimson), that delight in the warmth a greenhouse affords, but do not fill the roof with abnormal growth, as do the first-named two. It is best to give

winter, as his house is closed. They are small plants and not in good condition, but have been reported by a jobbing gardener into 8-inch and 9-inch pots, which appear to me to be altogether too large. Would it be advisable to report them into smaller pots, say 6-inch, as such large pots are very clumsy for table use, or is it too late for this season? I keep them in the greenhouse from 45 degs. to 50 degs., although the *Chrysanthemums* taking up so much room just now they have to be crowded into a rather dark corner for the present.—SOUTH STAFFORD.

[You ought to put the plants into the smallest pots you can get the roots into. It was a mistake to put them into such large pots, more especially as the plants were in bad health. Give them the best position in the house you can, and be very careful with the watering-pot. Even then it is doubtful if you will be able to keep the India-rubber plant.]

Cypripedium insigne.—This, as all who grow it know, needs nothing beyond ordinary greenhouse treatment—i.e., where mixed collections of plants are kept, and houses are heated from October to April, there one may succeed with it. It flowers for months together, and individual blooms when cut will keep good for a month or more. Fibrous loam

and peat, in pots well crocked, are necessary, and one need not repot very often. When pot-bound give stimulants a little oftener. A little charcoal added to the compost is also desirable.—TOWNSMAN.

GARDEN WORK.

Conservatory.—*Primula obconica* makes a pretty group among Maidenhair Ferns now. It has received a bad name in some instances from those who have delicate skins, but I imagine very few people suffer in this way, and, of course, they need not grow them. Seeds sown early in spring in heat will make good flowering plants in 5-inch and 6-inch pots now, and in a light position they will bloom all the winter. There is a very pretty *Primula* of the Chinese section which has star-shaped flowers—*dellata*, I think it is called. It has a more graceful style of growth than the common form, and the flowers are more lasting, and therefore useful for filling small vases for the table. As a rule, the single Chinese *Primula* is not of much use for cutting, as the flowers soon fall. The star-shaped variety of the greenhouse *Ciacarria* is another useful break away from the old form, exceedingly valuable in the conservatory and for cutting. The plants are easily raised from seeds or offsets in spring, and if grown in freely, and shifted into 5-inch pots, plants a yard high and as much in diameter may be obtained. There is a considerable variety of colour, though I have not seen quite so much variety as in the old-fashioned class. I am afraid this type will not be of much use to the market grower. The plant is hardly sufficiently compact in habit, though of late years there has been a tendency to break away from the 5-inch pot, or, in other words, larger plants are wanted, and so the 6-inch and even larger pots come into use. Lilies of the longiflorum section recently imported should be potted and plunged for a time in ashes or Cocoa-nut-fibre in a cool-house or pit to make roots. These Lilies are cheaper than they were, and bulbs from Japan are in good condition—at least, so far as I have seen. This is a most useful Lily, and, by using retarded bulbs, it may be had in bloom all the year round. I was in a large establishment a short time ago, and saw a large number of bulbs coming on for flowering at Christmas. We still grow a few of *Harrisii*, but our principal stock is the giant variety of longiflorum—*lilium laucifolium* should be gradually ripened off.

Stove.—There is, or should be, plenty of colour in this house now. Besides *Begonias*, *Poinsettias*, and *Euphorbias*, there will be a few *Orchids* where *Orchids* are grown, and most people with a warm-house will grow a few *Dendrobies*, *Cypripediums*, *Calanthes*, etc., which flower more or less in winter in heat. *Manettia bicolor* is a pretty little twining plant; it is rather of a modest nature, and is pretty in a basket with the flowering sprays hanging down. It is easily propagated in sandy peat under a bell-glass. There will be plenty of *Eucharis Lilies* now. Weak liquid-manure will bring up the flower-spikes speedily. Where there is a number of plants it is quite possible to have a continuous supply of these flowers by introducing them in succession. I have seen them do well planted in beds of turfy soil in positions where there is a command of bottom-heat, but where it can be turned off whilst the plants are resting. *Gardenias* which have well ripened will soon flower in a warm, moist atmosphere, with weak liquid-manure twice a week or so. Of course, it is useless giving stimulants to plants which have not filled the pots with roots. The only time when the full benefit of liquid-manure can be seen is when the roots are abundant and are seeking for food. *Ipomoea Horsfallii* is a bright-flowered climbing plant; each flower, like most of the *Ipomoeas*, only lasts one day, but fresh blooms open every morning, so there is always a brightness present in the house. Night temperature now 65 degs., a little air to be given at 80 degs.

The unheated greenhouse will be very bright now with *Chrysanthemums*, and to keep the flowers as long as possible air must be left on night and day. We have had no frost to do any harm yet, but a damp, stagnant atmosphere

will soon spoil the blossoms, therefore constant ventilation is important. To follow the *Chrysanthemums*, there should be two or three good flowering bushes of *Laurustinus*, and for Christmas the *Christmas Roses* should be a special feature. I have seen in tubs grand clumps full of flower at Christmas. If a few well-grown roots were purchased now and potted in old rotten turf with some old cow-manure and enough broken charcoal and sand to keep it open and sweet, the plants will flower freely this season, and it will be money better spent than buying things which may give a little temporary colour and then die. *Coprosma Baueriana* is a pretty golden Japanese shrub that only requires protection in winter. The *Pernettyas* are very pretty berry-bearing plants, very suitable for the cold-house.

Violets in frames.—Stir the surface when necessary, and remove everything in the shape of dead or damaged leaves. Give air very freely when mild, both night and day, but keep out cold rains. If the soil is dry moisten it with liquid-manure which has been exposed to the atmosphere for some time, or add a little hot water from the boiler to raise its temperature. The hardiest kinds of Violets do not require anything in the nature of forcing, but the Neapolitan are more tender than the Russian family, and a little warmth will help them. If the plants have been well grown they will flower under any circumstances, but a little warm liquid is a help when the weather is cold. We always find Violets do well after Melons when a little of the summer warmth is left in the bed.

Winter Cucumbers.—Clear houses may be planted for succession at any time. I have tried several kinds for winter bearing, but I think a good form of *Telegraph* will be the most profitable. Cucumbers are a long time wearing out—but they do wear out. For many years we have been growing *Lockie's Perfection*, but it has not been quite so vigorous during the last year or two as formerly. *Emerald Beauty* is one of the *Telegraph* crosses, and is a very prolific kind. Winter Cucumbers require careful management, especially in the matter of top-dressings and watering. Do all the pruning required with the finger and thumb. Night temperature 65 degs. to 68 degs.

Window gardening.—Get the window-boxes filled outside. Bulbs, such as *Tulips*, *Hyacinths*, *Snowdrops*, *Squills*, and *Crocuses*, may either be used alone or in mixture with other things. A cheap early spring effect may be had with golden *Wallflowers* and *Forget-me-nots*. The berry-bearing *Pernettyas* and *Narcissi* are a break away from the common arrangements. *Pansies* will flower through the autumn and winter. I fancy there is not so much demand for small shrubs as there was in our district; they so soon turn brown when exposed to cold winds. Hardy overgreen Ferns are useful in shady positions.

Outdoor garden.—Gather up leaves and place in heap to make leaf-mould. We generally use them first to make hot-beds, as the heat can be utilised for forcing various things and the fermentation causes rapid decay. Leaf-mould may be used for many choice shrubs and flowers, and it forms a good mulch for *Lilies*, *Fuchsias*, or any other tender-rooted plant which is left in the ground through the winter. *Dry Brackea* is a very good protection for any plant which needs shelter from cold. When the roots are made comfortable the tops are not likely to suffer so much. Moss-litter-manure is a good mulch for bulb borders, and it may be left on the surface till the bulbs are starting into growth in spring and then be forked in. Borders containing many bulbs should not be disturbed now. This is one of the principal causes why bulbs disappear. When the border is disturbed now the loose soil holds the water and the temperature is lowered. Herbaceous borders are better mulched and left undisturbed till February. In replanting herbaceous borders, if the soil is of a clayey nature, lay the plants in and throw the soil up roughly for the atmosphere to work upon, and replant in February. Unless the replanting can be done in October, it is better to wait till spring, and all new plants bought in should be kept till spring.

Fruit garden.—This is the season for pruning fruit-trees and bushes, except *Nuts* and *Figs*, which should be left till after Christmas. *Gooseberries* and *Currants* are sometimes left, where birds are troublesome, till spring, but I have never adopted that plan, as the bushes are usually in a sorry plight when the birds have worked their will upon them. Better prune, and dress with lime and soot to keep off the birds. Besides keeping off the birds, the dressing has some value in cleansing the bark of the trees and bushes. Neglected wall-trees with long rough old spurs may have some of the old spurs removed. Work of this kind is best spread over several years. We generally begin with the *Pears*, and then follow on with *Plums*, *Cherries*, and the *Apricots* and *Peaches* last, except *Figs*, which in cold districts are generally covered till February or later. Some kinds of *Pears* bear fruit on the ends of rather long spurs. *Marie Louise* crops in this way. It is not difficult to tell the buds which are likely to produce blossoms by their shape. Blossom-buds are round and plump, wood-buds are more elongated, though occasionally one finds buds which appear to have been arrested in their growth before the work has been fully accomplished, and then the buds either fail to produce blossoms or the flowers are imperfect and fail to set. There is no difference of opinion amongst fruit growers about pruning wall-trees. It is in the free-growing bushes and pyramidal trees that mistakes are made.

Vegetable garden.—More Cabbages may be planted, and the earliest plants may have a little soil drawn up to them. Lettuces may be planted on warm borders to come in for spring. The Bath Cos is a favourite kind. There is a Cabbage-Lettuce grown in the neighbourhood of Norwich called *The Texter*, a good hardy Lettuce that turns in quickly. *Paris Market Cabbage* is a success under glass. Clear off all exhausted plants, including *Tomatoes*, *Peas*, *Cauliflowers*, etc., and turn up the land roughly to benefit from exposure to the atmosphere. If there comes very severe weather the green crops are likely to suffer, as they are soft and sappy. Those who have not beeded in their *Broccoli* may still do so if they wish to be safe under all conditions of weather. What a time the weeds have had lately! Woody land should be cleared either by digging the weeds in, or clearing them off and mixing lime in the heap to hasten decomposition. Dressings of lime are beneficial to old gardens that have been freely manured. It is easy to make mistakes in manuring, especially as regards the best time to apply it, and the right crops to plant on freshly-manured land. Potato land may be freely manured, and should also be deeply worked. Plants having long, tapering roots, such as *Beet* and *Carrots*, are better without manure. The usual course is to set apart for root crops land which has been liberally manured for the previous crop. Light, sandy land should not be manured in the autumn. E. HORDAY.

THE COMING WEEK'S WORK.

Extracts from a Garden Diary.

November 17th.—We are busy now pruning the fruit-trees and bushes, and this work will be in hand regularly for some time. Of course, special men who have been trained for the work will be employed on this job. A good pruner is the most useful man in the fruit garden, as it usually happens he is above the average in intelligence, and is also good at other work. It is difficult to keep the untrained man from doing too much. In pruning wall trees an old spur here and there is removed to encourage the production of young spurs near home.

November 15th.—All *Dahlia* roots have been dried and stored away; special care has been taken to secure the labels to the stems, as it is very annoying to lose the names. *Salvia patens*, of which we want a large stock, has been packed in sand safe from frost. *Gladioli* have been cleaned and placed in drawers in a frost-proof place. Double *Daffodils* starting in pots have been moved to a heated house; these want a good deal of water when starting.

November 14th.—The early *Chrysanthemums* are moved from the conservatory as the flowers

fads, and other later kinds take their place. Usually the house is rearranged every week and the necessary changes effected. We generally have Chrysanthemums up till the end of January. We find these late sorts very valuable, especially for cutting. There is a demand for long-stemmed flowers. Winter-flowering Begonias are lovely now. Some of the old sorts are still grown. *B. inchoisoides* planted in a light position continues to grow and flower all winter. *B. insignis* is also useful.

November 20th.—The bulk of the Potatoes and other root crops are covered with soil. Roots retain their flavour better covered with earth than when kept in sheds. Horseradish for winter use has been lifted and laid in on the north side of a wall, where it can easily be got at when the earth is icebound. Asparagus has been started in a hot-bed. Strong roots soon start in a genial temperature. The frames are matted up till the heads are coming through the soil, when light is necessary to give colour and flavour.

November 21st.—As fast as the trees and bushes are pruned a dressing of a suitable insecticide is applied; the borders or beds are then manured and forked over, but not deep enough to injure them. A spade is never used over the roots of fruit-trees, and no vegetable crops are planted near. We always put up a lot of Geraniums when the beds are cleared. Some of the large leaves are cut off, but the shoots are left on them, as we want them for cuttings later. The old plants are useful to fill vases next season.

November 22nd.—Pricked off a lot of seedling Ferns into shallow boxes in warm-house. We are always doing a little potting among young Ferns as they keep moving in heat, and there is a demand for fresh young plants in small pots for table decoration. Finished potting and boxing bulbs of all kinds. They are plunged in cold pits, from which they will be taken out as required for forcing. The demand for Narcissi for cutting is enormous. They take the place of the Chrysanthemums. Retarded crowns of Lily of the Valley are used for forcing, as the newly imported crowns do not start so quickly.

POULTRY.

Roupe.—A short time back I bought eight buff Orpington pullets, which I found out afterwards had roupe badly. They now appear to have recovered from it. Would these be quite healthy for stock, or would they breed a roupy lot of chickens? I want the eggs only for hatching, and intend to keep the stock pure.—LANEWOOD.

[This common and contagious complaint amongst poultry generally arises from overcrowding, bad ventilation in the hen-house, or dampness. It was unfortunate that your pullets had suffered from it before coming into your possession, but under careful and improved management it will not reappear in all probability. Their progeny will not inherit the complaint, and it will be some time before you use the eggs of your pullets for setting.—S. S. G.]

BIRDS.

Canary eating its feathers.—Can you suggest remedy for caged bird, Skinkin, suffering from some irritation of the skin, causing it to pick out its feathers as fast as they grow, also to peck at its feet constantly and appear restless and uncomfortable in cage? I have given Lettuce-seed, as you recommended a correspondent some time ago, also a fair amount of green food, but the trouble, whatever it is, appears chronic. The bird is not an old one, and has a bath most days.—C. F.

[This bad habit when once acquired is very difficult to cure. When a bird is kept in an overheated atmosphere or is allowed to partake too freely of sugar, sweet cake, and similar dainties, a gross condition of the system is often produced, with irritation of the skin, which will induce the sufferer to peck and scratch itself, and result in feather-eating. Canaries kept in a gas-lighted room will eat their feathers at other times than the proper moulting season, and consume the young quills as fast as they appear, and so remain bare to the end. Another cause of feather-eating is the presence of parasites in the cage, which prove very troublesome to the inmates. The presence of these pests may be known if white or greyish spots be observed about the woodwork of the inside of the cage, or, if a cloth or handkerchief be thrown over the cage at night, some of the

vermin will be found adhering to it in the morning. In this case the cage must be scalded in boiling water, and, when dry, painted over with Fir-tree-oil. Cuttle-fish-bone is a very excellent thing for keeping birds in health in purifying the blood, and you might find that providing a bit of this for your Canary to nibble at would help to cure it of the feather-eating habit.]

BEES.

Foreign Bees.—Would you kindly give me your opinion of five yellow-banded Italians or section honey? I am told the three-banded are bad comb builders and get Carniolans, as they have a bad name for swarming. I have heard that swarming bred therefrom are non-swarmers. What is your experience of them? Can this strain be had now, and where? I thought of trying a 2-inch ventilator in bottom of hive, and in April placing a crate under brood-nest with a few sections in it, and then as they worked these transferring them. I may say I have looked through back numbers of GARDENING, and see no reference to these points. I have taken it for ten years, and have read all your articles. In Vol. XVIII, p. 158, Mignonette is said to be the best annual for Bees, and no doubt it is very good. Of course, 1902 will long be remembered as a black year for honey. I have a large flower garden and Apple-trees. This, no doubt, with double-walled hives, which kept temperature more uniform, accounted for my having 40 lb. in sections from my two hives of blacks, although my neighbours have had practically nothing. I had a long border of Papaver nudicaule, which for four months was a delight to the Bees. I have never heard this mentioned before for Bees.—G. J. PADBURY.

[You are to be congratulated upon obtaining so good a honey harvest during the late disastrous season for Bees. No doubt your double-walled hives keeping the internal temperature uniform, together with your good yield of honey-flowers, had much to do with your success. Having good Bee pasturage close at home is a great acquisition in our changeable climate, as it enables the Bees to obtain supplies at times when long flights would end in disaster. Fruit trees when in flower should prove of great value in yielding early supplies, but how often are the Bees kept within the hive through stress of weather at the very time the fruit blossoms are at their best! Of course, there is much in autumn and winter management combined with spring feeding to encourage brood rearing. A large population ready to take full advantage of every possible opportunity of collecting honey is, no doubt, the secret of obtaining filled supers. Hives depopulated and low in the store department in the spring cannot yield surplus honey, the whole season being occupied in providing for the needs of the inmates. As to foreign races, I have long since come to the conclusion that they are unsuited to our climate, and should advise you to keep to your old friends "the blacks"—you have proved their value in your own case during the past season. Although Carniolans excel every other race in the beautiful appearance of their section honey, their disposition for excessive swarming is greatly against them. You would very possibly succeed in getting your Bees to work in sections under the floor-board, passing through a 2-inch ventilator, but you had better not try the experiment so early in the season as April; rather wait till the hive is full to overflowing with Bees before opening the passage-way. As a proof that honey will sometimes be stored below the hive, I once, on driving a stock of Bees for a cottager, found the cheese-box, which had been used as a stand for the straw skep, literally full of the most beautiful lot of white comb honey we ever had the pleasure of seeing. The Bees had passed down into the box through a crack under the skep.—S. S. G.]

LAW AND CUSTOM.

A gardener's notice.—I am engaged at a weekly wage of 18s. as gardener, but my master pays me monthly for his own convenience. What notice should I give to terminate service? I do not live in house or on grounds.—F. C.

[The question as to what notice is necessary to determine the service of a gardener engaged at a weekly wage is a moot one. But as the only factor in the case is that the hiring is at so much per week, I think your contract can be determined by a week's notice.—K. C. T.]

The Prize Winners this week are: 1, Miss J. Niblett, Uplam, Ledbury, for Californian Poppy; 2, Mrs. Cumberland, Codicote, Herts, for Lilies in old stone vases. Original

CORRESPONDENCE.

Questions.—Queries and answers are inserted in GARDENING free of charge if correspondents follow these rules: All communications should be clearly and concisely written on one side of the paper only, and addressed to the EDITOR OF GARDENING, 17, Pall-mall-street, Holborn, London, E.C. Letters on business should be sent to the PUBLISHER. The name and address of the sender are required in addition to any designation he may desire to be used in the paper. When more than one query is sent, each should be on a separate piece of paper, and not more than three queries should be sent at a time. Correspondents should bear in mind that, as GARDENING has to be sent to press some time in advance of date, queries cannot always be replied to in the issue immediately following the receipt of their communication. We do not reply to queries by post.

Naming fruit.—Readers who desire our help in naming fruit should bear in mind that several specimens in different stages of colour and size of the same kind are greatly assist in its determination. We have received from several correspondents single specimens of fruit for naming, these in many cases being unripe and otherwise poor. The difference between varieties of fruit are, in many cases, so trifling that it is necessary that two specimens of each kind should be sent. We can undertake to name only four varieties at a time, and these only in the above directions are observed.

PLANTS AND FLOWERS.

Lilium auratum (T. Drew).—This is quite hardy so far as the bulb and winter frosts are concerned. If planted 6 inches deep the bulbs will be quite safe.

Dahlia (H. R.).—There is, we believe, an "orange" glare of the garden, but no other shade so far as we know. Elfin, bright rose, is a decorative Pompon, while Chequfulness, Mercury, and The Duke are other Pompon Dahlias worthy a trial.

Some good Fesonies (W. H. L., Sherlock Smith).—The following are all good kinds: *Festiva maxima*, a grand massive white; *Eclatante*, deep rose; *Grandiflora*, light rose; *Purpurella*, saffron-rose and white; *Ima*, an *Houtte*, crimson; and *Lady Brooke*, white shaded flesh, a very lovely flower.

Carnations diseased (W. H. L.).—Your Carnations have evidently been attacked by the fungus known as *Helminthosporium echinulatum*. This fungus attacks between the two membranes of the leaf, and cannot be reached by any sulphuring process without injuring the leaves. The only thing you can do is to pick off all the infested leaves and burn them.

Sea sand (T. Drew).—This may be used with impunity in the garden for most things, but for tender subjects and for propagating it is safer that the soil be exposed for some time to the weather. It has been employed in a very large way. The danger is most likely to arise when without thought the fresh-arrived sand is employed indiscriminately. This should be done.

Feet-loving Lilies (T. Drew).—The really peat-loving Lilies are *L. auratum*, *elegans*, *Humboldtii*, and *pardallium*, etc. Quite a large number, however, may be grown in equal parts of peat, loam, and sand, while such as *Martagon*, *chalcidonicum*, *candidum*, *speciosum*, are best in sandy loam; indeed, the two first, with *L. giganteum*, do infinitely better in quite a strong loam, which, however, should always be of good depth and well drained.

Worms in lawn (R. L. Routh).—Lime-water is a good remedy as you say. Pour 2 gallons of water on 1 lb. of unslaked lime, or if more is wanted use the same proportions. Stir this well up and let the liquid stand for eight hours. Water the lawn with the clear liquid through a rose watering-pot during damp weather, giving a good soaking on the evening succeeding that on which the ground has been well moistened. This will bring the worms to the surface, when they may be swept up and cleared away.

Agapanthus and Crinum (New Subscriber).—The pots containing these may be placed anywhere free from frost, giving very little water to either during the winter months. The *Crinum* (*Amaryllis liotholida*) is quite hardy, and few plants repay better for a sheltered, warm position and deep, rich soil, with abundance of water in the summer. In very cold situations a little heap of leaves over the bulbs will keep them quite safe. In the case of your *Crinum*, very little water is necessary during the winter. You will find an article dealing with these in our issue of Aug. 9, p. 307.

The Martagon Lily (Thomas Drew).—This may be planted at once, and good bulbs will flower next year. The white *Martagon* does not recover so quickly when disturbed, and often takes two years before becoming established. The flowering of the *Helladonna* (*Amaryllis Helladonna*) depends upon the size of the bulbs. This also resents frequent removal. The bulbs should be planted in a warm border of deep sandy loam, peat, and old mortar, with plenty of sand or grit, even on clay soil. Cover the roots 6 inches deep just firmly. The soil should be quite 15 inches deep, and a south border is best. Dry bulbs may be planted now.

Lawn weed (E. T. R.).—The weed is not a species of *Polygonum* as we first suggested, but belongs to the Labiate order. To name it a flowering example is necessary. We should suppose its prevalence to be due to its rooting freely along the under surface of the stems, and also to free seedling. In these cases there is no remedy except weeding out, on the one hand, and sowing thickly the patches with Clover and Grass to outgrow the pest. Some weeds are difficult to eradicate, especially those that are self-increasing by seeds and by rooting along the under surface. Some of the weedy Veronicas do this, but continually working against them is the only possible way of overcoming them.

Lilies after flowering (Sonia).—Your Lilies should have been stood outdoors and watered till the leaves turn yellow, when the supply must be diminished, but at no time must they be parched up. Then when the flower-stems are quite dead repot them. If the bulbs are in good condition, pot 1 inch or even 2 inches wider than the present. They should be stood outdoors for a time in a

sheltered spot, under which treatment the roots will soon take possession of the new soil. Then when frost comes remove them to an ordinary frame or a greenhouse. As soon as they commence to grow see that the plants have as much air and light as possible. You will find as a rule that bulbs kept over from the preceding year flower somewhat earlier than freshly imported bulbs.

Daisies in lawn (Iris).—You may rid the lawn of lumpy roots by grubbing them out. This may be done at any convenient time now or during winter. Then in spring, about March, you may fork up the bare patches and work to some fresh soil. Any good garden soil free of weeds will do, and in April or May sow freely some good Grass seed. This you must protect from birds with low branches of trees or nets. If the lawn generally is low, get a load of very old manure and another of fine soil, and dress the lawn all over, sweeping it in well to the roots with a hard broom. A lawn requires attention in his way annually, particularly if it is much trodden on and worn in summer.

Amaryllis (E. S. B.).—If your bulbs are those of the greenhouse Amaryllis, or lippastrum, as they are now called, you will require to keep the soil rather dry from now to the end of January, when a rather more moist condition may be the rule. Firm potting with good soil, is not over rich, in what these things require. With a view to growth appearing, take care that the plant does not suffer from lack of moisture, and on the other hand avoid the commonest error of all—viz., that of giving too much water incessantly. These little drops more quickly reach the soil than any of the larger drops, and deposit a very much on the size of the bulb and the year in which it was grown last season. You cannot err, either, in following the above treatment with that given in a previous issue.

Pyrethrums, Phloxes, and Delphiniums (E.).—Of the first you do not say whether single or double-flowered kinds are required. We give some of the best. Single: Mrs. Bateman Brown, Hamlet, Sherlock, orion, Monarch, Snowdrift, Princess Marie, Pascal, and the double: Approdite, J. N. Twedy, No Plus Ultra, Mrs. Kelway, Wega, Pericles, Mont Blanc, Capt. Nares, Mrs. Voss, Melton, Duchess of Teck, and Lady Kildare. Double: Bayadere, Sphynx, Mrs. E. H. Jenkins, Mrs. Wines, Cornelia, Jocelyn, Countess of Aberdeen, Roi de Roses, Bacheaote, Etna, Edith, Wm. Robinson, and Mrs. Delphinium: Sir John Forrest, Imperial Jack, Rev. J. Stubbs, Sir George Newnes, Flying Fox, W. Scott, Perfection, Life Guardsman, Duke of Devonshire, Mrs. Blue, Percy Scott, British Empire, and many more novelties, and at present are directed to spreading lists of the best kinds in commerce, and you had at the usual rates.

Applying Liquid-manure (Thomas Dreer).—Liquid manure may be applied at any time while the plants are in a growing state with advantage. The majority of hardy plants are benefited by its use. Peonies, lilies, roses, pyrethrums, and all such in particular. Lilies need it, and unless they were old clumps growing on a rich soil where the soil is more or less exhausted, we did not use it. Even then the plants would be better lifted and replanted. Weak doses may be given once or twice in each week. A good liquid may be made by using a bushel of manure in a tub or tank, stirring it up for a short time. By also adding two pecks of soot, and in a coarse bag and only loosely tied, this may be used up and down to discharge its virtues. The liquid filtering from the above should be equal to 30 gallons, and to be employed at all strengths. By supplementing the soil with fresh from time to time, a good all-round effect may be kept up.

Yucca grandiflora (Australia).—This, known as the Yucca of Table Mountain, should be potted in a cask of light turfy loam and fibrous peat, mixed with one sharp sand and nodules of charcoal, the pots being drained. This should be done about Christmas or a week earlier, as the plants begin to root during the winter months. During this time they may be kept in a cold-house, the frost being carefully excluded, or at the cool end of an Odontoglossum-house. In the summer plunge the pots in moist material in the frame, when plenty of water may be admitted, and a thin shading from the sun can be given. A moderate supply of water should be given to the roots, and when the weather is bright in the early morning and the growth active, gentle syringing twice in the day will do good, as this prevents red-spider and black fly, both of which prey upon it and do much damage, killing the plants. Any plant nurseryman should be able to get you plants of this size.

TREES AND SHRUBS.
The Tamarisk, propagating (Seaside).—This easily increased by cuttings put under a handlight, even to the open air in spring or autumn. Any amount soil to which has been added plenty of sand will serve well.

Creeper for unsightly building (Iris).—There are many creepers for covering unsightly buildings. The most common is the large-leaved Virginia Creeper: *Ampelopsis hederacea*, *Clematis montana*, many beautiful species, the hardy Vines, *Vitis Coccinea* and others. All these handsome foliage and are quick in growth also.

Irish Yews too tall (K. O. H.).—The upright or tall Yews can, if too tall, be easily shortened without injuring them in the least. Their habit of growth is such, and the upright shoots are but sparingly produced, so if the tallest ones are cut back and a piece or two of wire passed around the upper part, it will serve to keep the minor shoots in their place and preserve the natural habit of the specimen. This may be done now, and carefully carried out it will be difficult to see that the plants have been shortened back at all. We cannot understand the necessity of training and cutting Irish Yews to a point, as they naturally assume that shape.

FRUIT.

Seedling Orange-tree (E. O. H.).—Your Orange-tree will doubtless flower in time, perhaps in eight or ten years from now. It will be necessary to exercise a considerable amount of patience. It will not bear any pruning, but early in the spring before growth commences, a better way will be to pick out the points of the three or four buds in order to induce a more bushy habit of growth. Our plant may be used as a stock on which to graft a better tree taken from a mature flowering plant, and this may

reasonably be expected to bloom in a couple of years or so.

Keeping Grapes (W. H. W.).—The very fact of your bottling your Grapes when mildew was on them accounts for the failure. Grapes to be kept must have special provision made for them. Dryness is the first consideration, and the Grape-room should also be heated, so that it may be possible to drive out damp if necessary. When once Grapes are placed in a room, the less frequently it is opened the better, as the admission of damp air must be carefully avoided.

VEGETABLES.

Celery decaying (C. H.).—From the appearance of the stick of Celery that you send, we should imagine that the seed has been sown too early, and that the seedlings had been allowed to remain too long in the seed-bed. The head showed that the plants had bolted, and that in earthing up some soil had been allowed to get into the heart, thus causing the centre to decay. When earthing up it is always advisable to tie a piece of matting round the plant to prevent the soil getting into the centre of the plant.

SHORT REPLIES.

J. C.—See reply to Augta, C. Coulbrook re "Perenniate and Bulbs," p. 488.—**Henry Stratley.** You can get plants of *Lychnis formosa* from any nurseryman who grows trees and shrubs.—**H. E. B.**—Move your Lilac to a sunny position, so that the wood can get well ripened, and do not cut in any way.—**T. Harris.**—You will find an article dealing with the Hollyhock in our issue of Sept. 6, p. 264, and also a note on the same in the issue of Sept. 27, p. 337.—**W. M. Cooper.**—No, mulch with Cocoanut-fibre or, if you can get it, Moss-litter-manure. The liveryman-manure is not necessary.—**E. Tisdall.**—You will not be able to keep your Pelargoniums as you suggest. Sawdust is one of the worst manures you could use for storing plants in. See reply to "W. K. R.," p. 490.

Scotus.—You ought to get one of the many weed-killers now advertised, and follow the directions sent therewith. They may be applied at any time.—**E. L. C.**

W.—We need to trouble about the loose bark on outdoor Vines, unless there are any insects present and you wish to dress with any insecticide, in which case pull it off, but do not scrape the rods in any way.—**Enquirer.**

The origin of the name is what you suggest.—Major Victor's Wife.—We know of no one who makes such burlesque as you refer to.—**G. Murray.**—Give the manure now, and apply the artificial manures to assist the crops that you put into the ground. If you manure well now, we see no reason for using artificial manure in the spring.

Blair.—The only thing you can do is, when mildew attacks the plants next season, to at once apply some insecticide to destroy it. See our article on "Growing Violets," in the issue of Nov. 1, p. 461.—**Constant.**

Forster.—See reply to "Cree," in our issue of Nov. 8, p. 478, re "Foreign Rhubarb."—**E. Gee.**—See reply to "Antique," re "Canary dying," in our issue of Oct. 25, p. 456, and to "Anon," re "Pears Cracking," in the issue of Oct. 11, p. 403.—**Forster.**—Hobday's "Villa Gardening," from this office, price 6s. 6d.

We do not quite understand your other query. If you want to buy the seeds, try M.M. Vilmorin at Cle, Paris, or Haage and Schmidt, Erfurt.—**E. C. A.**—Try *Passiflora coriacea* and its white form, *Clematis indivisa*, or *Lapageria rosea*, which last must have a peaty soil and plenty of drainage. We take it you can plant these out.—**Mrs. Delany.**—You cannot do better than fill the bed with some of the later-flowering Narcissus, such as *N. poeticus* or *N. p. orotus*. The spaces you have marked may also be filled with some of the many forms of Narcissus, or, if you prefer it, try Tulted Pausses; see reply to J. R. Phillips. In the rock garden, Narcissus springing from a bed of such as *Aubrieta*, *Arabis*, *Alyssum*, *Forget-me-not*, etc., would look well.

H. A. M.—Try Emerald Green Ivy, one of the best strong-growing kinds. We doubt, however, if it will succeed on a tarred wall.—**Aurora One.**—We should think one of the many contrivances you will find advertised in our column would answer.—**Coogee.**—We suppose you mean the Planet Jr. hoe, a very useful and labour-saving appliance.—**Iris.**—Unless you really want to get up a large stock, the best plan is to destroy the old rhizomes, only keeping those which have developed leaves.—**J. Wolfe.**—See reply to "Monmouthshire," re "Pergola for Roses," in our issue of Nov. 8, p. 472.—**Ignatius.**—You had better get "Hobday's Villa Gardening," from this office, price 6s. 6d.

NAMES OF PLANTS AND FRUITS.

Names of plants.—**Jas. McGeary (no box).**—20, Quite impossible to name from dried-up, withered leaves; 21, *Aster cordifolius* var.—**Major Victor's Wife.**—*Berberis Aquifolium*.—**Mrs. Ross.**—*Aster diffusus* horizontalis.—**Mrs. E. Saunders.**—*Salvia tarinacea*.—**T. P.**—*Monarda delicata*.—**J. Cocks.**—Evidently a washed-out bloom of *Georges Nabonnand*.—**Riduna.**—Specimen too dried up to be able to identify correctly.—**L. TARPAULIN.—I have a great quantity of large pieces of Tarpaulin, some new, but all of the best Navy canvas, purchased from Government, useful for covers for carts, waggon, and machinery, at 25s. per cwt. Lot suitable for covers for buildings, at 12s. per cwt. Cash returned if not approved of.—**H. J. GIBSON, Government Contractor, 22a**

C. R. SHILLING,

The Nurseries,

WINCHFIELD, HANTS.

ALL GOODS VERY CAREFULLY PACKED. PROMPT DESPATCH.

CRIMSON CLOVE CARNATION.—This is still the great favorite, and I offer good and well-rooted plants at 6 for 1s. 3d., or 2s. 3d. per doz., carriage free.

ASPARAGUS SPRENGERI.—The coming decorative Asparagus. A nobleman's gardener says he prefers it to Asparagus plumosus. Very easy to grow, and a really good thing. Fine young plants, just right for potting on, 2s. 3d. doz., or 15s. 10s. carriage paid.

CLEMATIS.—Plant now. A grand lot of plants, 4 to 5 ft. high, travel quite safely, in following varieties: *Durham* of Edinburgh, double white; *Jackman* superior, violet-purple; *Jackmanii* alba, single white; *Mme. Ed. Andre*, bright red; *Curry Queen*, pale flesh colour; *Earlham* rose, double white, flushed with rose. 3 for 4s. 6d., in 6 for 1s. 6d., carriage paid.

CARNATIONS, Marguerite varieties.—It is surprising how well these do in pots in a greenhouse for winter bloom. They are quite equal to the *True* varieties and potted up now will bloom all the winter. Five 8 in. transplanted plants, 1s. 6d. per doz., or 25 for 2s. 9d., carriage free.

BEGONIAS, fibrous rooted, of the Semper-virens type. For greenhouse decoration in the winter these are unequalled, as they continue to bloom all through the season. The plants I offer are strong and healthy, especially grown for winter bloom, and embrace all shades of colour; per doz., 2s. 6d., or 25 for 1s. 6d., carriage free. A remarkably cheap offer.

12 LARGE PLANTS, consisting of Aralias, Geranias, Palms, Cyperus, etc. selected for immediate decoration of halls, drawing-rooms, windows, etc., carriage free for 2s. 4d. This is a special offer, and cannot remain long open.

200 succession, strong plants, natural, carefully packed and carriage free, for 1s. 3d.

WALLEFLOWERS, fine strong plants, 100, in 5 best kinds grown, 2s. 9d., carriage free.

PANSIES, Finest large-flowering strain, strong plants, white, blue, pink, yellow, or red shades separate, 50, 1s. 9d.; per 100, 3s. 3d.; in all colours mixed, 3s. per 100, carriage paid.

CANTERBURY BELLS.—Very superior strain of this popular plant, strong plants, 1s. 6d. doz., carriage paid.

100 FINE STRAWBERRY PLANTS, in 4 best kinds, early, medium, and late season varieties, 3s. 6d., or 53 for 1s. 10d., carriage free.

HOLLYHOCKS.—Chater's finest double, very strong plants, 1s. 9d. doz., carriage free.

PERENNIAL SUNFLOWERS.—So much admired, and such a grand autumn flower. 12 fine plants, in variety, 1s. 9d., carriage free.

ST. JOHN'S WORT (Hypericum).—Very popular; produces quantities of large yellow flowers. For borders, bare places, growing under trees, on banks, etc., unequalled. Fine strong plants, 25 for 2s. 9d., carriage paid.

SILENE PENDULA COMPACTA, a lovely dwarf pink flower for spring blooming. Fine plants, 2s. 6d. doz., carriage paid.

ANTENNARIA TOMENTOSA.—One of the finest silver foliage edging plants grown. Flowers only 2 in. high. 1s. 6d. doz., carriage free.

THREE BEST HARDY PERENNIALS for cutting and for garden. *Gallicarda*, *Coropsis*, and *French Pyrethrum*. They are perfectly hardy, will grow anywhere, and produce quantities of brilliant blooms, which last a long time when gathered. Fine plants of either, 1s. 9d. doz., or 6 of each for 2s. 6d., carriage free.

30 SHRUBS and TREES, Evergreen and Deciduous, 2 ft. to 6 ft. high, in great variety (about 12 kinds), 6s. 9d. per rail, carriage paid.

12 CLIMBING PLANTS of sorts, Honey-suckles, Jasmines, Virginian Creepers, etc. (6 kinds altogether), 2s. 6d., carriage free.

12 HANDBOOK HARDY EVERGREEN SHRUBS, assorted for pots and boxes, 2s. 6d., carriage free. These are also suitable for porches and cold greenhouses during the winter if put in pots.

250 BULBS, including 12 choice Hyacinths and a good assortment of Tulips, Crocuses, Narcissus, Anemones, etc. 5s. 6d.; half quantity, 3s. carriage free. This Collection is suitable for growing in glasses, pots, or window-boxes, and is a very cheap and useful selection of bulbs.

3 RED, 3 White, and 3 Black Currants, 3 Gooseberries, 12 Raspberry-canes, and 24 Strawberry-plants for 4s. 6d., strong and healthy, carriage free. Very best kinds only.

GOLDEN FOLIAGE SHRUBS, hardy, for window-boxes, etc. 12, in variety, nice bushy plants, for 3s. 9d., carriage paid. Silver foliage same price.

ARISTO CLIMBERS.—Golden and Silver Variegated *Arales*, 10d. each; *Bignonia radicans*, 6d. each; *Aristolochia Siphon*, 1s. each; *Amelopsis Vesicifera*, 6d. each; *Amelopsis verticillata*, 6d. each; *Hops*, 3d. each, 2s. 6d. doz.; *Jasmin*, white or yellow, 6d. each; *Honeysuckle*, 4d. each; *Vincas*, 6d. per doz.; *Wistaria*, 1s. each; *Pyrola japonica*, 6d. each; *Veronica*, 3d. each, 2s. 6d. per doz.; *Periploca graeca*, 6d. each, 5s. doz. All strong plants, carriage paid.

ROSES (TEA-SCENTED VARIETIES).—1 doz. strong plants, in 12 of the best and latest kinds grown, and which will give the greatest satisfaction, 1s. 6d., or 6 for 4s.

ROSES (HYBRID PERPETUALS).—Very fine bush plants, our selection of kinds, but only the very best and latest kinds. Carefully packed, correctly labeled, and sent carriage paid, at the following prices: 25 for 10s. 6d.; 12 for 5s. 6d.; 6, 3s.; or sample 3 plants for 1s. 6d.

ROSES (STANDARD).—Good heads and stems, best varieties, only 15s. doz.; half-standards, 12s. doz.; or dwarf standards, with stems 1 1/2 to 2 ft., 9s. doz. Carefully packed and carriage paid. Half or quarter doz. supplied.

ROSES.—Very large plants of *Maréchal Niel*, *Libaire de Dijon*, *Nipheto*, *W. A. Richardson*, 1s. 9d. each, carriage paid.

JAPANESE WINEBERRIES, 6l. each, 5s. doz.; Logan Berries, 1s. 9d. each; the White Black Currant, 2 for 1s.; 100 *Alaragus* Strawberry-plants, 2s. 3d.; the Strawberry Raspberry, 2 for 1s. 3d.; the Blue Spruce, 2 for 1s. 6d.; the Marbled Tree, 2 for 1s. 6d.; the Date Plum, quite hardy, 1s. 3d. each; the Double-flowering Ribes, scarlet flowers, 2 for 1s. 6d.; the curious Green-flowering Rose, blooms a green colour, 1s. 3d. each; the Scarlet Lady of the Valley (*Daphneria*), 6 for 1s. 6d. All the above are quite hardy. Carefully packed and carriage free.

SWEET BRIERS. The real old-fashioned kind, which is so highly valued. Should be in every garden. Very strong plants, 2s. 9d. doz.; 50 for 9s., carriage paid.

DELPHINIUMS, very fine plants, the best strain, 2s. 9d. doz., carriage free.

CARNATIONS AND PICOTEES.—Finest named varieties; cannot be surpassed; strong, well-rooted layers. A dozen, in 12 best kinds, 5s. 6d., or 6 for 3s., carriage paid.

CARNATIONS. Large plants raised from the finest seed ever sown, 1s. 6d. doz., or 25 for 2s. 9d., carriage paid.

PHLOX, PERENNIAL.—Very choice varieties; strong plants, 2s. 9d. doz., carriage paid.

VIOLETS.—Splendid clumpers, specially grown for winter forcing. Put or put in frames now. Thousands sold last season. Best kinds are: *Antonia*, *Arctian*, 2s. 6d. doz.; *Comte de Hericourt*, double white, 3s. 6d. doz.; *Czar*, 2s. 9d. doz.; *California*, 2s. 6d. doz.; *Marie Louise*, 2s. 6d. doz.; *Mrs. J. J. Astor*, 3s. 6d. doz.; *Princess of Wales*, 2s. 6d. doz., carriage paid.

CINERARIAS.—Finest large-flowering and most brilliant colours; 1s. 6d. doz., or 2s. 2s. 9d., carriage paid.

PRIMULA SINENSIS, best strain, grand fringed flowers, fine plants, 1s. 6d. doz.; 25 for 2s. 9d. doz., carriage paid.

PRIMULA HONICICA, same price.

BEGONIAS, perpetual-blooming, of Gloire de Lorraine type, grand in winter, fine plants, assorted colours, 2s. 6d. doz., carriage paid.

BROMPTON STOCKS, very best strain, 1s. 9d. doz., carriage paid.

HOLLYHOCKS, Chater's fine double, 2s. 3d. doz., carriage paid.

PANSIES, Trimardeau Giant, very fine, 50, 7s.; 100, 3s. 6d., carriage paid.

SWEET WILLIAMS, best large-flowering, 50 for 2s. 3d.

PALMS, Kentias and Latantias, grand plants, 12 to 18 in. high, 6 for 2s. 9d., carriage paid.

CYCLAMEN PERVICUM, very best large-flowering strain, 1s. 9d. doz., carriage paid.

CYPERUS ALTERNIFOLIUS, a grand room plant, 6 for 1s. 3d., carriage paid.

6 ASSORTED PLANTS for table or room decoration, including Palms, Aralias, etc., for 1s. 9d., carriage paid.

LIBONIA FLORIBUNDA, fine for winter, 6 for 1s. 9d.

GERANIUMS, specially prepared for winter bloom, 12 for 2s. 6d., carriage paid.

ALPINE STRAWBERRY.—The flavour of a these is delicious, and fruit is found on them all the summer. Fine plants, 50 for 1s. 3d., carriage paid.

IVY, Gold or Silver Variegated, fine plants, 3 for 2s. 6d., carriage paid.

FERNs, assorted kinds, very fine, 2s. 6d. doz., carriage paid.

STREPTOCARPUS, best new hybrid, fine plants, 1s. 9d. doz., carriage paid.

CYCLAMEN PAVLO, the new Butterfly Cyclamen, 6 for 1s. 9d., carriage paid.

NICOTIANA SYLVESTRIS, the new large-flowering sweet-scented Tobacco; fine white flowers; strong plants, 1s. 6d. doz., carriage paid.

IPOMEEA LEARI, a beautiful greenhouse climber with large Convolvulus like flowers, 6 for 1s. 9d., carriage paid.

TECOMA SMITHI, the beautiful new greenhouse plant, 4 for 1s. 3d., carriage paid.

6 RIVINA HUMILIS, 1s. 3d. FICUS ELASTICA, large plants, 2 for 2s. 9d., carriage paid.

HOYA CARNOSA, beautiful wax flowers, 3 for 1s. 6d.

6 PASSION-FLOWERS, 1s. 9d. 12 ISOLEPIS GRACILIS, 1s. 9d.

VINCA ROSEA, a beautiful greenhouse plant, 6 for 1s. 9d.

ARUM, the large-flowering kind, very fine, 6 for 1s. 9d.

ARUM LITTLE GEM, a lovely plant, 4 for 1s. 3d.

PEONIES, finest double, in beautiful colours of this fashionable flower; large plants, 6 for 4s., carriage paid.

FRUIT TREES.—I have many thousands of bush and pyramid Apples on the Paradise stock; grafted on this stock the trees fruit when quite young, and are most suitable for garden planting. All the best sorts, 12s. doz. Also all other kinds of fruit-trees. Catalogue gratis and post free.

VEGETABLES.

RAISING TOMATOES.

Always tell me the best time for sowing Tomato seeds to have the plants on as early as possible in greenhouse, minimum temperature 45 degs. in winter, also what kinds you recommend.—HOPKIN.

[Where convenience exists for the steady progress of seedling Tomatoes there is a gain in autumn over that of early spring sowing. The object of the grower is that of securing ripe fruit at the earliest possible date. Plants raised in autumn are hardier, can be given cold treatment, and they respond well to warmer treatment and repotting as spring comes round. By many it might be supposed that the present is an unusually early period to sow Tomatoes for obtaining ripe fruit next summer, and so it undoubtedly is. That, however, is not the point. The aim of every grower is to obtain a maximum crop with a minimum of uncertainty and labour. Some may say, why sow seed in autumn when it can be just as well left until January or February? An answer may be found in many a market nursery where Tomatoes are grown by the ton. Market growers are not likely to err in sowing in the autumn if this could be deferred with the certainty of the same and being gained by sowing in the spring. At the same time, it must not be thought that the amateur's solitary greenhouse, heated only in the worst weather, is likely to furnish the conditions to make autumn sowing a success. Tomatoes must have a little more warmth than obtains in any such structures, and yet there are many places that the right conditions are available. One important point to observe is to keep the plants near the glass and elevated on a shelf. Unless this is done they soon become drawn and in a measure spilt. A shallow box, say, 1½ inches deep, would be even better than pots for sowing in, and if the seeds are so placed that every plant stands quite clear of a neighbour, early repotting is unnecessary. Leaf-mould or Cocoa-nut-fibre mixed liberally with the soil will ensure a better ball of roots when transplanted, and when this is done in winter place the stems against the sides of the pots and bury up to the seed-leaf in the soil. In the spring everyone knows how quickly Tomatoes suitably accommodated grow; but in the autumn the case is different, as progress is slower. In this way a sturdy growth is built up, so that when the time for real work commences the plant is well developed and an earlier set is secured. To obtain this, restricted root-space, plenty of light, careful watering and ventilation must be attended to. Tomatoes are now such an every-day necessity that efforts are made to acquire a supply over as long a period as is possible, and though at the time of the earliest ripened fruit there is abundance of imported Tomatoes, the home-grown fruit is much preferred. The month of October is probably the best time for seed sowing, there being then sufficient sun-heat to help on the plants in their early stages of growth, which, of necessity, is slower than in March. In point of early ripening there is, perhaps, none better than Earliest of All, and Early

Ruby is earlier than some. Variety, however, is not so much a matter of concern, because any sort adapts itself to autumn sowing, and even if they are slightly slower in ripening, Becker's XL All, Lister's Prolific, and Holmes' Supreme are varieties I should choose, because of their freedom and smoothness of outline. These are all of medium size, the first-named being the largest fruited of the three, and, though scarcely large enough to satisfy some exhibitors, it is nevertheless good for every other purpose.—W. S.]

NOTES AND REPLIES.

Forcing Rhubarb.—I have been forcing Rhubarb for the last two years, taking the roots up from garden about this time and putting them in my greenhouse, which I keep at about 60 degs. I have been successful in forcing the Rhubarb, but when I planted the roots back in the garden about April they all died. I have always thought they should live and produce some sticks the following year.—S. J.

[Each year you must plant some seedlings or divisions, and so keep up a constant supply. Your latest forced roots could be divided for planting, taking care that they are well hardened off before planting out. To continue forcing you must have at least a quarter of an acre of ground at disposal, and so be able to make a plantation every year. The crowns will be of no use for forcing until the third year. The first year you must not pull any stalks, and even during the second year only a few stalks are used, while in the third year a fair crop may be obtained.]

Tomato-houses.—I am about to take the roofs off some cow-sheds, lower the walls, and convert them into Tomato and Cucumber-houses, about 200 feet. I propose lowering the walls to 3 feet 6 inches, the ridge 9 feet from ground level, the borders about 8 feet wide, with paths 2 feet 6 inches, and two rows of 4-inch pipes down each side. Total width of ground covered, 40 feet. Would it be advisable to have glass partitions down the centre to form separate houses? Would you also kindly tell me what depth of soil should be placed in the borders? I can obtain any amount of turf from the road-sides, also heaps of road scrapings and sweepings. Would they, singly or mixed, make a suitable soil for growing the above crops? Any suggestions you may make will be highly appreciated.—FRANCOIS.

[So far as we gather from your description, the method of reconstruction is quite correct. It is quite unnecessary to have a partition in the house, but in lieu thereof, and for greater convenience generally, we should prefer houses of 100 feet long to others of double that length. In these crops there is of necessity a change of soil required now and then, and wheeling every barrowful, say, 100 feet from the centre to the door where houses are 200 feet long, makes a long, laborious task of the work. These long houses, too, are not so convenient in many ways. In heating, for instance, where a 200 feet range exists, a small rise all the way throws the flow pipe very high up, but with houses 100 feet long the range may be right and left of boiler, and worked conveniently as well as heated with greater uniformity. Many people have put up long houses in the past at great cost, and they would not do so again, because the error is clear and the cost of working obviously greater than in smaller places. If the borders for soil are to be 8 feet wide, 12 inches or 18 inches of soil will be ample for the borders, placing

good layer of cow-manure at 12 inches deep. The turf you speak of would do quite well, but we should prefer it for use after it had been some months stacked, and as you appear to have a good supply at command, we suggest you stack it, mixing with it a fourth part of manure, together with bone-meal, soot, and lime in separate layers. In this way, and by turning the heap once at least in six months, you will have at command a mass of invaluable material, which on your own showing can be added to at leisure. Thus prepared the soil is much more nutritious for the crops.]

Growing Mushrooms (Anxious).—Mushrooms are not difficult to cultivate by those who have had experience and have a good supply of suitable manure and good spawn. You should begin on a small scale till you have mastered some of the difficulties of the subject. To ensure regular success there must be a good supply of manure from stables where the horses have hard, dry food only, care being taken that no manure from sick horses is used. After the longest litter has been shaken out the short manure must be turned every three days for a fortnight to drive off some of the surplus moisture. When in a hurry the experienced grower will mix one in four or five of dryish loam with the manure to absorb the moisture, and in this way the beds may be made up in three or four days after the manure comes to hand. The beds in a cellar should be of a manageable size. If round the wall sides 3 feet wide and from 12 inches to 15 inches deep will be necessary. Build the beds up firmly, and when the temperature is fairly steady at something like 85 degs. (we need not be particular as to a degree or two) the bricks of new spawn should be broken up into pieces 2 inches in diameter and inserted 2 inches to 3 inches deep and 9 inches apart all over the surface of the bed, and when the bed has been formed again and no appearance of the heat rising above 90 degs., place on the bed 1½ inches of leamy soil and beat down firmly. In a cellar it may not be necessary to cover the beds, though generally a covering of coarse hay is beneficial in keeping the bed in an equable condition of heat and moisture.

Protecting vegetables from frost.—Care will now have to be taken that Lettuce and Endive which are being preserved in frames are not injured by frost, as where these are of fairly large size decay sets in very rapidly if frost is allowed to reach them. In the case of severe weather the lights should have a thick covering of litter or Bracken placed upon them, and if the frost continues, allow it to remain on until it has passed away. The sides of the frames will also require some litter placed around. On the other hand, ventilation will have to be attended to on all fine days. Cauliflowers will also need protecting, but these must not be unduly coddled. Parsley will also require attention. Once let Parsley become injured by a severe frost or beaten down by snow, decay will rapidly set in. Parsley must not upon any account be coddled, a free circulation of air being essential during damp or mild weather. Protection from frost and snow and a free circulation of air are other ones are not needed.

TREES AND SHRUBS.

A SEASIDE SHRUB (DESFONTAINEA SPINOSA).

In many districts of England, especially near the sea, this Chilean shrub will both grow and flower in a satisfactory manner, but where such

Desfontainea spinosa.

is not the case it is well worth the protection of a greenhouse, as its blossoms are very striking and distinct in character. The plant is of a sturdy, freely-branched habit of growth, with foliage very much like that of a Holly, while the drooping, tubular-shaped blossoms are scarlet tipped with yellow. In Devon, Cornwall, and many parts of Ireland it is at home, and so is the Fire Bush (*Embothrium coccineum*) from the same region, which, when laden with its clusters of brilliant Honeysuckle-like blossoms, is such a gorgeous sight as to recall some native of the Tropics. The *Desfontainea* may be propagated by means of cuttings taken when the young growth is about half-ripened, inserted into well-drained pots of sandy soil, and kept close in a temperature slightly higher than that in which they are grown. T.

CLIPPING TREES AND SHRUBS.

At this time of the year, when gardens are being cleared of summer bedding plants and tidied up ready for the winter season, it is very distressing to see the many beautiful hardy Evergreens that make gardens bright and cheerful having nearly all the growth they have made during the past summer so reduced. It is all very well to clear off decaying plants, or the luxuriant shoots of climbers or trailers, but why Evergreens, that are planted for their warm, cheerful effect in winter, should be so barbarously treated just as the winter is coming on passes my comprehension. In this locality the many varieties of *Euonymus*, both green and variegated, are very much in evidence, and very beautiful they look clothed with glossy, shining foliage; but they seem a mark for the shears, for in nearly all the public parks or promenades one finds men busy at work clipping them into forms that are really eyesores to anyone who delights in naturally grown trees or shrubs. If it is necessary to restrict them to any specified height or size it could just as well be done by thinning out the shoots with a knife, and leaving the younger shoots with the foliage intact. This clipping mania is copied by nearly all the owners of small gardens, who seem to consider it the correct thing to do. In this way no trace is left of the naturally beautiful form that the shrubs would assume if left to develop their growth in a natural manner.

JAMES GROOM, *Gosport.*

Moving a Guelder Rose.—I wish to transplant a large standard Guelder Rose. Can you advise me the best means to adopt and the best time of year to do so?

Digitized by Google

It has made a good deal of new wood this year. Would it be necessary to cut this back before transplanting?—MARY M. ANDREWS.

[No need to cut the plant back in any way. You ought to move it at once, taking care that the hole into which you put it is sufficiently large to allow of the roots being spread well out. Cut off any damaged pieces of root and water well in, putting a mulching of rotten

manure over the roots so as to retain the moisture. Dig out a trench about 2 feet from the trunk, and then work underneath the ball of soil, taking care to get as much soil with the roots as you can. It is a good plan to put a mat round the ball of soil to keep it firm while being moved.]

PLANTS AND FLOWERS.

ORCHIDS.

CATTLEYS MAKING SECOND GROWTH.

I HAVE noticed several of my Cattleyas this season have made, and are now making, a second growth, the first not having produced sheaths as usual or flowered, probably owing to the cold nights during the summer and want of the average sun heat.—F. W.

[It is not at all unusual for Cattleyas to produce secondary growth—in fact, there are many species and hybrids that need to be specially treated to prevent this. I will take three of the kinds which commence making their growth during the summer—*Cattleya Warscewiczii* (*gigas*), *C. Dowiana aurea*, and *C. labiata*. The first-named species frequently commences to grow in May and through the months of June and July, when the outside conditions are such as to afford encouragement to the development of growth—in fact, it often occurs that the growth ripens and flowers are expanded by the middle or end of July and early in August. This being the case, the conditions then prevailing generally tend to cause the flowers to fade quickly, consequently there is little strain on the plants, and the liberal treatment afforded in the matter of root-moisture in the endeavour to finish the yet undeveloped growth often causes the secondary growth to appear before the previous pseudo-bulb has reached maturity. Plants of this species that have failed to flower are still more

likely to develop secondary growth. Such growth, if started before the end of August, with due encouragement will generally ripen in a satisfactory manner. Growths appearing after that period are generally difficult to manage and need a great deal of encouragement and careful treatment to induce them to produce pseudo-bulbs of normal size and to get them thoroughly ripened. One of the principal items in the treatment of plants developing winter growth is to see that they are placed in the warmest house available, and in such a position that they may obtain the maximum amount of light. Careful watering also is necessary, or the moisture accumulates inside the bracts which surround the pseudo-bulb, and quickly turns the outer covering black at the base, this frequently leading to the ultimate decay of the pseudo-bulb. This latter difficulty generally occurs when plants are grown under such conditions that they cannot obtain sufficient light to properly ripen the base of the pseudo-bulb. It is a good plan to suspend plants with secondary growth close to the roof-glass.

My remarks on *C. Warscewiczii* will apply also to the other species mentioned, and to the hybrids which usually flower in autumn or early winter. I would advise you to place plants of these kinds under cooler and drier conditions immediately after the growth reaches maturity, or after flowering. It is a better plan still to mark the particular kinds which are producing secondary growth, and place them under cooler conditions so as to keep the plants dormant and retard growth for two or three weeks. This generally produces more satisfactory results. It has, no doubt, been a trying season for all kinds of plants, and things generally are unusually late. I am inclined to think too liberal treatment must have been the cause from which you complain. I live not much further north, but have been afraid of the results that would be obtained from the unusual late starting owing to the cold spring and summer with very little sunshine. The last few weeks, however, and the continuation of milder weather have brought more favourable results than could reasonably have been expected. It will be desirable, perhaps, to keep the plants cooler to prevent the difficulty of which you complain occurring another season. *Cattleya Trianae*, *C. Mossii*, *C. Mendeli*, and others, often flower without producing flower-sheaths, so that if you can ripen the pseudo-bulbs properly, you may get the benefit of both growths flowering in proper season.—H. J. C.]

Snowflakes.—The Spring Snowflake (*Leucojum vernum*) should be found in every

The Lily of the Field (*Stembergia lutea*). (See page 47.)

garden where early spring flowers are grown, and bulb buyers have now an opportunity of getting it in this autumn. Snowflakes like a light and fairly rich soil, and when once

established never fail to bloom, their green-tipped white bells, produced on somewhat stiff stalks, having a very pretty effect in the borders. *L. carpaticum*, blooming a little later, has larger blooms. The Summer Snowflake (*L. aestivum*), also white, may be planted in the autumn.—LEAHURST.

OUTDOOR PLANTS.

STERNBERGIA (LILY OF THE FIELD).
PRETTY and very interesting hardy bulbs, which deserve to be better known. The autumn Crocuses help to carry us through the dull months, but the flowers of the Sternbergias, being of much firmer texture, are able to withstand a far greater amount of bad weather than those of the Crocuses, and are thus better adapted for our climate. One source of failure with Sternbergias and other bulbs is moving them at the wrong time, or before growth has fully developed. What they want is thorough ripening in summer and slight protection, such

S. LUTEA.—This is the winter Daffodil of Parkinson and a pretty hardy plant, best on some gravelly soils. The absence of seed on this bulb in a cultivated state is remarkable, seeing how plentiful it is and how freely it flowers in many parts of the country. The bulbe must be large before they will bloom freely. There is a narrow-leaved form of this named *angustifolia*, which flowers very freely and is of rather more vigorous growth than *S. lutea*.

S. GRECA, from the mountains of Greece, has very narrow leaves and broad perianth segments.

S. SICULA is a form with narrower leaves and segments than the type, while the Cretan variety has considerably larger flowers.

S. MACRANTHA, introduced by Mr. Whittall from the mountains of Smyrna, is, as will be seen by our illustration, a very handsome form. The leaves are each about an inch broad when fully developed, flowers bright yellow, appearing in the autumn.

The rarer kinds should have a place in our

ness of ice prevailed. Walking some distance from the pond you are sensible of a pleasing Almond perfume being wafted to you. The oblong leaves spread out on the surface and the buds rise a few inches higher, covered by a green conical cap, which the expanding flower pushes off. These very pretty and peculiar white fragrant blooms are produced for many months. I enclose a few, which I trust will reach you in such a condition that when placed in water they will diffuse a pleasant perfume in your office. Every flower throws off about fifty seeds; these are contained in filmy envelopes and for a short time float about on the surface, then burst their cases and sink to the bottom, and when doing so a small shoot about one-third of an inch long is already visible.

My mode of growing the Aponogeton may possibly interest your readers. I procure an empty paraffin-oil cask, saw it in half to make two tubs, then drop a piece of lighted paper in to burn out the remains of the oil. When the flame gets low sprinkle water from a can to prevent the tub itself being burnt. I

The large-flowered Lily of the Field (*Sternbergia macrantha*).

as dry litter, during the winter. In sandy loams, and fully exposed to the sun, the bulbs will get the necessary ripening without being lifted, and the best plan will be to leave them undisturbed until they attain flowering size. We have even known the plants thrive on stiff soils without being moved.

S. COLCHICIFLORA.—This is one of the old garden plants, having been cultivated by Clusius and Parkinson. It is described as fragrant, and perfuming, with its Jessamine-scented flowers, the fields of the Crimea about the Bosphorus. The leaves are narrow, and come with the fruit in spring; and the sulphur-yellow flowers appear in autumn at about the same time as those of *S. lutea*. It is found on dry, exposed positions in the Caucasus and Crimea, and is hardy in this country. *S. dalmatica* and *S. pulchella* are varieties.

S. FISCHERIANA is nearly allied, and has the habit of *S. lutea*, from which it differs chiefly in flowering in spring instead of in the autumn.

bulb borders, or on rocky borders in gritty or open soil, associated with the rarer Narcissus and the choicer hardy bulbs. The effect produced by *S. lutea* when grouped near the shelter of walls is very fine when the plants are in bloom.

THE CAPE POND WEED (APONOGETON DISTACHYON).

THIS beautiful, interesting, and sweetly-fragrant aquatic is not so extensively known and so generally cultivated as it deserves. It is suitable for the smallest garden, hardy, and requires only a minimum of attention. When first introduced into this country from the Cape of Good Hope, many years ago, it was deemed scarcely suitable for our climate, and in the Edinburgh Botanic Garden was grown under glass, but by some accident, or perhaps designedly, a few seeds found their way into the open pond, where the plants soon spread over a considerable space, and proved that they required no protection, even when some thick

then sink the tub in the ground till the edge is about 3 inches above the soil, put about 9 inches of ordinary garden soil in, insert the plant in the centre, and fill up the tub with water. No further attention is required beyond filling up the tub occasionally to compensate for evaporation. I have seen the Aponogeton flowering in a large inverted bell-glass placed on an office table. It grows at Kew in the outdoor tank contiguous to that containing the beautiful Nymphaeas.

A. B. HERRERT.

Morden, Surrey, Nov. 8th, 1902.

THE TREE-PEONIES.

THE Moutan Peony of northern China and Japan is one of the handsomest of all our shrubby garden flowers. It was introduced as long ago as 1789, and very noble specimens exist here and there in old English and Irish gardens. It has long been cultivated in the gardens of China, and of late years many very fine seedling varieties of the most varied colours

have been imported from Japanese nurseries. Some of these have white, flesh-pink, rosy-salmon, lilac-purple, or crimson flowers, with or without darker markings at the base of their satin-like petals. There are single, semi-double, and full double forms. The fine old specimens of *P. Mouton*, to be found in gardens wherein they were planted, in some cases a century or more ago, are often 5 feet to 8 feet in height and 10 feet to 15 feet in diameter, producing in good years from 50 to 200 or more flowers.

It must be clearly recognised, however, that these old examples were not grafted, but have always existed on their own roots, propagation being effected either by layering the lower branches or by the careful division of old clumps. It is important to remember this, because the plants as now imported by the hundred or thousand from the nurseries of Japan are all grafted on a long-rooted and coarse-growing stock, and even in pots many minor troubles and losses innumerable have been experienced in their cultivation. The plants flower well the first season, carrying from one to three or more flowers, and then every succeeding year is marked more or less by failures in growth and in flowering. All this is very disappointing. Some cultivators have in part succeeded in remedying the evils of grafting Tree-Pæonies by planting them so deeply in tubs or pots, or in mounding up their stems so high, that roots have been induced to appear above the union between the wild stock and the young scion. The demand in Japan is now so great that one can scarcely expect the gardeners there to abandon the system of grafting now in vogue in favour of sending us own-rooted divisions or layers on their own roots. As it is, the grafting suits growers and dealers in Japan, who make these plants to sell, rather than to grow on permanently and form large and healthy bushes in the open air, as their older prototypes have done in many places. It is a great pity that grafting as a means of increase has been resorted to in the case of the Tree-Pæony, seeing that it may be layered so easily, and that the plants growing on their own roots live so much longer. Layered Pæonies, like layered Rhododendrons, are free from suckers, which are often, even if not always, a nuisance with grafted plants.

Our advice to all who have failed to grow the newer-imported varieties in the open air is to so treat them that they are sure that the scions are rooted above the graft line before they think of planting them outside, and, moreover, to harden off the plants carefully before the experiment is made. Tree-Pæoniae are quite hardy in deep, rich, warm soils near the sea almost everywhere, but especially so in the south and western parts of the British Islands. The real danger comes with the late spring frosts of March and April, hence it is advisable to select a sheltered position for them where they are shaded from the sunshine of the early morning, which otherwise is very likely to blacken their early appearing flower-buds and foliage. A south-western exposure suits them best, and we have noted splendid specimens in such aspects.—*Fidd.*

PENTSTEMONS FROM SEED (I. NAMED KINDS).

There are few, if any, hardy border plants more easily raised from seed than Pentstemons, and from a garden point of view I have come to regard them as of great value. I have always pinned my faith to seedlings, and have previously been satisfied with the quality and variety of colours obtained by those means. Lately, however, some of my ideals have been somewhat ruthlessly shattered, for on inspecting a breadth of named kinds in a provincial nursery I find my seedling stock was poor in comparison, and I went away with somewhat mixed feelings. In the named kinds there were none without immense bells, towering spikes, and splendid colours. Some of these were very rich in tone, especially the darker reds and crimsons. These Pentstemons are mostly, it seems, of continental origin. Whether those with British names are home raised I did not learn, but they were in the minority. The following are a few which to me were the most striking: Cpt. Marchand,

André Lebon, Jean Mace, Dragon, Gabriel Barde, Commandant Larmy, Dr. Chantennesse, Miss Willmot, Lady Brodie, Lord Lister, Pres. Carnot, Talma, Phryne, Jane Misme, Jules Barbier, and Louis Grandeau. These take in a wide range of colour, which it is unnecessary to attempt to describe. Their great value is found not only in the grandeur of their colours and spikes, but the succession of flower which is maintained, and by cutting the early flowers others are produced for later displays. Pentstemons can be had in bloom in August, and will continue until frost stays their progress. Pentstemons look best planted in beds alone, either in separate colours or mixed together. In the flower garden they may very well take the place of Geraniums and Calceolarias, which need so much labour to carry them through the winter safely. In August and September beds of these would be extremely gay, and their cost not more in many instances than is paid for ordinary bedding plants in spring. W. S.

NOTES AND REPLIES.

Preserving Honesty.—Having repeatedly seen contradictory views of the value of Honesty seeds for cutting, I deem it well to give a very simple rule for rendering them useful for the above purpose. When the seeds are fully ripe pull up the plant and hang it up to dry thoroughly. On examining the seed-pods it will be found that they consist of three cuticles or skins. Remove the soiled ones on each side, and the centre one remains intact, displaying its silvery sheen in all its beauty.—A CONSTANT READER OF "GARDENING."

Decayed vegetable matter as manure.—Having seen in one of your late issues of "GARDENING" that this has been useful as manure in growing Celery and Strawberries, I have had a deep trench made, and a quantity of this sort of stuff removed from a yard pit and put into this plot, and covered over with the soil. What would you advise me to sow in this plot now, or should it be left fallow for some time?—MRS. DELANER.

[You ought to have put the material you speak of into a heap and mixed it with lime, and when decayed spread it on your vegetable quarters and dug it in. If you sow or plant anything in it the growth will be too gross.]

Late Dahlias.—It is somewhat out of the usual order of things to have Dahlias in full bloom at the end of the first week in November, as Dahlias are usually the first to tell us that frost has been in the air. Not only are the plants still alive, but growing luxuriantly, and sending up a crowd of buds to continue the flowering for some time, unless we get a decided change. I think the Cactus and single varieties have been even more richly coloured than they were in their usual season of flowering.—J. G., Gosport.

Carnations.—I have 24 Carnations planted in two rows, each plant about 12 inches from the next; one row is about 12 inches from a low brick wall, the other row is the same distance from a glass sliding; between this row and the Grass I have planted some yellow Crocuses, and between the other row and the wall some bulbs of Spanish Iris. The whole bed has a very cold and cheerless aspect at present, and I thought next May to plant some (five or six) Chrysanthemums between the rows of Carnations, removing some of these, if necessary, in order to brighten the bed in the following October and November. Will you please advise me if the Chrysanthemum will have any injurious effect upon the Carnations, and, if so, what would you advise me to plant to brighten the beds during these two months? Also, would the application of sea-sand do the Carnations good?—W. KING.

[The Chrysanthemums will be too vigorous and will injure the Carnations, more especially if you wish to increase your stock by layers next year. We would advise you to put in as a groundwork some Tufted Pansies, which will give you a display during the summer and well into the autumn. Chrysanthemums to do well must have a space of from 2½ feet to 3 feet between each plant. Muleh your Carnations well with rotten manure next spring or immediately you have put in the Pansies, if you decide to use them as we suggest.]

A beautiful balcony garden.—Those who have a taste for a garden often produce some fine pictures, and often under the most unfavourable conditions. This was brought most forcibly to my notice at the close of September, when visiting Camberley, Surrey. In the street near the railway station there are several shops, and over one of these I saw a beautifully-arranged balcony. It faces the street and is subjected to a large amount of dust. Boxes covered with cork in front were placed against the ornamental iron railing. In these boxes were good-sized plants of Ivy-leaved Pelargoniums. These were trained over the iron balustrade, and had grown freely, hanging down several feet. The kinds used were *Mme. Crousse* and *Souv. de Chas. Turner*. At equal distances were plants of scarlet

Geranium and Chrysanthemum *Halleri* alternately. Hanging below these were six wire-baskets filled with the same plants. All had been allowed to grow in a free way, showing no traces of tying. Such pictures show what can be done in seemingly unfavourable positions.—J. CROOK.

An autumn note from Cornwall.—What strikes one most in the garden this autumn is the greenness of the lawns and borders, and the lateness of autumn flowers. Pomponé Dahlias especially are indeed valuable, and have had a lengthened reign of splendour given to few flowers this season. Since they began to display their yellow, amber, orange, scarlet, and many fascinating combinations of tints, crowds of Japan Anemones have bloomed and faded, Lilies, white and rose (*L. speciosum*), have bloomed and passed away, Hollyhocks have bowed their stately heads, and Sweet Peas have gone from us. Almost the last Rose of summer has shed its scented petals, and the beautiful *Belladonna* Lilies have sprung leafless from the earth like Mushrooms and withered. The seasons seem playing at hide-and-seek this year. Here are spring flowers and summer blooms, deep blue Gentian (*G. acaulis*), and alpine Daisies looking up at glowing bushes of scarlet and yellow Cactus Dahlias, while they look down on winter Violets, double and single, and on opening Christmas Roses. Late white and pink *Cosmos*, the flowers of the latter a lovely lamp-light colour, are very useful for cutting. Tardy autumn Chrysanthemums will trespass on winter and make the flower season longer—unless the weather should suddenly change to one of our surprise frosts, then some of the later kinds will not open this year.—A. F. BROWN, Tywardreath, Cornwall, Nov. 10th.

Lilium auratum.—With reference to the recent note in "GARDENING ILLUSTRATED" respecting the decay of the bulbs of *Lilium auratum*, has picking off the flower-buds as soon as they appear the first year been tried? I have noticed this practice is recommended with other bulbs to increase their vigour. Is there any objection to applying the same system to *Lilium auratum*? It is evident with the majority of growers a sacrifice has to be made, and to lose the first lot of bloom would be the loss of two evils. *Esquimaux*.

[In the case of this species the removal of the flower-buds would avail nothing. This is usually resorted to owing to a general weakness of the bulb, and which in degree may be surmounted by the early removal of the buds. With the above *Lilium* there is no weakness whatever. On the other hand, the bulbs in the process of preparation for shipment to this country are denuded of their new crop of root fibres, and thereby bereft of the means of conveying food and sustenance to the bulb, and, in turn, of producing each year that new central core that contains the embryo flower-spike. Because these are not produced in the natural order, and because, by reason of heat, light, and moisture, the flowering spike of the previous year's growth has issued forth, nothing but a few scales or outer bulb leaves remain, and this remnant speedily collapses. The central core in this species flowers once and once only, a new flowering crown being formed each year in a natural way. By the process mentioned above the means of supply is entirely removed, hence no new flower centre is formed after the bulb reaches this country. The flower-spike we see in the year of planting is pre-existent, having been formed in the bulb and existing in embryo before the bulbs were harvested in Japan. It is this process which is ruptured by the donning of all roots, these including, unfortunately, the newly emitted crop of roots that issue with the maturing of the growth each year.—E. J.]

Helianthus Miss Mellish.—Some people object to this kind on account of its great height. It is a glorious autumn flower and has many recommendations, and no garden of any size can afford to be without it. I have it growing in the kitchen garden at the end of a border which has not been dug for four or five years. This has stood in this position all the time, and not had any attention beyond removing the dead foliage, and now the growth is from 5 feet to 6 feet high, and covered with its bright yellow flowers. It being a large mass the effect is striking at a distance. Although it thrives in such a position it enjoys a rich larder, and this I noted at the close of September, in a garden where it is used as a

background for other hardy plants. In the garden referred to the roots are lifted every spring, the four strongest being planted back and the others destroyed.—J. Crook.

CACTUS DAHLIAS—YELLOW VARIETIES.

This shade of colour is much appreciated in Cactus Dahlias, but up to the last year or two it was none too plentiful, and, maybe, there are faults in the newer ones that can only be remedied by time. Undoubtedly there has been great improvement recently. For a long time the best yellow was

LADY PENZANCE. This is clear and nice in

MRS. EDWARD MAWLEY.—Probably this is the finest yellow Cactus Dahlia we have. In the arrangement of the florets it is not so light as the last named, but in other respects it is an improvement. The colour is clear and rich. It has a splendid flower-stem, long and stout enough to hold the largest bloom. The flower itself is always double to the centre, and it can be grown to a huge size. A kind not yet in commerce is

IDA, and as exhibited is a very charming one. The colour is richer than seen in any one of those named, and it has a very long florot. It is not wise to recommend a variety unless one has grown it, but in this case we have a sort well worth noting. H. S.

submerge in a barrel of water for some days before using. The soil in which I grow them is composed of about two parts turfy loam, some well-rotted horse manure, leaf-mould, and sand. This I mix thoroughly and then roast by placing it in an old pan or server on the range until it becomes almost bone dry—this kills all worms, etc.; I then add a little wood ashes, made by burning hedge clippings, and which have small bits of charcoal in them. Having a pony I have arranged to convey its urine from the stall into a tank outside the stable, and occasionally I give all my plants a good soaking of it after fully diluting it and find they all like it. One of my Fuchsias, single, with white and purple flowers (not Rose of

A good yellow Cactus Dahlia—Mrs. J. J. Crowe.

our, but the fatal defect of this kind is that the blossoms hide themselves in the leaves. LADY TURNER, another old variety, is showy in the garden on account of its good flower-stem. The fault, however, of this is that the blossoms are heavy in appearance, yet the colour is bright and clear.

ETHEL is perfect in shape of bloom and habit of plant, being especially free flowering, but the colour is not decided or pleasing.

Mrs. J. J. CROWE (here figured) is indeed a striking yellow. The colour is good, and the shape of the flower elegant. It is comprised of long, narrow, ribbon-like florets, as seen in Japanese Chrysanthemums. It can be cultivated to produce blossoms 6 inches across, and much in depth; and when grown in the ordinary way still retains its characteristics. The flower-stem is long and wiry, thus holding the bloom erect. The variety is easy to grow.

Fuchsias falling.—I note the complaint of your correspondent, and am rather surprised, as, having a considerable number myself, my complaint is that they are doing too well. Perhaps he does not treat them properly; they do well with me (most of them at least) in the open air if well fed, but they don't do well in a draught; mine are of both the single and double sorts. Your correspondent may allow them to get too dry at the roots, in which case it is very hard to wet the ball of soil and roots. When they get too dry at the roots I place the pot in a bucket of tepid water (I never use cold water from the tap), entirely submerging the pot, and allow it to be so submerged until all the small bubbles which come up have disappeared. When they begin to grow early in the year, I feed them with diluted liquid-manure, composed of horse droppings and soot, both of which I place in the same bag and

Castile) has been in bloom almost continuously since Christmas, and has now hundreds of flowers on it.—A. MAZE.

Calceolaria amplexicaulis.—When planted out during the summer this species is, at a time that the others are nearly exhausted, just at its best, and for late flowering there are none to equal it. A quarter of a century ago this Calceolaria was far more common than it is nowadays. Being rather a tall grower led, we suppose, to its neglect, but now that the formally arranged flower beds are less popular than formerly, and in many places are to a great extent superseded by a mixed arrangement, it will be found very useful, and in late summer and early autumn the sulphur-yellow blossoms are very bright and cheerful. It is a free, vigorous grower, hardier than some of the garden varieties, and does not die off suddenly when at its best.

GARDEN PESTS AND FRIENDS.

ORCHARD PESTS AND HOW TO COMBAT THEM.

The following interesting notes, which, we hope, will be found useful to our readers, have been taken from a pamphlet on "Orchard and Bush-fruit Pests and how to Combat them," by Cecil Warburton, M.A., F.Z.S., Zoologist to the Royal Agricultural Society, and published by John Murray, Albemarle-street.

Certain Apple pests spend the winter in hiding-places in the bark of the trees. This is the case with the Codlin-moth, which hibernates as a chrysalis, and with the Apple-blossom-weevil, which passes the winter in the beetle form. A favourite shelter is a crack, roofed over by a flake of loose bark. It is advisable to destroy such shelter, and to expose these pests to the alternate frosts and thaws of winter by scraping the trunks, and removing, as far as possible, all the loose bark. The operation is still more successful if followed by a dressing of some suitable insecticide, well scrubbed into the cracks with a stiff brush during the winter. It is against the various insects which attack the leaves in spring and summer that washes and sprays are chiefly used. They cannot, of course, be applied while the trees are in blossom, for fear of destroying or keeping away the insects which are necessary to fertilise the flowers, but trees are sprayed before the blossom has opened or after the fruit has set.

There are two quite different classes of insecticides used for this purpose. One class is intended to kill the insect directly, while the other class brings about the destruction of the insect indirectly, by poisoning the leaves on which it is feeding. It is clear that this latter class is of no use against sucking insects, for the poison will not reach the sap on which they feed, but it is very effective against all the caterpillar tribe, which feed upon the substance of the leaf. It is also clear that it would be sheer waste to deluge a tree with a leaf-poisoning insecticide. It should be delivered as a fine spray, so that the poison may be sprinkled evenly over all the leaves.

It will be convenient to give at once the ingredients of a few of the most useful and readily prepared washes, so that they may be simply referred to under the various insect pests instead of being re-described in each case.

I.—LEAF-POISONING INSECTICIDES.

(a) Take half-a-pound of Paris (or emerald) green and stir well in a hundred gallons of water, adding a pound of lime. Distribute in a fine spray over the foliage, taking care to stir the mixture frequently, or the Paris-green will sink to the bottom.

N.B.—Paris-green is sold as a paste and as a powder. The paste is safer, not being so liable to blow about and be inhaled. If the powder is used, it should be pulverised before mixing, unless very fine in grain.

(b) Take six ounces of arsenate of soda and dissolve in a little water, pouring the solution into a hundred gallons of soft water. Also dissolve eighteen ounces of acetate of lead ("sugar of lead") in a little water, and pour the solution into the hundred gallons containing the arsenate of soda. Stir frequently during use, and deliver as a fine spray. A little soft-soap added to the mixture will help it to adhere to the leaves.

CAUTION.—The mixtures (a) and (b) are highly poisonous, and must not be left carelessly about, nor must the vessels in which they are mixed be used for other purposes without careful cleansing. Care must be taken not to inhale the arsenic powders. Fruit must not be sprayed within a few weeks of gathering.

II.—DIRECT INSECTICIDES.

(c) Dissolve half-a-pound of soft-soap in one gallon of soft water. Add this to two gallons of paraffin (kerosene) oil, and stir thoroughly. This gives a "kerosene emulsion," which must be diluted for use. The strength of the mixture will depend partly on the quality of the paraffin, and partly on the nature of the object sprayed—whether tender and delicate leaves, strong and vigorous foliage, or bare winter branches. An average strength for foliage will

be obtained by adding fifteen gallons of soft water to the three gallons of emulsion, but it is as well to test its effect on the leaves. For winter use a much stronger mixture is permissible, five to ten gallons of additional water being sufficient.

(d) Boil twelve pounds of Quassia-chips, and add the extract to a hundred gallons of water. Six or seven pounds of soft-soap may be advantageously added to the wash.

(e) A useful wash for winter use only, to kill hibernating insects and their eggs, or to clean tree-trunks smothered by Moss or Lichen, may be made thus: Dissolve separately in water one pound of caustic soda and one pound of crude potash. Mix the solutions, stirring up three-quarters of a pound of soft-soap in the mixture. Add sufficient water to make ten gallons. The best time for its application is the middle of February.

LEAF PESTS.

THE WINTER-MOTH.

Hosts of caterpillars may sometimes be found devouring the leaves and even the blossoms of orchard trees in the spring. Several different kinds will probably be present, but they all do harm in the same way, and as soon as they are observed in any numbers the trees should be sprayed with one of the mixtures (a) or (b). If most of the caterpillars are "loopers"—arching their backs as they crawl along—it may be concluded that the "Winter-moth" is at work. The "March-moth" and the "Mottled Umber" also have "looper" caterpillars, but as all three have practically the same life-history the particular species is of little importance. The important point in the life-history of the Winter-moth and its allies is this, that only the male moth can fly, the female having such ridiculously small and stunted wings that they are of no use to it. Indeed, the females would not be taken for moths at all by the ordinary observer, their fat, almost wingless bodies and long legs giving them quite a spider-like appearance. The caterpillars, at first so small as to be almost invisible, feed on the leaves till they are fully grown. Those of the Winter-moth are then about 1 inch in length, green, with narrow white lines along the sides, and with brown heads. They then leave the tree, usually letting themselves down by a thread, and crawl to some sheltered place, where they turn to chrysalids. From these chrysalids most of the moths come out in the following autumn, though some do not emerge till the winter is past. Now the female moths, after leaving the chrysalis, have to reach the twigs and buds of the fruit-trees in order to lay their eggs, and, as they cannot fly, they are obliged to crawl up the trunks. If by any means they can be prevented from doing this there will, of course, be no Winter-moth eggs on the trees to hatch out into caterpillars in the following spring. The plan of banding the trees with a sticky substance in the autumn does, to a large extent, prevent the ascent of the female moths, and greatly reduces the number of caterpillars in the following year. Bands of grease-proof paper or tied round the trunks some feet from the ground—high enough to be clear of any fruit-bushes below—and these are smeared with some adhesive substance which does not readily dry up, such as cart-grease or one of the numerous preparations in the market. The moths begin to come out in the middle of October, and continue to emerge all through the autumn, so that the trees should be banded by the second week in October, and the sticky material renewed as soon as it shows signs of drying up. Hundreds of wingless female moths are often caught upon a single band, together with several males, doubtless attracted by the presence of the other sex. The sticky matter should be renewed in the spring to intercept the March-moth and such of the Winter-moths as have passed the winter in the chrysalis stage.

PEAR AND CHERRY SAW-FLY (SLUG-WORMS).

The leaves of the Pear and Cherry, and sometimes of other fruit-trees, are occasionally found to be injured in a very characteristic manner by small slimy grubs, commonly called slug-worms. The upper surface of the leaves is entirely eaten away, the veins and the lower surface being left. The attack is gene-

rally noticed in September, but there is an earlier attack, usually not so serious, which takes place in June. The slug-worms are the grubs of the Pear saw-fly, a glossy black insect, not at all striking in appearance, about $\frac{1}{2}$ -inch in length. The ordinary observer would take it for a black fly, though in reality it does not belong to the Diptera or true flies, but to the Hymenoptera, the order which contains the bees and wasps. If examined carefully, it will be found to have four wings, like a bee. They are clear and transparent except for a darkish mark on the front wings. Another peculiarity, common to all the saw-flies, is the absence of a "waist," or constriction between the front and hind portions of the body. The saw-flies are so called because the females possess a remarkable saw apparatus with which they cut holes in leaves or wood for the reception of their eggs. The Pear saw-fly cuts a small hole in a Pear or Cherry-leaf, and inserts an egg, which is oval and white, and which takes about a week to hatch. The larva, which cause the early attacks are on the wing at the end of May, and in June their eggs hatch out into tiny grubs which are at first whitish, but soon become dark green and slimy, and much thicker in front than behind. They feed on the upper portion of the leaf, and, when many are present, give out a very disagreeable smell. By the beginning of July they are fully grown—about $\frac{1}{2}$ -inch in length—and now they drop to the ground, into which they burrow to a depth of about 2 inches, where they enclose themselves in small cartilaginous cocoons, from which the saw-flies come out at the end of July. It is these flies which cause the September attack on the Pear and Cherry-leaves, acting precisely like their parents. The grubs from the second brood, when fully fed (in September or October), seek the ground again, and the cocoons remain there till the flies come out in the following May.

REMEDY.—Lime is the substance which has been most successfully used against this pest when the caterpillars are feeding on the leaves. It may be used dry or as a wash. In the latter case, it is dusted over the leaves as a powder. The lime-wash is made by stirring a peck of lime and two pounds of soft-soap into three gallons of water. The dusting, or the spraying, must be repeated two or three times at short intervals, as the first application is thrown off by the grubs with the slime they exude. Early morning or evening is the best time for the operation, which should not be performed while the sun is powerful. The final dusting or spraying should be followed by a good washing-down with a garden engine.

PREVENTION.—The grubs spend the whole winter in cocoons in the ground beneath infected trees, and are thus at the mercy of the fruit-grower from October to May. The best treatment will depend on the nature of the orchard. If the ground is bare, the surface may be removed to a depth of 3 inches and burned or buried deeply. Simply digging up and exposing the cocoons to the inclemencies of the weather and to birds are of use. If Grass, a heavy dressing of kainit beneath the trees might have a good effect.

RED-SPIDER.

The leaves of Damson and Plum trees are subject to the attacks of this pest in hot, dry seasons. From their shrivelled and burnt appearance the disease is sometimes known as "fire-blast." Thousands of the microscopic creatures may be seen like a red dust under the leaves, amongst the network of fine silk threads which they spin. The "red-spider," which is in reality one of the spinning mites, spends the winter under stones or in crevices in wood—whether growing trunks or fencing timber. It comes out in the middle of May and attacks the leaves of Damson and Plum-trees and other plants (Hep, Currant, Gooseberry), sucking the sap and spinning a fine web which chokes up the leaf-pores. It lays eggs in the web, and multiplies rapidly, the young being at first six-legged, but afterwards eight-legged like their parents. It is only in especially dry weather that they are greatly destructive, their numbers being speedily reduced by rain.

TREATMENT.—Either of the washes (c) or (d) will be found useful against this pest. Sulphur, however, seems to be especially

INDOOR PLANTS.

DOUBLE BEGONIAS.

AMONG the double Begonias there is, I think, a greater variety of colour than is found in the single forms. In form, again, how varied are the double kinds, some of the flowers resembling a Roso, others a Hollyhock, while others, again, are like a Camellia. Others, again, consist of a large number of distinct florets, each in itself a perfectly double flower. Another valuable characteristic of the double Begonia is the duration of its blooms. Even under the best conditions the single flowers only last a few days, while the double flowers remain in good condition for weeks. Double Begonias have finer and more fibrous roots, and on this account the plants must be potted more firmly in a soil rather finer than the coarser-rooting single; require. The best compost is good

flower garden, as rain injures them but little. Give them a sheltered position. In using them for the open-air one great point is to have kinds in which the flowers are well thrown up above the leaves, taking also into consideration the shape, size, and absence of coarseness. T.

PLANTS FOR CONSERVATORY.

I HAVE a conservatory leading out of and attached to my drawing-room, the roof and front being glass and the two sides brick walls. There is no artificial heat but an oil-stove, lit at such times as is necessary to keep out the frost. Will you kindly advise on the following points: 1. A list of flowering plants which (like Campanula) hang and droop over the sides of the pots, to hide the pots and the edge of the shelf, and to be placed in the front row of the shelf. 2. A list of varieties of suitable plants which will afford a succession of flowers during the whole or a greater part of the year. I do not want a list of varieties, but merely a general list of species. 3. The most suitable climbing flowers to grow up the walls and over the roof. Would *Maréchal Niel* Rose, *Passion-flower*, *Clematis*, and *Lapageria rosea* do?—K.M., *Croydon*.

Fuchsias, Ivy and other Pelargoniums, Hydrangeas, Spiræas, and the like. Then in summer you may have quite a blaze of Begonias with some of the plants just named. Following these would be *Vallotas*, the early autumn *Crocuses*, *Liliums*, such as *longiflorum*, *Harrisii*, *L. speciosum* in variety, *L. croceum*, *L. umbellatum*. *Columbines* are very beautiful in early summer in pots, while the *Chimney Campanula*, *C. pyramidalis* in variety, and the fine *Canterbury Bells*, if well grown, would be very beautiful. For the autumn and early winter a selection of *Chrysanthemums* would be most suitable, and, with some well grown pot plants of *Michaelmas Daisies*, afford a gay and varied assortment. For climbing plants, *Clematis indivisa lobata*, and the forms of *C. lanuginosa*, with *Maréchal Niel* Rose, the *Passion-flower*, *Abutilon Golden Fleece*, white and red *Lapageria*, *Rose Catherine Mermel*, and *The Bride and Bridesmaid*, would provide a charming set. To work a conservatory of this kind satisfactorily, it would be needful to have a pit or frame to protect successive batches of plants and likewise another set of hardy plants in pans and pots that could be introduced at flowering time. The variety obtainable in this way is very considerable, and, in some instances, *Azalea mollis*, for example, the colours available are not obtainable in any other flowering subject. To get into proper working order is but a question of time and perseverance.]

NOTES AND REPLIES.

Agathæa cœlestis.—This is a valuable plant for late autumn decoration. When planted out it is apt to run away to leaf, the crop of flowers being correspondingly scanty, but kept in pots all through the summer the growth is sturdy, short jointed, and flowers are produced in quantity. We have such a limited choice of blue-flowered plants for conservatory decoration during the autumn and winter months that one ought not to neglect this *Agathæa*, which in a temperature of 50 degs. will keep on blooming. Like the *Paris Daisy*, there seems to be no limit to the amount of flowers it will yield, provided the culture is right. Cuttings put in in spring will make good specimens by September, keeping all the buds picked off till that month. From October onwards

the plants will make a nice show, and in spring also if encouraged with a little liquid-manure. Through the summer the plants should have a sunny position, so that the wood may be thoroughly hardened.

India-rubber plant.—I should be glad to know the proper season for transplanting an india-rubber plant which has become very pot-bound. Its height is 2 feet, and the diameter of the pot in which it is grown is 9 inches, and the height also 9 inches. I should also be glad to know what is the most suitable soil to plant it in.—Y. E. COMYAR-TYCKER.

[Shift it in the spring into a larger pot, using a compost of sandy loam, leaf-soil, and rotten manure, and be careful with the watering until the roots begin to work freely into the new soil.]

Galvanised pipes for heating.—Will you kindly say if pipes made of galvanised sheet iron will answer the same purpose as metal pipes for heating a house 6 feet square?—I intend using gas to heat water in small copper boiler.—PANDOX.

[We have no experience of galvanised iron pipes in heating with hot water, but we see not the least objection to them so far as the material itself is concerned. The pipes would of necessity be required to be of heavier metal than the ordinary galvanised sheets, otherwise the water constantly in them and the incessant wear by corrosion may speedily tell upon the lighter and thinner pipes.]

Primula obconica pisoneus.—This has led to much discussion at different times owing to its leaves, when handled, in some cases causing an irritation of the

A double-flowered Begonia.

[Trailing plants best suited to the above are: *Campanula isophylla alba* and *Mayii*, *C. fragilis*, *C. garganica* and *alba*, which include the best of trailing *Campanulas*. Other plants are: *Lysimachia nummularia*, *Saxifraga sarmentosa*, *Linnaria cymbalaria*. These are hardy. In summer you may add *Lophospermum scandens*, *Cobæa scandens*, *Tropæolum Lobbi*, and Ivy-leaved *Pelargoniums*, etc. Your list of plants for decoration will be rather sparse of flowering for some time in winter with only frost excluded. You may, however, indulge in *Christmas Roses* liberally, and certainly there is nothing finer for mid-winter bloom. The plants should be grown outside in pots, pans, or tubs in a shady place till required. Another favourite is the fragrant *Violet* in pots, and you may also in pans grow the *Tufted Pansies*, few things being more beautiful and free. In bulbous things for spring you may have *Squills*, *Chionodoxa*, *Cyclamen*, *Hoop Petticoat* and other *Narcissi*, *Hyacinths*, *Tulips*, *Muscari*, *Fritillarias*, *Spanish Irises*, etc. In shrubs you could have the berried *Aucubas*, also *Skimmias*, the golden *Euonymus* and *Retinospora*, etc. *Dielytra spectabilis*, *Doronicum*, *Iris nudicaulis* and *pumila* in variety, *I. germanica*, *Hepaticas*, *Anemones*, *Cinerarias*, herbaceous *Calceolarias*, *Clove* and other *Carnations*, *Tea* and *H.P. Roses* in pots.]

sound fibrous loam, with about half its bulk of sweet leaf-soil, some decayed hotbed manure, and rough, gritty material. When the roots have well occupied the soil an occasional dose of root-water or diluted guano will be very useful. Nothing, however, I have found is so good as diluted liquid-manure.

The plants should always be grown close to the glass, ventilating freely both day and night during favourable weather, with a slight shade from strong sun in the middle of the day. The double forms seldom attain their full development the first year, the plants being stronger, the blooms much larger, fuller, and more double the second year. Care must be taken in growing double Begonias not to overfeed, as this is liable to produce only single or partly-double blooms.

The double forms are also very useful in the

skin, while others who handle it are quite unaffected by it. In the spring I grew about 100 from seed, potted them, and they became good plants. I was not affected by poison. I repotted them. About two weeks after this I had small, irritating pustules on the wrist and face, with swelling of the eyelids, one eye being nearly closed. I consulted a physician. He pronounced it oenocela poisoning. He also said that other Primulas gave off this poison; not all, but some of them.—YAWCLIFF.

[We have handled plants of this and have felt no ill-effects. The irritation can easily be prevented by wearing gloves when working among the plants.]

CHRYSANTHEMUMS.

CHRYSANTHEMUMS AT THE AQUARIUM.

On Tuesday, Nov. 4, I visited the Aquarium to see the Chrysanthemum Show. I went with anticipations of great things; I left with a sense of disgusted repletion of big things. Anything more barbarous than the bloated blooms, which were displayed in all their round-bellied nudity, I never beheld. Chrysanthemum growers take infinite pains and display infinite skill in making God's most beautiful creations ugly. Even the single Chrysanthemums are being ruined by this insane passion for size. If you had an exhibition of the most beautiful and useful horses, would you prefer tun-bellied beasts of twenty hands? Are twenty-stone men the most beautiful of their species? But whatever the ugliness of the flowers, it was as nothing to the hideousness of their environment. Vulgarity, dirt, and painted squalor were the prevailing notes of the place. I left thanking Heaven that such an insult to the Abbey has been purchased by a religious body, and will no longer be associated with the most risky forms of acrobaticism, sensationalism, and other evils. The show was an object lesson as to the necessity for a building set apart to the service of horticulture.

HERBERT MILLINGTON.

FRUIT.

THE GREAT NORTH COUNTRY PEAR (JARGONELLE).

It is much to be desired that a race of Pears as good as this for north country climates could be raised. It is the best variety for Scotland and the north of England, and does well fifty miles north of Aberdeen as well as in many other parts of the country. For quality no Pear in its season can be compared to the Jargonelle. Certainly it is very liable to decay at the core when ripe, but August and September varieties have the same tendency. As the Jargonelle approaches ripeness great care should be taken in the gathering as soon as ready, and if "caught" in good condition the flavour is excellent. The best position for it is trained to the side of a house, or on the gable end of a building where there is room for extension, for it is impatient of the knife, and not until the tree has covered a considerable space and the spurs become old will it fruit freely. We know of a tree which, when trained to a wall and pruned in the usual way, never bore any fruit, but since the branches have been allowed to overtop the wall and grow away freely fine crops have been gathered annually.

As now is the time for planting fruit-trees, anyone having a gable end or house wall to cover cannot do better than plant a tree or two of Jargonelle, taking the precaution to well prepare the ground in the first place. T.

MAKING A PEACH-HOUSE.

(REPLY TO "H. G. W.")

The structure at your command should make an ideal cool Peach-house, and the lights being movable will all be in favour of the trees, and should be taken off as soon as the wood is thoroughly ripened and the leaves begin to fall. These should not be replaced until the buds are well advanced in spring, thus retarding the flowering period to as late a date as possible, as you have no artificial heat to keep out frost. First get the roof wired by screwing into each rafter galvanised supports for carrying the wire. These should be 15 inches long, with an eye for the wire to pass through. Three inches will be sufficient for the eye.

screw into the rafters, leaving 12 inches clear from the latter, and, surmising these are 3 inches from where the glass-lights are fixed, the trees, when trained, will be 15 inches from the glass, where the growths, as well as the fruit, will reap the benefit of the light and sun. These wires or rods should be 3/4 inch in diameter for Peach-training, and should run horizontally—that is, lengthways of the structure—and have a thread at one or both ends, so that a nut may be put on to tighten the same, or, better still, let the rods go right through both ends of the house and be tightened from the outside.

Next set about having a suitable border for the trees, after making sure efficient drainage is secured, 9 inches of broken brick-lats, rough at the bottom, the top 3 inches should be smaller, and, if considered necessary, a 3-inch drain-pipe should run along the entire length of the border a few inches below the drainage, and have a convenient fall, also outlet. Twenty inches to 24 inches of loamy soil, with a good percentage of lime and mortar-rubble, wood-ashes, and, if the loam is poor, a little Vine-

the best Strawberries for succession. In the answer to it I see no mention made of St. Joseph Strawberry. I got some small rooted runners of it last year from an advertisement in GARDENING ILLUSTRATED, and this month have gathered several dishes of ripe Strawberries from them in the open air. The last were gathered on October 22. The plants have still a good quantity of fruit on them, but probably there will not be sufficient sunshine to ripen the berries. They are of a good size and well flavoured. My garden is on a high hill, much exposed to the east, in the north of Ireland.—J. R. St. G.]

Planting fruit-trees.—I propose to plant 25 fruit-trees, composed of Apples, Pears, Plums, and Cherries, in meadow land, on light sandy soil. Should like to know what proportion of each kind, and the names of the best varieties of each.—ORCHARD.

[As you do not state in your query whether you propose planting standard, pyramid, or bush trees, I append two lists, the first consisting of varieties suitable to grow as standards, and the second of such sorts as will succeed either as bushes or pyramids. With regard to the proportion of each to plant, wo

Part of a Jargonelle Pear-tree in fruit. From a photograph sent by Mr. John Solan, Bilton House, Leasby, Northumberland.

manure added. It is unwise to make the border too rich, or the trees grow too strong. Far better feed from above as soon as a crop is secured. Make the soil quite firm and plant forthwith, and, assuming that the front wall is not more than 3 feet in height, fan-trained trees are the best to plant; if much above this, standard trees, having a clear stem of 3 feet, are better. After planting, merely make the growths secure from wind, the pruning and tying of same being deferred until early in February. You may plant three trees, the two end ones being 5 feet clear of the centre of these. Plant Hale's Early, Royal George, and either Violette Hative or Dymond Peaches, or, should Nectarines be preferred, Early Rivers', Lord Napier, Elruge, or Pitmaston Orange. A Rose may well be planted at each end. Climbing Niphotos, Pauline Labonte, Marie Van Houutte, L'Ideal, Mrs. John Laing, and Caroline Testout are all good kinds, and free, continuous bloomers.

Best Strawberries for succession.

—I read in "Notes and Replies" in GARDENING ILLUSTRATED of October 18, a query as to

think you could not do better than plant nine Apples, seeing that this fruit is generally in greatest demand, six each of Plums and Pears, and four of Cherries. List No. 1.—Apples: Beauty of Bath or Juneating, King of Pippins, Cox's Orange Pippin, Lord Suffield (if the latter cankers in your district substitute Lord Grosvenor for it), Warner's King, Cox's Pomona, Kentish Fillbasket, Land's Prince Albert, Wellington. Pears: Williams' Bon Chrétien, Beurré d'Amanlis, Pitmaston Duchess, Louise Bonne or Beurré Hardy, Emile d'Heyst, Josephino de Malines. Plums: Rivers' Early Prolific, Cox's Emperor, Jefferson, Victoria, Yellow Magnum Bonum, Pond's Seedling. If a Damson is desired, substitute Shropshire Prince Damson for Yellow Magnum Bonum. Cherries: Early Rivers', May Duke, Amorb Heart, Black Eagle. If a cooking Cherry is required substitute Morello for Black Eagle. All of the foregoing are constant and heavy croppers, and should succeed well on your light, sandy soil. List No. 2.—Apples: Lady Sudeley, King of Pippins, Ribston or Cox's Orange Pippin, Cox's Pomona, Lord Suffield or Lord Grosvenor (see remarks above), Warner's King, New Northern Greening,

Lane's Prince Albert, Beauty of Kent. *Pears*: Williams' Bon Chrétien or Souvenir du Congrès, Beurré d'Amanlis, Pitmaston, Marie Louise, Doyenné du Comice, Josephine de Malines. *Plums*: Rivers' Early Prolific, The Czar, Belle de Louvain, Denniston's Superb, Jefferson, Victoria, Monarch or Late Black Orleans. *Cherries*: Early Rivers', May Duke, Belle d'Orleans, Late Black Bigarreau. Morello may take the place of Belle d'Orleans should a cooking Cherry be required.]

GARDEN WORK.

Conservatory.—The Chrysanthemums are now at their best, and if the blooms have been fed up with stimulants to a large size, the ventilation must be carefully managed to keep them from damping, and there must be a little warmth in the pipes. The smaller, more naturally-grown blooms will stand more hardship, and last in condition longer. Those who grow large blooms will now be looking out for the strong, robust cuttings. They will strike best in small single pots in a frame where a little warmth can be had if required. I have rooted the cuttings in a frame placed in a cold-house; but if severe frost sets in before the rooting is completed the work is painfully slow, and it is better to have the command of warmth, even though it may not be necessary to use it. Some of the old varieties are lovely for cutting. We find ladies never seem tired of Lady Selborne, Wm. Holmes and Source d'Or, Rycroft Glory and Phœbus are useful for cutting. Many of the exhibition kinds are of no use for cutting, as these large-flowered varieties, when stopped several times to develop more flowers, and not disbudded much, are too weak in the neck, and will not stand erect without wire. Late varieties should be kept cool, and, of course, they will not be in the conservatory, but in the coolest house available. They will want a little warmth to develop the flowers, but whilst the buds are forming keep them cool and freely ventilated. Tree-Carnations are beautiful now for cutting, and their fragrance is delightful. Well-grown Violets in pots, with a few small pots of Grasses amongst them, are also useful. There is a graceful little *Carex* from Japan that does well in small pots, and is very pretty for mixing with such things as Violets, Cyclamens, and Roman Hyacinths. The last are now coming into bloom without much forcing. Primulas also are making pretty groups now, but such things are lost in a lofty house unless there are stands to fill in some part of the house. The watering must be in careful hands now, as damp arising from careless watering will do harm among the flowers, and too much fire-heat in such mild weather will not only be wasteful, but will exhaust the flowers, and cause them to fade before their time.

Stove.—Very often it is necessary to take some of the stove plants to the conservatory when in flower to assist in brightening it up, and if the stove is kept anything over 60 degs. at night, it is well to cool them down if possible in the intermediate-house if it can be done. We are all more or less the victims of circumstances, and have to make the best of things sometimes with limited means. To keep a large conservatory gay during winter, the stove and forcing-houses have to be drawn upon, and when it is possible to cool the plants down a little in an intermediate temperature the flowers last much longer. Some of the brightest plants in the stove now will be the Poinsettias, and these may be taken to the conservatory and formed into groups with fine-foliaged plants. A few plants of the variegated Japanese Grass (*Eulalia*) work in well with brightly coloured flowers. At present the conservatory is pretty well occupied with Chrysanthemums, but these will soon be thinned, and then the temperature can be raised a little, and stove plants of many kinds in flower will be more at home. I have moved large pots of Eucharis Lilies to the conservatory, where they have remained in condition for some time. The stove in the meantime may be filled up with Gardenias, Orchids, and other things moving on to the flowering stage. I have, sometimes, when the demand for Arm Lilies and Tea Roses has been urgent, moved a few

into the stove to push on the flowers. A gardener must be resourceful.

Pruning Peaches under glass.—Usually Peaches make abundance of wood under glass, and there is a good deal to cut away. As a rule, much of this thinning has been done during growth. A little more is generally done as soon as the fruit is gathered, and what remains to be done now is to ensure that the trellis is furnished with fruitful wood, cutting the surplus away. Every tree will, of course, be loosened from the trellis, with the exception of a few ties to the main branches to keep them in position whilst being operated upon. Under glass the Peach bears its crop on the young shoots. It will bear on spurs, but it is better to take the crop from the young wood only. Besides thinning out the young wood, a good knife-man will remove everything in the nature of spurs or excrescences that might harbour insects, and when the tree is pruned and washed with an insecticide the training may begin, and the branches should be so arranged that every part of the trellis is furnished with bearing wood. When the wood is well ripened, the only reason for shortening is to fit the shoot into its position. In the case of young trees with plenty of space to fill, the shoots may be left a good length. It is mainly a question of wood ripening. I have left the wood on young trees two or more feet long, only shortening back to where the wood is firm and ripe.

Ferns under glass.—If Maiden-hairs are getting shabby, or are losing fronds, it will be better to keep them drier at the root, and after a time cut down and let them rest in a cool house for a time. Towards the spring a new and vigorous growth will start away, and then the plants may be repotted or divided if more stock is required, though young plants raised from spores are more vigorous than old ones divided. Ferns should now have all the light possible, and enough water should be given to keep the growth active. Spores that were sown in autumn will now be ready for breaking up into small patches or colonies, which may be still further reduced when potted off. At present they will be planted in the usual small, shallow boxes, and be grown on shelves near the glass in a warm house. A suitable temperature for greenhouse Ferns now will be 50 degs. Tropical species will require 10 degs. to 15 degs. more. This refers to night temperatures only.

Window gardening.—There is a demand for dwarf Chrysanthemums in 5-inch or 6-inch pots for rooms and window-decoration. These plants are from late-struck cuttings of suitable kinds cut down early in June and stopped once after, and grown outside in an open situation, helped, when the pots are filled with roots, with liquid-manure. Such plants do well in window-boxes outside. The watering of plants in rooms must be done with judgment, giving enough to moisten all the soil when necessary, and then wait till the soil is dry before watering again. Use the sponge to keep the foliage clean.

Outdoor garden.—Remove all suckers and Brier shoots from recently-budded Roses. Cuttings of the Manetti and Brier should now be planted to raise stock for budding. Cuttings which are well rooted should be transplanted in rows 2½ feet to 3 feet apart to get established for budding next season. Standard Briers should be collected, and, after the roots are trimmed, planted in rows 3 feet apart. Plant firmly, and mulch with long manure. When planted, the tops should be cut to the right height, usually 3 feet to 4 feet. A few long, stout, straight stems may be planted for budding weeping Roses upon. Crimson Rambler makes a good weeper, and Paul's Carmine Pillar is very bright for the time it lasts. Aimée Vibert, Celine Forestier, and Cheshunt Hybrid are good on tall Briers. Lanrette Messiny, White Duchess, Cramoisi-Superieur, Fellenberg, and the old Red China make splendid groups against a background of shrubs, or, in fact, anywhere. These are a few of the plants which cannot very well be wrongly placed, because they will thrive anywhere in sheltered spots. Bamboos and Grasses may be grouped together. They appear at their best near water. Very pretty effects can be created by taking advantage of any sources of

water, such as a stream flowing near, to open it out and make positions for Water Lilies and other suitable plants. Turfing, planting, and earthwork generally are going on well now, and should be pushed forward whilst the weather is suitable.

Fruit garden.—Select cuttings of all kinds of bush fruits. Cut off close to a joint, and remove all buds but three at the upper end, and then plant firmly. The cuttings should not be less than 1 foot long. Good Gooseberries for market work are Crown Bob, Whitesmith, Keepsake, Industry, Lancashire Lad, and Whitesmith. Cuttings of most of the Codlin and a few other Apples cut off now in good-sized truncheons 3 feet or more long, and planted firmly in a shady border, will form roots during the winter. English Paradise-stocks may be planted now for working next season, either grafting or budding. If there should be any difficulty in obtaining these stocks, they can be obtained from most of the French nurseries where a speciality is made of fruit-tree stocks. Stout cuttings of Mulberries may be rooted if planted firmly in the shade and mulched to keep the soil moist and of equable temperature. The weather is very suitable for planting and pruning, and this work should proceed as fast as possible. The autumn is a good time to apply basic-slag and phosphate of lime to fruit-trees where such substances are required. More stimulating manures, should such be necessary, will be better given nearer the time when the fruits are swelling, but top-dressings of such things as old turf, wood-ashes, and a little old manure may be given at any time when available. Give surface dressings and keep the roots from running down. This is specially necessary for trees on dwarfing stocks.

Vegetable garden.—Forced Seakale is always appreciated, and though growth was continued late, the crowns are ripe enough for forcing now. There are several ways of doing this. Sometimes, where it is required in quantity, a good-sized hotbed may be made, and planted with crowns 4 inches or 5 inches apart. It may also be forced in deep boxes, covered at the top to exclude light. The boxes may stand under the stage in a warm house, and the Mushroom-house offers an easy means of keeping up a succession of good blanched Seakale, but it should be grown in a sweet, pure atmosphere, otherwise the Kale may have an earthy taste. The same remark applies to the forcing of Rhubarb, which usually comes on quickly in the Mushroom-house. Asparagus will soon start now in a genial temperature. Cauliflowers are abundant and good. There has been no frost to hurt, but all green crops are sappy, and if severe weather comes they will suffer. I should recommend that all late Broccoli be heeled over at once in the usual way, the stems being covered with earth. French Beans are not a very paying crop in winter, as things move so slowly, but a dwarf kind like Ne Plus Ultra may be planted in 6 inch pots and grown on shelves near the glass. It is not possible to do anything with Peas in heat, but dwarf early Peas sown now in pots and brought on quietly in a cool, light house, will come in early and provide a dish or two.

E. HODDY.

THE COMING WEEK'S WORK.

Extracts from a Garden Diary.

November 24th.—From this onwards we shall look closely after the Chrysanthemum cuttings. A strong cutting, as a rule, will make a strong plant, and though December or even January in some cases may be time enough to begin taking cuttings, it is never wise to miss a good cutting when one has the chance. Roman Hyacinths are now in bloom. They have had scarcely any forcing, but were potted early. Lily of the Valley is now coming forward in a warm-plot darkened.

November 25th.—Recently-planted trees are always staked, if they require it, as soon as planted, care being taken that the trees are not bound up too tightly. I believe the motion of the wind, if it does not disturb the roots, is beneficial. The finest Apples have been gathered from the bush trees on the English Paradise stock, but as the trees get older, the fruits are inferior. The remedy for this we

find is to feed on the surface, and encourage the roots to keep within reach of the solar heat. Beds are being filled with Tea Roses rather thickly to form masses.

November 26th.—Vaporised plant-houses to get rid of the flies. Great care is exercised that no plants infested with flies are taken into the conservatory. Special attention is being given to the planting of climbing or Rambler Roses in suitable positions, such as on arches. Framework is made of Larch-poles to represent a screen, or tall hedge. The bottom is filled in partly with China Roses and free-growing Teas. With such materials we have had no difficulty in filling in a screen 10 feet high in two years.

November 27th.—We have still a lot of Tomatoes in cool-houses. They ripen best on the plants, and we are reluctant to clear them out, but the houses are wanted for other things. Our heaviest cropping Tomato now is Laursen's No. 3, a very free setter. This, of course, accounts for its heavy crop, but it is not an early kind. Seakale and Rhubarb roots have been lifted ready for forcing. Made up another bed for Asparagus forcing. Mushroom-beds are always in course of preparation, as the house is kept filled up.

November 28th.—Made a new plantation of Gooseberries. We lately saw a large plantation of Gooseberries covered in permanently with wire netting, and for years they had been very successful. The Gooseberries were trained to wire trellises, and the fruits were fine and well flavoured. There was no trouble with birds, and no caterpillars. Started pot violets. The side pits are filled with leaves, which are fermenting a little, but there is not much heat, nor is much required at present. The pots are plunged in the leaf-beds.

November 29th.—Shifted a few of the larger Cinerarias into 6-inch pots. We are growing them very thinly on a coal-ash bed in a cool-house. Fires will be used when necessary, and the vaporiser used when the first green-fly is noticed. The pruning of fruit-trees is in progress, and we are anxious to get through this work before Christmas if possible. The bushes are pruned, and will be dressed with a mixture of soft-soap, lime, and soot before the birds usually begin their attack.

BEES.

Bee food.—Can you tell me how many seconds or minutes I ought to boil the sugar when making soft Candy for wintering Bees? I have had so many failures, and fear to try again this year, but find it is somewhat expensive to buy ready made. Should the syrup boil hard or gently? Even two minutes seem sometimes too much, and I get a hard toffee-like cake, which if my molars find tough, what must it be to the Bees' mandibles?—MYRANA.

[You will find that the Bees will easily consume your "hard toffee-like cake." Bee candy should be in this condition when properly made—when sticky and soft it has not been sufficiently boiled. After the syrup has been placed upon the fire it should be well-stirred, that all the sugar may be melted before boiling point is reached. As soon as the boiling commences the stirring should cease. The actual boiling should occupy two minutes, when the saucepan may be withdrawn from the fire and a little of the syrup dropped on to a cool surface. If it begins at once to set as that in a few seconds it will draw out as a thread, the mass is done enough. The pan should then be set in a trough of cold water. The stirring may now continue until the mass begins first to get dim in colour, and then to thicken to the consistency of thin porridge. It may then be poured into moulds, and should be sufficiently set within an hour to be ready for use. While they are still somewhat warm the cakes may be placed upon the tops of the frames, and covered with the quilts. Or frames may be filled with candy-cake and inserted in the hive at the sides of the cluster. In either position the Bees will consume the food as fast as they need it.—S. S. G.]

POULTRY.

Pullets' eggs for hatching (Longford).—You could not depend upon showy, healthy chickens from the eggs of pullets mated with a cockerel of this season, while breeding from related birds should be entirely avoided.

selecting eggs for hatching it is important that the parent birds are of mature age; if out under a year and a half old so much the better. A plan followed by some poultry breeders, and which is found to answer well, and to result in the production of strong, healthy chickens, is to run cocks in their second year with pullets, and cockerels with hens in their second and third year. It should be noted that in-breeding weakens the stamina of the birds, causes them to deteriorate in size, and the egg-producing power to become greatly reduced.—S. S. G.

BIRDS.

Java Sparrow (*F. l. l.*).—You did quite right in putting this bird to a speedy and painless death, as there was no chance of its recovery, for it was evidently suffering from paralysis, and as this progresses the patient becomes less able to use its legs or wings, and death occurs either from exhaustion or from difficulty in swallowing its food, resulting in choking. As you have found other birds showing somewhat similar symptoms, it maybe that your aviary is too exposed to the full rays of the summer sun. The direct action of the solar heat upon the birds for any length of time would be also likely to cause what is known as heat-apoplexy, or sunstroke. This, if not resulting in sudden death, would cause paralysis or serous apoplexy. Birds in an aviary under glass frequently suffer in this way, unless ample shade be provided. It would have been more satisfactory had you furnished particulars as to position of aviary, food, treatment, and so forth.—S. S. G.

The Goldfinch (*Fringilla carduelis*) (*S. F. P.*).—Orchards, shrubberies, groves, and copses are the usual summer resorts of this species. The nest is very frequently built in the branches of an old Moss-covered Apple-tree and is a masterpiece of bird architecture, being constructed of Moss, Lichens, and stalks of Grass, and lined with hair, wool, and Thistle-down, while the outside is so embellished with Lichens that it becomes difficult to distinguish it from the hrench upon which it is built. The eggs are pale greenish-blue, spotted and streaked at the larger end with purple and brown, and are usually five in number. The food of the Goldfinch consists of the seeds of the Thistle, Dandelion, Groundsel, etc.; the young being fed on seeds macerated in the crop. Three broods are reared in the breeding season, and by the beginning of October most of the young birds have attained their adult plumage and commence their migration southwards. A great many, however, remain in this country throughout the year, associating during the winter in small flocks, which perambulate the fields and hedges in search of food, visiting such plants as the Thistle, Teasel, and others which afford them subsistence. As a cage-bird the Goldfinch, from its beauty of plumage, its gracefulness, and its singular docility, is a great favourite. Very beautiful mule birds are produced by pairing a cock Goldfinch with a hen Canary. Young Goldfinches can be reared upon breadcrumbs soaked in milk, with a little scalded Rape and Poppy seed, but great care and attention are needed in order to rear them successfully. The adult birds should be fed upon Rape, Canary, and Thistle seeds, with a little Hemp, while for green food, Lettuce, Watercress, and Groundsel are all good at times, and are much relished. The difference between the sexes is very slight; in the hen, however, the crimson "blaze" does not extend above the eye, while the black feathers upon the head are edged with brown, and she is slightly smaller than the male.—S. S. G.

The Bullfinch (*Pyrrhula vulgaris*).—This handsome bird is common in the wooded districts of our island, and also frequents orchards, shrubberies, copses, and large gardens. It feeds largely upon Privet berries, Dock seeds, Plantains, etc., during the autumn and winter, but in early spring becomes very troublesome in gardens and orchards from its habit of destroying the young buds of fruit-trees. It also attacks the Syc, Whitethorn, Birch, and Larch in the same manner. The Bullfinch rears two broods in the season, and the nest, which is very closely constructed, and consists of

shallow platform of small sticks and fine roots, lined with horse-hair, is usually concealed in a dense bush, but sometimes is placed on the flat branch of a Pine or Silver Fir. There are generally five eggs, which are of a pale blue, speckled and streaked with purple at the larger end. The young do not acquire their bright plumage of the adult bird till after their first moult. The plumage of the hen is somewhat similar to that of the male, only that the bright red of the breast, and the grey of the back, are dull brown. As a cage-bird the Bullfinch is a great favourite, as it becomes not only tame and familiar, but very affectionate to those who feed it, and, although its natural song consists of but a low, plaintive undulation, it will, when brought up by hand, learn with great readiness the songs of other birds, and even distinct airs and tunes, if its instruction be persevered in. In confinement, the Bullfinch should be fed upon black Rape-seed, scalded, to which may be added Canary-seed in small quantities, with occasionally a stalk of ripe Plantain-seed, a few Privet berries, a little plain biscuit, a piece of Apple or boiled Carrot, and a small quantity of Watercress: the greatest treat, however, is a few twigs of some fruit-tree, from which the bird will pick the buds with great relish. It is not safe to supply Hemp-seed in quantity, as this has a tendency to darken the plumage; in fact, some Bullfinches have been known to become quite black from feeding too freely upon this seed. From twelve to twenty seeds a day may, however, be given with safety. These birds are very susceptible to the influence of heat, which affects them injuriously. They should, therefore, never be kept in a high artificial temperature.—S. S. G.

Feeding kittens (*H. B. D. P.*).—The feeding of your kittens is greatly at fault. Milk only, with a little bread soaked in it, is not a sufficiently nourishing diet for young, growing cats. They should have a little lean, cooked mutton or beef once a day, to which some boiled green vegetables should be added two or three times a week, the greens being chopped up with the meat. This should form the mid-day meal. For breakfast they may have porridge or brown bread and milk, while for supper, bread soaked in good gravy would prove beneficial. As a change of diet they may have boiled fish once or twice a week. A few small pieces of slightly-cooked liver may also be given now and then. Boiled rice and gravy is good for them. Grass forms a natural aperient, and should be provided where cats have not access to it out-of-doors. They prefer the larger and coarser kinds of Grass. Clean, fresh water should always be available. Young kittens just removed from their mother may have any of the manufactured infant's food mixed with warm milk. Your kittens are at an age when they require particular care and attention, and to help them through this critical stage they may require a diet of a still more nourishing character, such as shrodded, raw, lean meat or meat extract, or an egg beat up in milk and sweetened.—S. S. G.

LAW AND CUSTOM.

Income tax.—Thanks for your reply, on page 104, to my question. You were right—the demand was under schedule A. The property is not mortgaged.—NORMAN.

[My reply was slightly misleading. If an assessment to income tax is once made it may be enforced unless rectified on appeal, and so, although the refund of the wrongful assessment might be obtained on application, it will be better for you to appeal to the commissioners and have the matter put right, or payment may be enforced from the occupier of the plot, and he may have some trouble to secure repayment. At one time, the owner of premises let to a tenant, and assessed in the tenant's name, was in a doubtful position as to appeal, but that matter was put right by the Finance Act of 1896. Probably if you communicated with the surveyor of taxes, stating all the facts, he would rectify the matter without putting you to the trouble of an appeal.—K. C. T.]

The Prize Winners this week are: 1, Miss Mabel Gaisford, The Grove, Dunboyne, for Rose Mme. Alfred Carriere; 2, Rev. G. S. Whitehead, Bedala, Yorks, for Yellow Tree.

CORRESPONDENCE.

Questions.—Queries and answers are inserted in GARDENING free of charge if correspondents follow these rules: All communications should be clearly and concisely written on one side of the paper only, and addressed to the Editor of GARDENING, 17, Pall Mall, London, E.C. The name and address of the sender are required in addition to any designation he may desire to be used in the paper. When more than one query is sent, each should be on a separate piece of paper, and not more than three queries should be sent at a time. Correspondents should bear in mind that, as GARDENING has to be sent to press some time in advance of date, queries cannot always be replied to in the issue immediately following the receipt of their communication. We do not reply to queries by post.

Naming fruit.—Readers who desire our help in naming fruit should bear in mind that several specimens in different stages of colour and size of the same kind greatly assist in its determination. We have received from several correspondents single specimens of fruits for naming, these in many cases being unripe and otherwise poor. The difference between varieties of fruits are, in many cases, so trifling that it is necessary that three specimens of each kind should be sent. We can undertake to name only four varieties at a time, and these only when the above directions are observed.

PLANTS AND FLOWERS.

Dahlia from seed (S. L. S.).—Gather the seed at once, dry and clean, and put away in a drawer until next February, when sow in heat in boxes or pots. When ready, pot off the seedlings singly into small pots. Pot on as may be necessary, finally having them in 48-pots, and then plant out in good soil at the end of May.

Pelargonium cuttings (W. King).—Put these on a shelf in the greenhouse and water carefully during the winter, potting off singly into small pots early next March, or if you can command a little heat, in February. If you have no greenhouse you can stand them in a window in a room, taking care that the frost does not reach them, and in the spring pot off singly.

Lily of the Valley (G. B.).—These, if lifted in clumps, may be torn asunder by the hand, or if too dense for this a strong knife may be used. In these plants it is not the roots that form the strong connecting mass, but the stoloniferous stem or shoots just below the surface. By severing these the strongest crowns are obtainable apart, and these are the ones for flowering next year. The thinner growth crowns will succeed them in their flowering a year later.

Clematis Jackman (P. M. Dwyer).—This is a large-flowered autumn and summer bloomer, flowering on the young or summer shoots. The stem, therefore, in pruning should be developed vigorous young shoots, which is done by cutting the summer growth back each season as soon as frost has cut down the plants—say, in November—to within about 6 inches of the soil. The surface should then be mulched with some good rotten manure.

To distinguish Brier from Rose foliage (Rudolf).—The common hedge briars are quite distinct from cultivated Roses in leaf and flower. The leaves of the Brier are about one half the size of the majority of those of Roses. Each leaf is of a long lance shape, prettily serrated, wood light green and covered with numerous brown prickles. The Manetti, another foster stock for Roses, has very light green leaves and reddish prickles. If the shoots you send spring from the plant just below the graft, then undoubtedly they are those of the Manetti, on which your Roses are evidently worked.

Pruning newly planted Roses (S. W.).—Next March will be the best month in which to prune the Roses you have just planted. It is advisable to prune such Roses rather severely the first season; by this we mean cutting them well down to the ground. This induces new growth from the base. In the case of the climbing varieties, one shoot should be selected and cut hard back quite to the ground each year, thus ensuring a constant supply of new growth from the bottom. In this way the measure amount of shoots in the ground, which often spoils the appearance of an otherwise good specimen, is avoided.

Pruning H.P. Roses (Inquirer, Kent).—Two of the varieties you mention—'Irish Broom' and Mrs. J. Laing—being vigorous growers, must not be pruned too severely. The long growths made this year should be shortened back when the time arrives (month of March) to about 8 inches or 12 inches from the base. In some cases, in order to maintain an even balance, it is well to retain some growths on each plant 15 inches to 18 inches long. Lateral growths from last year's wood should be cut to two or three eyes, and all very small wood and any that appears weak should be entirely removed.

California Irises (G. J. Padbury).—The kinds referred to may possibly not be in general cultivation, and possibly I. tenuis is not in cultivation, or, if so, quite rare. The others are interesting rather. I. tenax produces solitary flowers of a lilac-purple, and is notable for the great strength of the fibre obtained from its leaves, which are rarely more than two. It is of slender growth, and should be grown in a warm position in loamy soil. The plant is about 12 inches high. I. hexagona is a strong-growing kind from the Southern United States, often reaching 3 feet or 4 feet high, flowers pale to deep lilac. The stems are much forked and furnished with long and broad leaves. It is best to grow it in a south border, where a deep sandy loam is at command.

Carnations from cuttings (H. R.).—The method recommended by me in a recent issue is quite seasonable now and to the end of the year. There is no need for a frame, and in not a few instances, and of the more hardy sorts in particular, the cuttings are best in the open, apparently delighting in the abundant heavy dew and uniform moisture at this season of the year. A great point is that of securing a good heel to each piece, and, secondly, of inserting the cutting, so-called, quite firmly and right up to the leafy portion. Such cuttings root readily, and are fit to plant in permanent places by the end of March. Indeed, a handful clipped off from a

In September, 1901, were well rooted two months later, and if amateurs would try for themselves, they would be able to put out six plants for every one at the present time. The system is so simple, yet so good and reliable, that no one need be at all short of good bushy plants for planting out, and if once tried there is every possibility of its being continued.—E. J.

Flower border (Irish).—We do not grasp your meaning. Your statement that the branches of an Apple-tree so much overhang the border that ordinary subjects are a failure would suggest general poorness of the soil. Hence we fail to see why you think of planting Laurels, the more so as the "border" commands a prominent position in front of house. You say nothing as to length of border, or whether any portion is more favourably placed. On the face of it, the Apple-tree appears the offender, and if it cannot be removed, it may certainly be both pruned and thinned of some of its branches that the plants named may do better. Unless this can be done, we fear you will not realise the brilliant effect in summer which you require. These summer hardy plants that do quite well in shady places if the soil be good, and we imagine the soil is at fault somewhat. Therefore, to attempt shrubs would only end in failure. Cannot you give us some more definite particulars, especially as regards the class of soil, its depth, and the extent of the border? If the Apple-trees are valuable, the idea of a Laurel hedge at their base would be ruinous.

TREES AND SHRUBS.

Escallonia, propagating (W. King).—This is easily increased from cuttings of the young, rather firm shoots, put into sandy soil with a little peat and road-grit, under a handlight in summer, or you can use younger shoots, putting them into pots and placing under a bell-glass in the greenhouse.

Pruning common white Jasmine (A. Water).—This is evidently a case of over-pruning, thus causing a too vigorous growth. This Jasmine does not, as a rule, require much pruning, but when it does, the summer or flowering plant, being cut quite always be done after the flowering season is over. Simply cut out the old wood and cut back the more vigorous shoots.

The Burmast Oak (Quercus sessiliflora) (E. C.).—This is often included with Q. pedunculata in the British Oak—but is distinct, from a planter's point of view, not being so long lived or quite so noble a tree. It has a straighter and more cylindrical stem and form of tree even than the common Oak, has a deeper green, denser foliage, and gives more covert. The leaves, too, are a little longer than those of our native Oak, these sometimes in mild winters remaining on the tree till the others come. It also differs from Q. pedunculata in that it will thrive on gravelly soils, while the common Oak is best on heavy soils. The wood, too, of the Burmast Oak is less tough and less resisting than that of the common Oak, it having a straighter fibre and finer grain.

Azalea mollis in pots (South Stafford).—If grown and flowered altogether in pots the plants will need careful potting in a soil principally composed of sandy peat, and when the flowering season is over they must not be at once exposed to cold, cutting winds, but gradually hardened off. If this is well done the whole of the leaves will be retained in a good condition, and when all danger from frost is over the plants may be plunged out-of-doors in an open spot. A bed of Cocoa-nut-fibre-refuse is the best plunging material, as it tends to keep the roots in a uniform state of moisture. During the summer the plants must be carefully watered, and occasionally a little weak liquid-manure given. In this way the flower-buds will set quite freely, and the blossoms on established plants remain fresh for a longer period than those that are just lifted from the open ground and taken into the greenhouse. Planting out and forcing in alternate years are also practised with advantage by many, but in either case the principal road to success is to see that the plants are properly supplied with water throughout the summer, and are not crowded up, as a free circulation of air is very necessary to the formation of flower-buds.

FRUIT.

Raspberries (Raspbery).—Cut out all of the present year's fruiting canes from your Raspberry stools, as these are now useless, leaving to each stool or clump from four to five stout young canes, and cutting out all the weak ones also. Tie these to a strong stake. See reply to "C. B." in our issue of Nov. 8, p. 478, re "Manuring Raspberries." It is a mistake to plant such things as Cabbages and Brussels Sprouts among Strawberries, as these hinder the development of the crowns and nitrate against fruit-bearing next year.

Planting bush Apple-trees (M. F.).—We could have better judged as to the merits of planting bush Apple-trees between rows of standard Apples had we been informed as to the width apart of the standard rows. To plant bush trees between, if the standard trees are large, they should be fully 30 feet apart. However, your best varieties for bush planting are the Paradise and Cox's Orange dessert quince, which will be Allington Pippin, Cox's Orange Pippin, St. Edmund's Pippin, Cockle Pippin, and Sturmer Pippin. These all keep late if well ripened and properly stored. They are ready in the order given. A very good cropping and not at all a strong-growing cooking Apple is Stirling Castle; so also is the earlier Maxx Codlin. Plant bush-trees in their rows from 10 feet to 12 feet apart.

Paraffin emulsion (E. Hendy).—This can easily be made in the following way: Mix 1 quart of soft-soap in 2 quarts of boiling water, while hot add 1 pint of paraffin oil, churn this well up with a syringe for 15 minutes then dilute ten or twelve times with water, and add a quarter of a pint of turpentine. When applying the mixture it is well to have two syringes in use, one with which one person can apply the mixture to the fruit-trees, while another person can keep the mixture well stirred up to prevent the paraffin coming to the surface.

Training espalier Apple-trees (Balmombe).—The training of espalier-trees is a slow work, but with patience is later well repaid. You do not tell us the height of the stocks you have grafted with Apples, but if they are low down, as they should be, you will have to cut back your summer graft growths to about 6 inches in length. Then, next spring, three buds should break out,

the top one to be taken upright as leader, the two others, one on each side, taken out and tied laterally to form the lower tiers of branches. These shoots should make each some 3-foot growth. The leader would in the following winter have to be cut back to 12 inches, taking three shoots and treating those as before, and so on each year until the tree was furnished with side branches. The side shoots would have to be cut back to one half their length, and a single leader from each taken on and cut back one half each year, until the side branches were of proper length. The varieties you name all make good espaliers. The clay and ties should have been removed long since.

VEGETABLES.

Raising Tomatoes (Pandon).—For the raising of Tomato seeds in January a temperature of 68 degs. or 70 degs. is required; the first will do quite well if steadily maintained. To do this there should be two pipes, each of 4-inch diameter, arranged along the front, the side, and the back, or the front and the two sides if more convenient. Possibly you could take pipes in at one corner, traversing the front, the side, the back, and along the other side, and then conduct the return pipe to the starting place. If the house can be encompassed in this way, pipes of 3-inch diameter would suffice. Beyond this it is more a question of keeping up the heat in the pipes. With respect to moisture, the seeds require very little at this stage. In fact, much moisture is the greatest enemy, so many seedlings damping off. During the two first months of the year floors should not require damping more than once daily, and at no time should it be requisite to damp down thrice in a day for this crop.

SHORT REPLIES.

A. E.—Such as Phloxes, Anemone japonica, Michauxia Daicies, Sunflowers—in fact, any hardy plants—would do well in such a position. Plant at once, if you can, leaving spaces for some of the early-flowering Chrysanthemums, Gladioli, etc.—Y. F. Z.—No, you cannot do as you suggest. Under the circumstances, the only thing which can be done is to cut down and grub up the tree.—A. H.—We have the Ampelopsis growing on a painted surface, and see no reason why you should not do the same.—M. C. Dighton.—We do not quite understand you, sir. If so, such are injurious to plants.—L. B. W.—We know of no book dealing with the subject you refer to.—Dr. Harlock.—See reply to "Black Currant," re "Black Currant-mite," in our issue of Nov. 8, p. 477. Unfortunately, your bushes have been attacked by the pest.—Tabitha.—Your plant is eaten up with thrips. To cure this you must syringe with Tobacco-water or fumigate the house, if possible, in which it is growing. Try it on a warm wall in the open.—A Subscriber to "Gardening."—Kindly send three specimens, and then we will try and help you.—Early Bird.—See reply to "R. L. Routh," re "Worms in lawn," in our issue of Nov. 15, p. 492.—Pampas.—We have never heard of the Pampas Grass being grown in tubs, and doubt if it would do thus, as it is too strong-growing. It will do well in you in the open.—Z. R.—The Fuchsia you refer to will not stand out-of-doors in the winter. They are only used for the flower garden in summer.—J. Palmer.—Try E. Veitch and Sons, Exeter, who will no doubt be able to procure what you want.—Lisa.—1, Your Apples ought to keep well in the cellar. Simply lay them on the shelves, using neither sawdust nor bran. 2, Sprinkle some lime between the lines of Strawberries, and then when the time comes you can straw down the beds. 3, Impossible to say unless you tell us something of your soil—i.e., whether heavy or light.—W. A. G., Kent.—Kindly say what Jessamine you refer to. Leave your Roses till the spring, say March.—A. M. T.—Evidently one of the Maples (Acer), but why send such dried-up leaves!

NAMES OF PLANTS AND FRUITS.

Names of plants.—Lilla Rome.—Your plant is the common Spurry (Spergularia arvensis).—M. A. Lyter.—Fruit of Pyrus (Cydonia) japonica, said to make a very fine preserve.—Adam.—1, Saxifraga Fortunei; 2, Viola heterophylla variegata, quite hardy.—Caution.—I've left that you send is the true Hedera digitata (H. E. palmata).—John Currie.—3, Epimedium, send in flower; 4, Aster cordifolius var. R. N.—1, Escallonia macrotha; 2, Salvia farinacea; 3, Helianthus autumnale crispus; 4, Rafflesia.—1, Chrysanthemum Horace Martia; 2, Marie Stasse; 3, Roi des Precoques; 4, Specimen insufficient.—M. M. Eaton.—The Bottle-brush plant (Menziesia floribunda).—E. C.—Impossible to name without account; 3 and 4, Specimens insufficient.—W. A. G., Kent.—Kindly send specimens in bloom.

Names of fruits.—Walter M. Simpson.—(1) Not identified; fruit insufficient; 2, Probably Brown Beurré.—No name or address.—Apple Yorkshire Greening.—Thompson Moore.—Apple Yorkshire Greening.—Ester, Bark.—Pears: 1 and 3, Broom Park; 2, Marechal du Centre; 4, Pitmaston Duchess; 5, Josephine de Malines.—J. B. Hayland, Hereford.—1, Cellini Pippin; 3, Burdock; 4, Seeding; 3, Lord Hindlip; 4, Blenheim Orange; 5, and the Dutch Mignonne; 7, Beauty of Hante; 8, King of the Pippins.—J. R. Hinchley.—1, Apple Fern's Pippin; 2, Not recognised.

Book received.—"The Narcissus at the Ashpodes." By A. Wilson, M.A. Dunedin: R. J. Satt and Co.

The Royal Gardeners' Orphan Fund.—The Right Honourable the Earl Carrington has kindly consented to preside at the next anniversary festival of this charity, which will take place at the Hotel Cecil on Tuesday, May 6th, 1903.

United Horticultural Benefit and Provident Society.—The usual monthly committee meeting of this society was held at the Caledonian Hotel, Adelphi Terrace, Strand, on Monday evening, 10th Nov. 1902. Mr. H. Curtis in the chair. Present: Messrs. J. B. Hayland, Seeding, 3, Lord Hindlip, 4, Blenheim Orange, 5, and the Dutch Mignonne; 7, Beauty of Hante; 8, King of the Pippins.—J. R. Hinchley.—1, Apple Fern's Pippin; 2, Not recognised.

does more harm than good. Probably it would sell for enough to pay the cost of the taking down. Too many trees harbour birds. Destroy nests in the spring, and that will help to keep them down. Their company is often very dearly purchased when they do so much harm to crops.

THREE GOOD PEARS.

For use during the latter half of October and early November, *Beurré Superfin*, *Marie Louise*, and *Pitmaston* form a trio that please most connoisseurs, the first, perhaps, best of the three. In most years all prove good with me, though it is not on every soil *Pitmaston* is found satisfactory; this is to be regretted, as it is much the noblest fruit, and makes a very telling dish for exhibition or the dessert-table, while for market it always fetches a good price.

far and near to be *par excellence*, and does equally well on a west or east aspect. This is the season for planting, procuring trees two years from the bud and worked on the Pear. They may bear earlier on the Quince, but some varieties make but little growth, and never seem able to fill their allotted space, even when annually top-dressed with a good compost.

EAST DEVON.

[With the above note we received some very handsome fruits of the varieties named. *Beurré Superfin* was excellent in every way—in fact, the finest samples we have seen of this Pear. The *Pitmaston* was very large, as also was *Marie Louise*.—Ed.]

NOTES AND REPLIES.

Protecting Vine borders.—Where the Vines carrying the latest bunches are root-

is no necessity for covering these with either manure, leaves, or other material, as they would be all the better exposed to the sweetening influences of frosts, winds, sunshine, and rain. All exposed stems, whether or not forcing is to be resorted to, should be carefully protected with hay bands, or else be enclosed in boxes large enough to hold a good packing of dry sawdust. Frosts do not injure the stems while the Vines are at rest, but would quickly rupture the sap vessels directly the sap commences to flow. If done now there will then be no risks run.

Second crops of Plums.—The season now near its close has been more than usually erratic as regards the weather, but, on the whole, it has been favourable for gardening. Fruit crops were in nearly all cases below the average, both in quantity and quality, for the very low temperature in May and June destroyed the hopes of a heavy crop, which in the early part of spring looked like a certainty. The young fruits that looked like setting freely continued to drop off, until the only trees that were really well laden were the Pears, which with me perfected a heavy crop of fine clear fruit. All kinds of stone fruits, especially Cherries and Plums, dropped off until only a sprinkling was left. Many trees bloomed a second time and set a good many fruits at midsummer, with the result that little, green, half-grown fruits were no novelty this year when the others were ripe. I gathered half a gallon from one tree in November.

Top-dressing Strawberries.—Plants of more than one or two seasons' growth greatly benefited at this season of the year by a good top-dressing. This has especial reference to light or thin soils, or where the plants are apt to suffer much from drought. It may have been noticed that the older plants are the first to collapse during a dry season. To obviate this or to lessen it considerably, a top-dressing of suitable compost will be found of great benefit, this assisting in the formation of surface roots near the collar of the plants. It will also have been observed that as Strawberries grow old, hard woolly stems are formed, and it is these which are the first to collapse under a heavy strain of bright sunshine and drought. In very many cases the plants quickly flag, and when this is the case, the hopes of securing a crop of fruit are small. Before adding the top-dressing the plants should be very lightly pricked over, but not deep enough to disturb any of the roots. The dressing of soot should be first applied. The top-dressing should consist of burned garden refuse, some well-decayed manure, and any other soil that may be at hand. Old Manure and Cucumber soil, surface soil from Vine borders, or anything similar is what is needed, the whole being mixed and spread over the surface, working it also well in about the crowns. If a depth of 2 inches or thereabouts could be given, it would be both labour and material well spent.

Apple, London or Five-crowned Pippin, is so called from the five prominent angles or ribs which originate on the sides of the fruit and terminate at the eye. Although a very old variety, it is still one of the best for late use, and I knew of no Apple to surpass it for the dessert in the months of March and April. Roundish in shape, somewhat flattened, and having the ribs or angles already mentioned, skin clear yellow when ripe, with beautiful red flush on the exposed side; eye small and closed; flesh yellowish-white, tender, juicy, and pleasantly flavoured, is a somewhat brief description of a typical specimen. As a cropper it is first-rate, and one of the few varieties that has really yielded well this season. In a cool store it will keep good until June, but is at its best when used any time between January and April. In addition to its being a good table Apple, it is excellent when either boiled or baked. It may be grown either as an orchard standard or as a bush tree with excellent results. As a standard, the habit of growth is rather pyramidal, and the branches are inclined to be pendulous, so that the lowermost ones need to be kept shortened back to keep them out of the reach of stock. Those about to plant should certainly include London Pippin in their list if they have not done so.—A. W.

Pear *Beurré Superfin*.

Unfortunately, Pears, when ripe, do not keep any length of time; if they did the fruit would be much more valuable. *Beurré Superfin* does well as a cordou trained around an iron trellis in the open in the West of England, though the finest specimens are generally had from a wall facing west. I suppose it is a matter of taste as to which form the Pear should be trained in when planted against walls, though my experience is that much finer fruit can be had from fan-trained trees than from those trained horizontally. Not only this, a wall, 12 feet or 14 feet in height, is much sooner covered than when horizontal training is the rule, and if the trees make too strong a growth, root-pruning or entire replanting will rectify this evil, if carried out every few years until good crops are secured.

ing principally in outside borders, these latter ought to be covered with either shutters, strips of galvanised iron, spare lights, or other material that will ward off heavy rains. Grapes not keeping well when the borders are badly saturated. Vines that are to be started early ought to have their roots solely or principally inside the house, but if the front walls are arched or the roots have access to an outside border, that is where they will mostly be found. Till such time, therefore, as mild hotbeds are formed on these outside borders, they ought to be rather heavily covered with fresh leaves kept in position by either a straw thatching, boards, or shutters, this being done to prevent an undue lowering of the temperature. In the case of Vines that will not be started much before the end of February, there

PLANTS AND FLOWERS.

OUTDOOR PLANTS.

LILIUM LONGIFLORUM IN SOUTH DEVON.

The small measure of success that attends the efforts to grow *Lilium longiflorum* and its

section, culminating in the Indian *Lilium giganteum*, that takes some seven years to reach flowering size.

Feeling sure that "somehow" the culture was also to blame, I tried the Lilies in the way shown in the photograph, and I think I have succeeded; at any rate, the Lilies go on year after year with a most satisfactory increase. They were planted in irregular groups of from three to six bulbs two and three years ago.

bulbs; in front of them there is a long row of some hundred *Incarvillea Delavayi*, fringed by white Japanese Pinks. The border is about 100 feet long. It has a quaint little fence of Bamboo on the path side, 30 inches high, with tall Bamboos every 1 foot for Clematis to grow on, a thing of the future, as mine is not a Clematis soil, lacking lime; it is new red sandstone, very warm and dry, yet fertile. The Lilies are planted in black peat, and every winter have about 2 inches deep of sifted leaf-mould spread over them to nourish them and protect from spring frosts. The border has been widened this autumn to allow 100 *L. Alexandria* to be planted between the *Incarvilleas* and Pinks. These Lilies flowered splendidly with me this summer in another part of the Japanese garden, but were so placed that they turned their flowers away from the path to the sun, so did not show to advantage.

Whenever a bulb was found to "break up," the young bulbs were planted in a trench filled with peat in the kitchen garden. Some put in two years ago threw up dwarf flower-stems this summer, with one bloom; very creditable, considering they were not nearly so large as a lady's thimble when put in. One interesting fact, these baby bulbs do not show above ground (I mean, do not throw up foliage) till they send up flower-stems. Just a few have one little leaf, like a small "blind" Tulip leaf, but the majority have not even this, though they steadily grow at the root.

Dartlish, S. Devon. A. BAYLTON.

HARDY SCILLAS.

In the early spring few bulbs are more valuable in the garden than the Scillas, of which several species are hardy. The earliest to bloom is

S. maritima, the flower-spike often appearing above the ground towards the end of February or opening days of March. In the type the flowers are of a deep blue, from four to eight being carried on a spike some 5 inches in height. The form known as *S. praecox* is rather earlier to bloom than the type, and has slightly larger flowers. There are many

Lilium longiflorum in a South Devon garden.

varieties in England is due, I fancy, to the general rule of treating all the Lilies classed as "Japanese" alike. I have not had a wide experience, but I have proved that *Lilium auratum*, *L. speciosum*, and *L. longiflorum* need totally different treatment. The general advice, "Plant in partial shade amongst low-growing shrubs," is quite right for *L. auratum*, a woodland Lily, but it is only partly right for *L. speciosum*, as this Lily loves sunlight, and I have found it quite wrong for *L. longiflorum*, which seems to need much sun, full exposure, and unlimited quantities of water, if free from lime. Anyone can flower imported bulbs—that is, given sound bulbs and a peaty soil, but it is the growing of this most beautiful Lily that is the difficulty. I have a theory of my own that its native habitat is in open, fertile, moist plains along watercourses, or in alluvial soil, as in the delta of streams, the natural soil being the porous, fertile, volcanic rock, covered by organic soil carried there by rain or river—well-drained, yet always moist. Again, it is quite one of the earliest Lilies to flower, and one of the most interesting writers on Japan has said that there are "Forty wet days in June in the Land of the Chrysanthemum." *L. longiflorum* is the only Lily I water in dry weather. This summer it has luxuriated in the constant rain which has ruined the *L. speciosum* and *L. auratum*. In native pictures of this Lily, grown for commercial purposes, it is always in open fields, like the Tulip farms of Holland. I first tried growing it with a carpet of Funkias amongst low shrubs, in a sunny place. I had a grand show of flowers the first year, but the bulbs mostly "broke up" after flowering. Planting in partial shade was worse, for every bulb "broke up." From one patch of twelve flowering bulbs I had about 100 small bulbs, varying in size from a big Pea to a Hazel-nut. This tendency to break up after once flowering into many small bulbs is one of the troubles of cultivating this Lily, but I find it is particularly natural to all, or nearly all, of the Trumpet

Some of the groups had twelve flowering stems this season besides a good many young growths; in one case twenty-three in all. A narrow border divided the Japanese garden from a wide path, running from N.E. to S.W. Some giant *Ilex trees*, 12 feet away, quite shielded them

Scilla hispanica in the wild garden. From a photograph by Miss Gaisford, Dunboyne.

from east wind, also from all morning sun, a very necessary precaution with a Lily that starts into growth so early in the year as this one. The full strength of the winter sun is allowed to cover or shade

varieties of *S. bifolia*—namely, the white *S. bifolia alba*, the flesh-coloured *S. b. carnea*, and *Queen of the Valley*. Lately two improved forms named Pink Beauty and White Queen have been introduced. They are not yet pro-

curable, except by special favour. *S. bifolia* should be left undisturbed, when it seeds freely like its relative the *Chionodoxa*, and in a few years is surrounded with hosts of self-sown seedlings. *S. taurica* is another form of *S. bifolia*, with more numerous and larger flowers, as many as twenty being sometimes borne on a single scape. This *Scilla* is not exacting as to position, succeeding as well in the shade as in sunshine, as is the case with other species of the genus.

THE SIBERIAN SQUILL (*S. sibirica*) is another very beautiful early-flowering species, the colour of its flowers, a bright porcelain-blue, seen in some of the best of the Delphiniums, being more telling than that of any other species. It prefers a somewhat light, porous soil. Of late years a white variety, *S. sibirica alba*, has been raised, but although this is an acquisition, it is, as is the case with many white-flowered varieties of well-known types, inferior in effect to its delightfully-coloured parent.

THE STAR HYACINTH (*S. amena*) is a strong-growing species, producing its blue flowers in April. Its foliage is nearly a foot in length, and is of a pale yellow-green colour. It is well adapted for edging shrubberies.

S. NUTANS, popularly known in England by the erroneous title of Bluebell, is, though a common wild flower, the most graceful of the whole race. Who is there that has not been fascinated at the charming picture presented by a wood carpeted as with the azure of the sky by closely-set myriads of its arching blue scapes? No more beautiful sight can be imagined than that afforded by the Wood Hyacinths in full flower in early June, beneath the trees around Queen's Cottage, Kew Gardens, where for hundreds of yards they form a sheet of shimmering blue—a sight at the door of every Londoner. Much as has been said in praise of other *Scillas* for naturalising, it is certain that none are so valuable for this purpose as our English Wood Hyacinth, for none can approach it in grace of poise. White and rose-coloured forms of *Scilla nutans* are often met with, but though pretty and interesting as curiosities, the rightful tint of the "Bluebell" is to be preferred.

S. HISPANICA, also known as *S. campanulata* (see illustration), is a profuse flowerer, and is easily naturalised in the wild garden. It is, as may be seen from the picture, very ornamental as an edging for a narrow path backed by evergreens, and is charming when associated with London Pride (*Saxifraga umbrosa*), whose delicate flesh-white flower-sprays contrast so well with the sturdy blue scapes of the *Scillas*. *S. hispanica* bears upright flower-scapes, which, though handsome in the mass, lack the grace of the bending scapes of *S. nutans*. There is a white variety of *S. hispanica* which is in much request for market work.

S. ITALICA bears pale blue flowers, with darker coloured stems, on spikes 10 inches in height, one spike sometimes holding as many as twenty or thirty flowers, which are sweetly scented. It thrives best in a light sandy loam in a sheltered position.

S. PERUVIANA is not, as might be imagined, a native of Peru, but of the Mediterranean region. Its foliage is broad and Yucca-like in shape, and it bears a dense pyramidal head of purple-blue flowers, very closely set, the flower-heads being often over 11 inches in diameter at the base. It is more curious than beautiful. It grows in quantity on the steep rocky slopes at Gibraltar, and should, in this country, be planted in shaly soil in a sunny but sheltered position. S. W. F.

THE MIXED BORDER BEAUTIFUL.

TO THE EDITOR OF "GARDENING ILLUSTRATED."

SIR,—As a great admirer of hardy flowers, I have read with interest several excellent articles on the arrangement of herbaceous mixed borders which have appeared in recent numbers of GARDENING ILLUSTRATED. As there are proverbially "two sides to every question," perhaps you will allow me to air another theory on the "Mixed Border Beautiful." I have every sympathy with those who are trying, by advocating "schemes of colour," to prevent the painful mixing of such colours as scarlet and magenta, or strong and crude blues and reds; but it seems to me that there is some danger of the

"colour scheme" theory being done to death. One point that is thoroughly insisted upon is that "plants of the same colouring are intergrouped, so that the red group, whether early or late, is always a red group, and so on throughout." Now, personally, I cannot imagine anything more depressing and monotonous than the thought, when looking at some spot in my garden in early spring, that the red group would always be red—red in the fresh days of spring, red through the hot summer months, red still in the autumn, until a kindly frost came and by force blotted out its unchanging redness. By following this plan of intergrouping colours, the broad general effect of the border would always be the same, spring, summer, and autumn. What could be more at variance with the model "colour scheme" of Nature? I take as an instance the stretch of wild moor and forest over which it is my privilege to look at all seasons of the year. There, in spring, is a "colour scheme" of gold—one sheet of yellow Gorse. This changes to the strong summer crimson of the Bell-Heather, mixed with the grey-green of the Gorse bushes; then the softer pink of the Ling, which in turn gives place to the russet and purple brown of the winter. And the wood, for its part, passes through the pink flush of the leaf buds, the vivid young green, the duller, deeper tones of summer, and the glory of autumn tints, to the bare, leafless beauty of winter. How much of the wonderful charm would be left if the forest were always green, the slope always golden, the moor always purple and pink?

At the risk of taking up too much space, I should like to give briefly my idea for following this lesson of Nature. The first broad effect in the border would be a yellow one—Daffodils of all sorts and shades, planted in groups of about a dozen, some 10 feet apart, all down the border. These would be followed by *Doronicum* and *Polyanthus* of suitable shades. Very soon a note of blue and white would be introduced by Forget-me-nots, White Arabis, *Scilla campanulata*, and *Narcissus poeticus*. As the yellow died away, pink would be mixed with the blue and white by May-flowering Tulips, London Pride, herbaceous Peonies, etc. These would go on until the dominant note is given by the Roses. This is perhaps the easiest time, for if scarlet, strong yellow, and magenta are rigidly excluded, it is difficult to go wrong. White is always permissible, and Pinks, followed by Madonna Lilies, Marguerites, and a host of others, will give point to the haze of pink and blue. Roses, Delphiniums, Columbines, Sweet Williams, Shirley Poppies, and nearly all the old-fashioned annuals will harmonise together, and be followed by pink and crimson Hollyhocks and herbaceous Phloxes. Pale yellow and sulphur shades will also mix well. Gradually the sky-blue and rose-pink summer time will change into the mauve, violet, and purple of the season of Asters. No matter if the period overlaps a little; the new tints will not quarrel with their predecessors. Then, by the time the pink is well out of the way, the perennial Sunflowers, and the orange, flame, and scarlet of the Cactus Dahlias and Tritomas may enliven the autumn days. Only, if these are desired, it may be safer to leave out the later flowering pinks, such as Hollyhocks and Phloxes, in case any should linger on and jar with the succeeding scarlets. Finally, tawny-red and bronze, sulphur, yellow, and white Chrysanthemums will carry the brightness of the border well on into winter. In this way an ever-changing general effect is produced in harmony with the moods of the different seasons. Of the difficulties of carrying out such an ideal successfully I am well aware from my own experience; but I believe they may, with care and thought, be overcome. L. D. L.

PLANTING TUFTED PANSIES.

Will you please tell me the best time of year to plant out Tufted Pansies, and also the names of some of the best blue varieties? Would Pansies bloom from seed the same year as sown?—J. R. PHILLIPS.

[Tufted Pansies may be planted out at almost any season, so long as the weather is fairly dry and frosts are not severe. Plant in the spring for early summer and autumn displays, and in the case of plants intended to flower in the hardy border as early as possible in the spring.

time, we prefer to put out the plants during the early days of October. A November and even a December planting, when the weather has been free from severe frosts, has given us splendid results, and for this reason, assuming that you can obtain plants of what you want at once, you may plant with every confidence of being successful. In the meantime get the soil in order. First deeply dig the beds and borders which it is intended to plant, and at the same time incorporate some good rotting manure. Leave the surface-soil fairly rough until you are ready to plant. If you desire a free and early display plant rather closer together than usual—6 inches apart should answer very well. Should large blooms be preferred, 9 inches or 1 foot should separate each plant. Plant firmly. Blue Tufted Pansies are not by any means plentiful, many of the varieties being tinted purple or violet, and sometimes lavender. The following, however, may suit you:—

ARCHIE GRANT.—This old variety is sometimes met with under the name of Admirable, and a slightly improved form of this popular kind is now being distributed under the name of William Haig. The colour is nearer an indigo-blue than any other shade of blue. The flowers are large and possess plenty of substance, and have what some consider a blemish—a black blotch in the centre. Habit rather coarse and not by any means creeping.

MAX KOLB.—A free-flowering plant with a fair habit and good constitution. The blossoms are borne on long and stout footstalks, well above the foliage, and when at its best the plants are much admired. Colour a deep blue.

Mrs. C. TURNER.—This variety is not very generally catalogued now, but if plants can be procured, a free display of deep blue blossoms can be had another season. It is a good self-coloured flower.

TRUE BLUE.—A very old sort, which in years past was highly regarded. Its colour, a rich blue, is effective, but the objection to the flowers is the heavy rays or pencillings which run into the eye of the bloom.

BLUE GOWN.—If this charming sort can be obtained, nothing better in the way of bright blue can well be planted. The circular flowers are rayless, and are faintly tinted mauve, and when the plants are massed the effect is very pretty. It is very free-flowering and of fine habit.

ADMIRAL OF THE BLUES.—This is a rayless variety, and the colour is a deeper shade of blue than most others. The neat yellow eye heightens the beauty of the self-coloured flowers. Its habit is not all that the grower would desire.

M. P. ROBERTSON.—A novelty sent out last spring, is not so good a self as the last-named, and the colour may be described as purplish-blue, paling towards the centre of the flower. As a free-flowering rayless kind it is good.

AUGUSTINE.—An 1897 seedling, very similar to Blue Gown, but with a better bloom, and also more robust constitution.

BLUE DIAMOND.—Something like True Blue in colour, but the flowers are larger and more circular.

BRITANNIA.—This is another seedling from Blue Gown, having flowers of good substance, and a wonderfully compact habit of growth. The colour of the flowers is darker than that of the parent.

JOHN SMITH.—Another pretty blue flower, tinted mauve, and a seedling from Blue Gown. Habit equal to that of the parent plant, and constitution more robust. Neat rayless eye.

PICMY.—A pretty miniature-flowered kind, and specially adapted for edgings to large borders. The plant flowers freely, and the colour of the blossoms is a deep heliotrope-blue, with a neat yellow eye.

KING OF THE BLUES.—This may be regarded as the best of all the blue-coloured kinds. Unfortunately, it is but little known, and the stock is in the hands of a few persons. The late Dr. Stuart was the raiser of this. The colour is a true blue, with a neat yellow eye, and the blossoms are rayless. The plant comes into flower rather later than most other sorts, but keeps up a display well into the autumn.

Pansies raised in the early spring and subsequently, say in April or May, planted outdoors should bloom freely in July or even earlier. (S. E. CHURCH, *Hypocistis*, N.)

THE MORE VIGOROUS WATER LILIES.

The *Marliacea* forms mark the introduction of hybrid Water Lilies and include the very best kinds. Although other varieties have been raised, these hybrids hold their own for general utility, being vigorous and strong in growth, flowers large and very effective when the plants are massed or planted as single specimens.

N. MARLIACEA first flowered at Kew in July, 1887, the bloom being of a rich canary-yellow. The leaves are marbled with reddish-brown on the surface, and blotched with purple on the lower side. In

N. MARLIACEA ALBIDA the flowers are very large, milk-white, the outside petals flaked with pink at the base, stamens sulphur-yellow.

in general appearance and size, but the flowers are of a brighter pink. The inside of the sepals is tinted with pink, stamens sulphur-yellow.

N. M. RUBRA PUNCTATA.—The flowers of this are deep rose-purple and delicately marbled, the sepals dark olive green behind and pale rosy-lilac in front. In

N. M. SANGUINEA the flowers are deep carmine with conspicuous orange-red stamens.

NOTES AND REPLIES.

Renovating cottage garden (*Notice*).—Whatever may be the condition of the soil in your new garden, it is best to assume that it is poor and not deeply worked, as that is the average state of gardens when fresh taken over, as a rule. If you can do so, have all the

soil, and the remark as to manuring, etc., is the outcome of this. In respect to plants, there are many things you may add. Where Michaelmas Daisies fail to bloom there is not much hope of other things in similar circumstances—that is to say, it would be useless on our part recommending a good assortment of plants unless the border is in condition to grow them. The plants mentioned below will be best planted in the early part of March ensuing. In the meantime we suggest you thoroughly trench the soil, giving a heavy dressing of manure as the work proceeds. If you treat the border thus you will find there is no need to discard the Michaelmas Daisies. It may be, however, the kinds are not the best, and the soil being exhausted would soon account for their poor flowering. For the time

stated you will find the following suitable: *Gaillardia grandiflora*, *Aquilegia chrysantha*, *Helenium Bolanderi*, *H. Hoopesii*, *Stenactis speciosa*, *Senecio Doronicum*, *Hemerocallis* in variety, *Coreopsis lanceolata*, *C. grandiflora*, *Centaurea montana* vars., *Delphinium Belladonna* and six other *Delphiniums* in variety, single and double *Pyrethrums*. Other good plants should include *Alstromeria aurea*, *Rudbeckia Newmani*, *Aster Amellus*, *A. Novi-Belgii deusis*, *A. lavigatus*, *A. cordifolius elegans*, *Campanula Van Houttei*, *C. grandis*, *C. g. alba*, *Lathyrus latifolius albus*, *Kniphofia aloides*, *Chrysanthemum maximum*, and German *Irises*. To these may be added *Carnations* in half-a-dozen good kinds, a few clusters of *Sweet Peas*, and a similar supply of *Gladiolus*. Such *Lilies* as *tigrinum*, *t. splendens*, *Martagon*, *umbellatum*, *spaciosum*, etc., will afford much variety and beauty. Tubers of *Anemone coronaria* may also be planted at the same time. There is no limit to the material that could be employed at such a time.

Wallflowers.—These seem as popular as ever. At this time of year, when beds, borders, and window-boxes are being cleared of their summer occupants, it is the Wallflower that quite naturally suggests itself as one of the first things to start upon. Even a small garden needs a good many to fill all the bare spaces. Now that there are so many shades of colour one may have a pretty display of Wallflowers alone. Amongst all the new comers the old, well-tried *Blood Red* and clear yellow *Golden King* hold their own. The great point to aim at in the cultivation of Wallflowers is to have the plants dwarf and bushy, with many side branches, close to the soil, and to get this the seed should be sown thinly in April or May on poor, light soil, in quite an open spot, where they are not drawn up by any overhanging trees. As soon as they are large enough to handle they should be dibbled into rows 1 foot apart each way, and the central shoot pinched out, to cause side shoots to develop more freely. Beyond keeping clean, they will require no further attention until the time comes to put them into their flowering quarters, when, if they have done well, they will be perfectly round specimens, with buds almost ready to burst. They should be very carefully lifted with a fork, so as to get the roots intact, for although they are such strong-rooting plants that they generally survive the rough order of digging up and sticking in again, they will repay a little more care.—J. G.

Nymphaea Marliacea carnea in Mr. Gumbleton's garden at Belgrove, Queenstown, Co. Cork.

This is one of the most vigorous Water Lilies we have.

N. M. CARNEA.—In this, a flower of which is here shown, the blooms are very large, the colour, as implied by the name, flesh-pink, stamens sulphur-yellow.

N. M. CHROMATELLA is one of the finest hybrids we have, the flowers soft yellow in colour, with a deeper centre, stamens sulphur-yellow.

N. M. FLAMMEA varies in colour, which consists of innumerable red dots on a white ground, the outer petals appearing pink and deepening to a wine-red in the centre. The stamens are bright red, leaves marked with chestnut-brown on the surface.

N. M. LIGNEA.—In this the flowers are of a rosy-crimson colour, stamens bright orange. This is a splendid variety for producing an effect in the distance, the colour being so intense.

N. M. ROSEA.—This resembles *N. M. carnea*

kitchen garden ground trenched from 20 inches to 24 inches deep, breaking up the bottom-spit of soil, and leaving it there, but adding some manure before you put the next top-spit of soil on to it. Then, if you could take advantage of frost later, would wheel on a further dressing of manure, and so soon as the ground was thawed would well fork that in, the garden would be in fine condition for cropping in the spring. If the soil be stiff, exposure to frost does it good. The flower borders should have all plants taken out, be manured and deeply dug, then be replanted. Probably many of the herbaceous plants, if large, would require dividing before being replanted. Privets should be lifted and replanted now; then at the end of March cut them hard back, and they will break afresh low down.

Border plants for June and July, etc. (*Perennial Border*).—From your letter we conclude the border needs deep digging and manuring. We well know the district and

King hold their own. The great point to aim at in the cultivation of Wallflowers is to have the plants dwarf and bushy, with many side branches, close to the soil, and to get this the seed should be sown thinly in April or May on poor, light soil, in quite an open spot, where they are not drawn up by any overhanging trees. As soon as they are large enough to handle they should be dibbled into rows 1 foot apart each way, and the central shoot pinched out, to cause side shoots to develop more freely. Beyond keeping clean, they will require no further attention until the time comes to put them into their flowering quarters, when, if they have done well, they will be perfectly round specimens, with buds almost ready to burst. They should be very carefully lifted with a fork, so as to get the roots intact, for although they are such strong-rooting plants that they generally survive the rough order of digging up and sticking in again, they will repay a little more care.—J. G.

INDOOR PLANTS.

POTTED BULBS.

It is not too easy to make those who have had little experience in bulb culture, and wish to grow some successfully in pots, to understand the rationale of putting the pots when filled with bulbs in a dark place, or covering up with ashes or Cocoa-nut-fibre refuse outdoors for a few weeks before exposing the pots to light and air. If those who do not understand the reason for doing this, but lift from the borders a few bulbs of any description just as the points of the leaves are coming through the ground, they would then observe that these bulbs have all made strong roots, showing that root action has some time preceded leaf or crown growth. Outdoor bulbs are invariably planted deeper than in pots, also the atmosphere is, as a rule, cooler than is the soil. Bulbs in pots stood indoors usually find things reversed, and if the top or leaf growth precede root action, then the flowers and leaves produced will be relatively weak. When bulbs are in pots they should be at once stood outdoors on a hard, dry floor of ashes, gravel, asphalt, or slates, or otherwise worms will get into the pots from the ground. Sifted coal-ashes is capital and cheap material to cover them up with, filling in between the pots, and over all some 3 inches thick. Where a number of pots is so treated, and the earlier for some the better, then after six weeks of such treatment a few can be got under glass each week or fortnight, as outdoor growth, especially in cold weather, will be very slow. When taken under glass the pots should be first put into a very moderate warmth, then into greater heat after a few days' exposure. Market growers who grow thousands of bulbs in boxes for forcing under glass treat all in this way. Even Hyacinths in glasses should be placed in a dark cupboard in a cool room for a few weeks to cause roots to be formed ere exposing them to the light.

LEAN-TO GREENHOUSE.

(REPLY TO "MARY.")

You could arrange it in this way. Carry a bed 3 feet 6 inches wide along the entire front part, devote a similar width to the path, which will admit of a 3 feet door, and you have 7 feet or nearly this for the main stage at back. Dividing this into three equal-sized step stages will render it more convenient. For the front the best stage is composed of 1-inch barrel iron pipe and wood bearers 4 inches by 2½ inches or thereabouts let into the front wall, say 3 inches, to form a stay, the iron barrel sunk 6 inches in ground, set on brick, and fixed on concrete, and countersunk in wood, say 1½ inches deep, the hole set back 6 inches from face. This iron upright and wooden bearer are best covered with corrugated iron sheets, nailed on, and constituting a practically indestructible stage. It should be 3 feet high when finished. By using iron sheets of 22 gauge, the bearers could be placed 5 feet apart. Sifted coal-ashes on these sheets make one of the finest stages for plant growing we know of. The back stage may be of the same iron uprights and wood bearers, but the stage will of necessity have to be made of wood laths. Sliding lights for front would do quite well if you can make sure of perfectly seasoned wood in the manufacture, otherwise the ordinary deals will so swell up with moisture as to give much trouble in opening, etc. In other ways they are as useful as any. If you wish for Ferns, the better plan would be to construct a glass partition at the end opposite from door, and by darkening the glass outside a more humid condition could be maintained. A partition, say 5 feet wide, having a 3 feet stage and a 2 feet pathway would grow many good Ferns quite well. The best position for a Peach-tree would then be in the centre at the front, bringing the stem and head up through an aperture in front stage, and accommodating the roots in a prepared bed of soil below the stage. By training the branches near the roof you may grow as fine fruit as is possible. Indeed, one plant we can call to mind in just such a position and in a house not much larger than yours as a whole, has for years produced an average of some 400 dozen fine fruits. The house is heated, however, and the gardener highly experienced. Still, had

is ample room for success in your case by getting a good tree and planting it well. A good and always dry pathway can be made with a bed of concrete, say 6 inches in thickness, to be covered with sharp sand, granite chips, and cement gauged up to two and one.

NOTES AND REPLIES.

Acacias.—The grower of Acacias who has had his plants standing out-of-doors should now see that they are taken inside without further delay, as one night's frost will ruin the chances of bloom. The house where Primulas and Pelargoniums, etc., are wintered will suffice for Acacias, and early in the year one may get any amount of yellow bloom. *A. pulchella* and *A. Drummondii* are two of the most useful sorts.—W. F. D.

Passiflora bleeding.—I have a *Passiflora carulea* planted in the back border of conservatory, which, on account of growing so fast, had completely covered roof and side glass, therefore was advised last week to cut it back to the hard wood, which I did to within 4 feet from the ground. Consequence is, ever since, it has bled profusely. I should be much obliged for advice as to its treatment, as I am afraid it will die. If not, is it likely to break out again in the spring?—R. W. M.

[It was a mistake to cut your plant down as you have done. You could have thinned it out in such a way that light could reach the plants underneath. If you were compelled to cut it down, then you should have left it till the growth was beginning to move in the spring. In the meantime, keep it fairly dry at the roots until you find that the bleeding has ceased.]

Begonia fuchsoides.—While some classes of Begonias have at the present day attained a high degree of popularity, others are allowed to a great extent to pass unnoticed, and among these last must be mentioned *B. fuchsoides*, which is a really handsome species, though the individual blossoms are but small. It is one of the fibrous-rooted section, and in a warm greenhouse will, under favourable conditions, reach a height of 6 feet. This *Begonia* is, for such a structure, one of the best pillar plants that we possess. The leaves are ovate, about 1½ inches long, of a deep shining green when mature, though in a young state they are tinged with red. The bright scarlet flowers are borne in large drooping panicles, and where favourably situated will keep up more or less of a succession for a considerable period.

Lantanas are useful either for greenhouse or conservatory decoration, their brightly-coloured blossoms being attractive, and quite distinct from those of their associates. Somehow or other, however, *Lantanas* have, in most places, nearly dropped out of cultivation; yet, apart from their value as flowering plants at this time of the year, they form pretty little bushes when planted out-of-doors during the summer, where they continue to flower for months together. Their culture is not different from that usually given to *Fuchsias*. The one enemy to guard against is red-spider, which is likely to attack them during hot, dry weather in summer. If cuttings are struck in spring, and stopped once or twice during the season, they form bushy little plants in 5-inch and 6-inch pots, full of bloom buds, by the autumn. Seedlings raised early in the year and grown on freely will also bloom well in the late summer months.

Nasturtiums in pots.—Until last year I had never seen *Nasturtiums* grown in pots, but wishing a change of plant and of flower for house decoration I resolved to try the *Nasturtium*. The seeds were sown in 5-inch pots in June, and stood outdoors until the end of September, or rather until frost deemed it advisable to remove them to a place of safety. This date for sowing proved too early for the purpose I had in view, though it may not be so in every instance. They came into bloom under the coolest conditions I could afford them in October. This year, instead of June, the latter part of July was chosen to put in the seeds—four in each pot. Outdoors the plants advanced more slowly, due to the cooler weather, and at the end of September they are beginning to open a few flowers, a crimson and a yellow kind being grown. I maintain that, though they may be common, they are useful in winter when all is dull and flowerless out-of-doors and their natural season is gone. A

supply of flowers for cutting will be maintained until Christmas, and they have a pretty effect arranged in small vases, accompanied by their own foliage. It would presumably be too late now to sow seeds even for an early spring display—there is not sufficient sunshine to give strength to the plant in its early stages—but this note may remind readers of the possibilities of a pleasing display at a trifling cost.—W. S.

Fumigating plant houses and pits.

—At this season of the year there is frequently an increase of aphides and thrips, but more particularly the former. This will occur in nearly all houses, be they warm, temperate, or cold. This should be nipped in the bud, for it never pays to defer fumigation when even only a few insects have to be destroyed. When a case becomes a bad one, a strong dose is often given and a repetition within twenty-four hours; the repulsion may be all very well, but the strong dose is no more needed than in the case of a few insects only. It takes no more actual strength to kill 1,000 than it does to kill 100. Frequent fumigations so as to make them as distasteful as possible for the insects are by far the better plan. Everything in the house or pit should be as dry as it is practicable to make them. By this it is not, of course, inferred that dryness at the roots is intended; it is rather that of the foliage and among the plants. Moisture acts as a deterrent to the free circulation of the smoke, and when it exists upon the plants the result will not be so effectual. It is not so much that the smoke will act injuriously where there is moisture as that it should reach all parts of the plants.

CHRYSANTHEMUMS.

AMATEURS' CHRYSANTHEMUMS.

No doubt many readers of this paper are in the same position as I am, and that is, I am a considerable grower of *Chrysanthemums*, not for exhibition, and I am too far away from nurseries and other places where they are grown in quantity to avail myself of a visit to select varieties for my purpose. A visit to a show enables me to see a few huge blooms, and that is all. Some of your contributors would do a real service if they would give a list of fifty to a hundred Japanese varieties, which would give blooms, under an ordinary amateur's mode of growth, of a fair size, three to four to a plant, and not difficult to grow this last being a *sine qua non*. As an example, I may mention *Soleil d'Octobre*, to my mind the *beau idéal* of what an amateur's plant should be, in growth, habit, and bloom. On the other hand I should exclude *Emily Silsbury*, which has a bad habit of growth, and is too weak in the neck to be satisfactory, and *Mme. Carnot* and its varieties, all of which are too uncertain—in fact, I find really good whites scarce. *Western King* and *Niveum* are, of course, good, but they are late, and cuttings are scarcely, if at all, produced. Mere decorative varieties are not what my query aims at obtaining a good list of.

NORTH COTSWOLD.

NOTES AND REPLIES.

Chrysanthemums damping off.—Can you suggest a reason for the failure of my *Chrysanthemums*? I p to the time of the opening of the flowers the wood and foliage never looked better, as is the case still. As soon as the flowers began to open the outside petals dropped off, and of eighty odd plants, in hardly one instance did the flowers live to expand. Partial damping off of outside petals has happened to me before, but never such an early complete failure, or such a rotting away of the centres of the blooms.—AMATEUR.

[Complaints of *Chrysanthemum* flowers damping are common this season, brought on, no doubt, by the growth being badly ripened owing to the unfavourable and sunless season we have had. Faulty ventilation will also often cause damping. Enough ventilation can be afforded by opening the top lights only. Sufficient fire-heat should be employed to keep the glass dry inside and render the atmosphere pleasant but not too hot and dry. Overfeeding, again, may be the cause, as the roots are killed and unable to do their work. It is always advisable to do the watering early in the morning, so that all moisture may be dried up before the

evening. If any floret exhibits signs of decay at once pull the same out, as damping is catching, and the whole flower will speedily be ruined.]

Chrysanthemum, incurved, Mrs. George Rundle and its sports.—At the recent Sheffield Chrysanthemum Society's show incurved Chrysanthemum blooms were well represented, and to growers in the south would be a great surprise. The most interesting class, however, is that devoted to six blooms of Mrs. George Rundle and its sports. In the competition referred to, there have to be shown two blooms each of Mrs. George Rundle, white; Mr. George Glenny, pale yellow; and Mrs. Dixon, rich yellow; and the board on which they are displayed has to be covered with Moss. The blooms have to be cut with stems not less than 7 inches or more than 9 inches in length, and also have to be shown with their own foliage. Each season the competition is good. There were nine exhibits on the 14th instant, and the majority of the blooms were excellent. They were a

properly representing this and other small flowered types of the Chrysanthemum that makes our exhibitions so monotonous and uninteresting. The large flowers are encouraged to such an extent that little or no notice is taken of the quaint Anemone-flowered Pompons. There is no more opportune occasion than the present for pressing the claims of these flowers. If the Chrysanthemum shows are to remain popular with the general public, novelty in this way must be provided. These flowers, if properly represented at shows, should be an object lesson to growers who desire to make the most of the different types of these flowers for decoration.—C. A. H.

ROOM AND WINDOW.

A GOOD ROOM PLANT (ANTHERICUM VARIEGATUM.)

This handsome half-hardy plant (here figured) is well worth attention for furnishing small vases, pots, etc., for conservatory and room

rooms all through the year. I know of no way of doing this better than growing many kinds of plants in small pots, and many of the most common are highly ornamental. At this season few things are more attractive than small plants of Zonal Geraniums, in 3-inch and 4-inch pots. I have some now of West Brighton Gem, etc. These can be turned out of the pots and dropped into the vase as they are. I put them into some small vases used for cut flowers in summer, and if changed occasionally they last a long time. Coronillas, small Genistas, Cyclamens, Violets taken up in clumps, Solanums, and Ophiopogons I have found useful. Then we have Primula obconica and P. sineasis. Nothing is more useful and ornamental, and when sown late and grown on without a check they throw up a strong spike in a 3-inch pot. P. stellata throws up the spikes high out of the leafage. Many other flowering plants may be named, but I must mention a few fine foliaged plants. Abutilon Thomsoni, when rooted late and grown in an open position is beautiful. Coleuses are also serviceable. Panicum variegatum, when several cuttings are rooted round the pot and pinched, make fine subjects. Lately I took a good plant in a 4-inch pot, placed it in a vase in the drawing-room on a raised position, where it hung all round the vase with good effect. Grevillea robusta, Aralias, Eucalyptuses, Coprosma Banori, and many of the scented Pelargoniums are especially suited for this work. Scarlet Salvias, if good cuttings are put in three round a 4-inch or 5-inch pot early in July, come in well to give colour. Nor must I omit the numerous Ferns that are so useful for this work, and many well nigh hardy plants may be used in this way. In proof of this I may name plants of the smaller growing Funkias, especially the variegated forms, Lily of the Valley, bulbs of all kinds, although I prefer to grow these in boxes, etc., taking them out when in bloom and putting Moss in vases to keep them in position. I must not omit to name Cinerarias, which are beautiful. The most important part in the culture of plants in this way is that they should not be starved in any way. Everyone can use some of the fertilisers now advertised, and by changing the food of a plant once or twice weakly it is astonishing what fine plants can be grown in small pots.

J. CROOK.

FERNS FOR ROOMS.

SOME of these are very useful for vases to stand on brackets or drawing and sitting-room tables, if we consider their graceful effect and the length of time (with a little care) that they will remain in good condition. A judicious selection of Ferns is, however, necessary to ensure success, as they do not all do equally well under such conditions, nor are they all adapted by their habit of growth for this kind of work. Given the right kinds, the plants must receive careful preparation, for if they are taken straight from a moist, warm glass-house, their period of service will be a very brief one. If, on the other hand, grown to the required size in a genial temperatura, and then gradually inured to full exposure in a cool greenhouse, the fronds will get hardened and they will last many weeks, or even months, with care in watering and occasional syringing with clean, warm, soft water overhead to wash off the dust that is sure to settle on them. In transferring the plants to the vases shake away the soil, so as to get all the roots entire, then put a layer of crocks, broken up fine, at the bottom, over a hole drilled previously in the vase, then work the roots carefully into the vase with very finely-sifted soil, pressing down firmly and finishing off with a layer of fresh, green Moss. Give a good watering after setting the vase in its saucer. By this means really effective plants may be got to live for a long time, and even make good growth in dwelling-rooms. The small vases, that are made in various coloured earthenware, can hardly be expected to do more than sustain the plant of the size it is when transferred from the pot in which it was growing, but if larger ones, in proportion to the size of the plants required, are used, there is no reason why greenhouses should not only live, but make fine specimens in dwelling-rooms.

A good room plant (Anthericum variegatum).

splendid testimony to the value of these three beautiful sorts for decoration, and as their culture is distinctly easy, readers of GARDENING ILLUSTRATED should include them in their future selections.—W. V. T.

Single Chrysanthemum Miss Rose.—This comes of a much deeper colour, I find, when given outdoor culture than when grown in pots, it then being quite a rose pink, whereas under glass it is but pale pink. It is of hushy habit, and does not exceed 18 inches in height, the plants being quite covered with medium-sized blossom. For the front row of Chrysanthemum borders Miss Rose and King of Siam are both useful on account of their dwarf habit and freedom of flowering.—A. W.

The Anemone flowered Pompons.—I fail to see why the beautiful little Anemone-flowered Pompons are, so to speak, ousted from the exhibitions of Chrysanthemum societies in all parts of the country. Only one class is provided in the schedule of the N.C.S. at their November show, and this of such a character that little can be done to display their charming qualities. It is the lack of

decoration. It was introduced from the Cape in 1875. In variegation and habit of growth it resembles the well-known Pandanus Veitchi. It is, however, far more easily grown, and its foliage never fails, if given fair treatment, to assume a bright grass-green colour, beautifully striped and margined with creamy-white. It does well in good loamy soil, to which have been added some sand and leaf-mould. Care should be taken that the pots are well drained, as abundance of water is necessary when the plant is growing freely.

SMALL POT PLANTS FOR HOUSE FURNISHING.

EVERYONE should endeavour to keep his rooms gay with flowers, especially through the winter months, when things are not so attractive outside. I am convinced that nothing makes rooms look more cheerful than plants and cut flowers. Some may say it is an expensive matter, but it is astonishing what may be done at a little cost. It is not the most expensive material that is the most enduring or ornamental, and there are few who make a garden of any size but may have gay

Asplenium bulbiferum is a good Fern for hanging-baskets or vases set on brackets, as its long, arching fronds, with tiny little embryo plants set thickly along them, have a very striking effect. Perhaps the best of all for small vases are the numerous varieties of *Pteris* or Ribbon Fern, such as *P. longifolia*, *P. serrulata*, and all the crested varieties allied to it. Then there is the variegated *Pteris cretica*. *P. tremula* in its young state is very good, and when too large for a room, if shifted on it makes a fine specimen. Some of the hardiest *Adiantums*, such as *A. formosum* and *A. capillus-Veneris*, answer well, and *Blechnum braziliense* and the smallest *Lomaria gibba* look very pretty, as their Tree-Fern-like habit, although in miniature, makes a nice contrast to the more gracefully drooping kinds.

ROSES.

ROSES IN COLD GREENHOUSES.

(REPLY TO "STAFFORD.")

You are very wise to locate a cold greenhouse to Rose growing in a district that is unsuited to successful Rose culture outdoors. *Gloire de Dijon*, one of the best old Roses for the purpose, should not receive much pruning. The long growths made this summer should be laid in almost their entire length, if there is space; otherwise, it would be better to discard some of the older growths in order to provide space for the new. The short lateral growths proceeding from the main stem may be cut back to four or five eyes, or even less. We should not recommend you to commence pruning too early. February is a very good time for Roses in a cold house. Plants purchased in pots, if of the dwarf growing kinds, should be pruned back to about half their length, the weaker ones being pruned the most severely. Climbing kinds may have their long growths twined around three sticks. They will then blossom freely from almost every eye; if not during the spring and early summer, they will do so in autumn.

The H.P.'s you mention need not be repotted each year. If you see that the drainage is not choked and top dress them at once, the plants should be all right until next summer. We usually like to repot such Roses in July. They then have several weeks in which to make new roots and become established. In pruning the Hybrid Perpetuals retain about 4 inches or 5 inches on each shoot produced this season, unless it is soft and pithy.

ROSES IN NOVEMBER.

From the beginning of July right up till now, November 17th, my Roses have made a splendid show, the last to bloom being the Hybrid Teas and Teas, which never seem to rest if the weather is at all mild, but keep pushing up their buds as fast as the old blooms are removed, the most notable ones being *K. A. Victoria*, *C. Testout*, *Mme. A. Chateau*, *Maman Cochet* and its white form, and *Enchantress*. If the beginning of the Rose season was late it has now amply made up for the deficiency.

Rose *Mme. Pierre Cochet* has given me much enjoyment grown on a south wall, not nailed to the wall, but trained on a wide-meshed lattice placed a few inches away. This admits air to both sides, and is infinitely better than having the wood and leaves touching the bricks. The Rose mentioned is a splendid orange-yellow, grand for button-holes, and when in the bud, or half open, does not lose its colour or come white, as *W. A. Richardson* does. It is superior to the latter Rose in every way—a little larger, well-formed pointed buds, a vigorous grower, shoots 10 feet to 12 feet in a season, almost free from mildew—in fact, a Rose that can be confidently recommended. As other instances of the lateness of the season may be mentioned the fact that two boxes of Rose-blossoms (not for competition), and very pretty they looked, were shown by Messrs. Harkness and Co. at the Hitchin Chrysanthemum Show on November 14th, and attracted considerable attention. No frosts of any severity have yet occurred, and the borders are still gay with many flowers, such as *Dahlias*, *Verbenas*, *Scabious*, *Calliopsis*, *Tobacco*, and, of course, outdoor Chrysanthemums,

which have done splendidly, although most varieties appear a month or more late: *Harriet Hume*, an early one, is in bloom now, also *Queen of the Earlies*. Sweet Peas, too, are also in bloom, and only a few days ago the last dish of Green Peas was picked from a row of Autocrat sown in May. Although everyone was grumbling at the cold spring and east winds we had in April, May, and part of June, the few foregoing remarks will prove we have been fully compensated on that score.

Stonewall, Herts.

H. F. M.

AUTUMN-FLOWERING PILLAR ROSES.

The pillar form seems the more natural style of growth for many of our vigorous-growing Roses. Perhaps the finest effect is produced by the early-flowering kinds, such as *Crimson Rambler*, *Félicité-Perpetue*, etc., but if we lose this effect somewhat in the autumns, there is the additional value of blossom at a season of the year when the summer Roses are flowerless. Now that Rose gardens mainly consist of the free-growing kinds, anything that lends additional charm to the rosary should be welcome. This, I believe, can be secured by the planting of some of the varieties enumerated below, either on pillars or grouped in beds to remove any flat appearance which all dwarf plants would produce. Many or all of them would also be splendid as standards if procurable, otherwise planters would do well to provide themselves with such kinds by budding some standard Briers in the reserve garden. What could be more beautiful than a fine pillar of *Gloire de Dijon*? I have one now in view as I write, and it has been more or less covered with bloom all the summer. Bending a few of its strong growths will cause a more abundant blossoming on the same lines that pegging down the shoots will do with bush plants. A worthy companion to this lovely Rose is *Kaiserin Friedrich*, which in autumn puts on that pretty pink flush that is so much admired. Then, too, there are *Mme. Bernard*, *Bouquet d'Or*, *Belle Lyonnaise*, and *Mme. Moreau* also of this race that vie with each other in beauty of blossom. The last is, in my opinion, a far more beautiful Rose for outdoor growth than the much-praised *Sunrise*. However beautiful *Sunrise* may be under glass, I have heard no one commend it for outside culture. Of course, its habit is quite different, but if we can obtain blossom as beautiful on a strong-growing standard or pillar Rose, such as *Mme. Moreau*, so much the better. *Mme. Alfred Carrière* and *Reine Marie Henriette* would make a fine pair, they both being extra vigorous and about equal in habit, the one a showy creamy-white, well set off by its Grass-green foliage, and the other, when allowed freedom, a magnificent pillar Rose with light crimson, egg-shaped flowers. This Rose is often condemned, but I think unjustifiably. It is true mildew often sadly mars the foliage, but this can be remedied by timely application of a curative, as advised in a recent issue by your able correspondent, J. Crook. Some other good bright-coloured pillar Roses for autumn are *Francois Crousse*, *Noella Nabonnand*, *Longworth Rambler*, *Sonn. de Mme. J. Metral*, *Waltham Climbers No. 1 and 3*, and of less vigour, although quite strong enough for pillars, *Ella Gordon*, *Ulrich Brunner*, *Gross* and *Teplitz*, and *Corallina*.

Pink Roses of all shades are always welcome as pillars. The old *Blush China* is not planted nearly so frequently as it might be for this purpose. How it would live up the base even of a pergola, where, perhaps, a summer bloomer has nothing to give at this season of the year. Why is not the beautiful *Mme. Marie Lavallo* more often planted? I consider it one of the loveliest of semi-double Roses, and *Pink Rover*, too, is one of the sweetest, with a charming bud, if, perhaps, rather uninteresting open blossoms. The rich colour and stately blossom of *Climbing Mrs. W. J. Grant* provide the grower with a splendid pillar of rich pink flowers, not so numerous as in summer, but yet very valuable. Golden-yellow is obtainable in *Billiard* and *Barre*, and, to my mind, it is one of our best novelties. *Gustavo Regis* is also good, and one must not omit *Wm. Allen Richardson*. White Roses, always useful, have a pleasing effect in our somewhat grey autumn, and especially interesting are they as evening

approaches. *Aimée Vibert* is still one of the best, and a very pretty kind, with yellow buds and white open flowers, is *Alister Stella Gray*. This Rose seems to possess a deal of the true *Noisette* character. Another little-known Rose that has scarcely ceased flowering all summer and autumn is *R. Pissardi*, evidently allied to *R. moschata*. Its semi-double flowers are very pretty, and they possess a strong Musk-like fragrance. It makes a very interesting low pillar Rose. Hybrid Musk Roses, such as *Rivers'* and *Eliza Werry*, are good autumnals, which are seen best as pillars. I had almost overlooked two beautiful kinds—*Bardou Job* and *Gloire des Rosomanes*. Both make fine pillars of moderate height. The *Rugosa* Roses, especially the newer kinds, such as *Conrad F Meyer*, the *Noisette Perpetuals*, as *Mme. Alfred do Rougemont*, and the *Bourbons*, such as *Mme. Pierre Oger*, are all worth attention, making pretty centre objects for beds or autumnals, or isolated about the grounds.

Rosa.

POTTING ROSES.

The present is a suitable time to pot some of the free-blooming Roses for forcing twelve months hence. Dwarf or bush plants from the open ground are by far the best for the purpose. If plants are purchased from a reliable source, taking care to order "selected for potting," this plan of obtaining a supply of pot plants will be found both economical and satisfactory. Some of the very freest bloomers, such as the *Monthlies*, in all their wealth of novel colouring, especially among recent novelties; the pretty little Dwarf *Polyanthas*, and some of the true decorative Teas and Hybrid Teas, such as *Papa Gontier*, *Caroline Testout*, *Liberty*, *Corallina*, *Augustine Guinoisseau*, *La France*, *Mrs. W. J. Grant*, etc., can be used to much advantage in the flower-garden in the summer, and especially are they useful to fill up beds in which late hollis have flowered.

This summer we so used plants of the *Crimson Chinas*, *Fabvier* and *Cranoisie Superieure*, plunging the pots quite below the surface of the soil. The plants blossomed gloriously. If given a good soaking before plunging, the plants apparently obtain sufficient water afterwards from the soil or rains. Another plan we have adopted with much success is that of removing the first crop of buds as soon as they are visible, at the same time cutting back the shoots an inch or two. This arrests the growth for a time, but very soon new growths start, these blossoming just as the first crop of outdoor Roses is waning.

Of course all these Roses are grown entirely out-of-doors the first year after potting. Our plan is to select good bushy plants of such sorts as we have found useful, trim back their growths to about half their length, and slightly trim the roots, then pot up into 8-inch pots, or at least 7-inch. A compost of loam and well-rotted manure is used, two parts of the former to one of the latter, and we also add crushed bones and wood-ashes in small quantities. Clean pots, plenty of crocks, and firm potting ensure success. We never attempt to force such plants the first year. Such as we do not set out as mentioned above are plunged in beds in a sunny position in June (having previously kept the plants sheltered by hedges), and they are then carefully looked over every day, to see no injury is done by too rapid evaporation. Weak liquid-manure is applied once or twice a week, when buds are of the size of marbles. On the H.P., H.T., and Tea varieties bloom of quite exhibition size are possible.

The amateur whose soil is quite unfitted for Roses may find in the plan advocated a means of growing a few beautiful Roses inexpensively, even if he does not require them for his greenhouse. Especially would I commend this practice to dwellers near large cities. Any handy man could construct a temporary glass-roof with which to merely shield the plants, and there is nothing to prevent him cleansing the foliage every other day from harmful deposits.

Rosa.

NOTES AND REPLIES.

Roses *Merveille de Lyon* and *Crimson Rambler*.—I do not think we fully realise the value of the Hybrid Perpetuals for not claim for them the

VEGETABLES.

SPANISH ONIONS.

Under this heading may safely be included a large number of forms differing very little, if at all, from each other, but all of good shape

continuous blossoming of the Teas and Hybrid Teas, but many, for the short time they are in flower, are unequalled for effective display. I have in mind some glorious bells of Merveille de Lyon, that stately sport from Baroness Rothschild. What a splendid contrast this Rose would be planted among pillars of Crim-

Onion Frown Spanish.

tively cold, wet autumn as well, half-hardy subjects, such as the one under notice, should severe frost occur, may suffer severely if left too long in the ground. Carrots are much harder, but it is advisable to lift maincrop varieties now growth is finished. Sowings made in July are best left in the ground, affording a light protection of half-decayed leaf-soil or Bracken should hard frost threaten. I have stored both Beet and Carrots under a north wall, stacking the roots close up, sprinkling a little dry sand or ashes over each layer, keeping the crowns outward, and nailing overhead a flat board to carry off the rain, and in the severest winter placing a thick layer of straw in front of the stack. Here the roots kept very plump and no growth set in until quite on in the spring. The roots remaining so dormant must of necessity be of much better flavour than those that require to be rubbed over two or three times during the winter. The cooler these eatable roots can be kept after housing the better, care being taken that mice do not work them, which they often will during hard weather. Veitch's Model Carrot is hard to beat for a gentleman's table, having such a small amount of core, while for the July sowing I rely upon this variety and Sutton's Early Gem. EAST DEVON.

SEED POTATOES IN WINTER.

When Potatoes are being grown or harvested much anxiety is shown in regard to their welfare. But when under cover it is thought they are right for months, and little or no concern is felt for their safety or attention devoted to the care of the seed so long as it does not actually decay. In my opinion, however, great benefit results from attending well to seed Potatoes in winter, no matter how sound they appeared to be when stored. In looking them over once a month or so until planting time, it will be found that some of them are decaying. When stored in heaps, as they have to be in many instances, one or two decaying in the centre, and allowed to remain there, will soon cause others to perish. This must be guarded against where sound seed is valued, and a general turning over and picking out of bad tubers at frequent intervals are the only way to keep the seed in good condition. Small and medium-sized tubers generally keep better than very large ones, and those who selected their tubers at digging-up time will have fewer decaying ones amongst them than if the whole—large and small—had been stored up together. Seed Potatoes may be kept very well in the

and very serviceable. Well grown, early matured bulbs of the Spanish types of Onions present a very clean appearance, the necks being small, but, as a rule they are somewhat flat, and often rather hollow underneath; consequently they do not weigh particularly well, and lose ground in competition with the newer forms of a different type with well rounded bases. They also do not keep over well. If well harvested, bunched, or roped up, and kept cool and dry, they may last till March, but seldom beyond that date.

BETROOT AND CARROTS.

These two roots should be lifted and stored early in November, especially Beet, though this will withstand more frost than a great many

son Rambler! If the latter were disposed thinly, so that each pillar developed in its own glorious fashion, a number of Merveille de Lyon could be planted quite thickly to give the best contrast, for this Rose may be hard-pruned to much advantage. If two or three yearling growths are retained, and these cut back to five or six eyes, a truly glorious blossoming is secured. I think some of our public park managers should grow Roses more than they do. The expense and trouble would doubtless be greater, but our national flower seems to be almost ignored in such places.

Roses for cold greenhouse.—1. Kindly give me the names and colours of the most satisfactory Roses for pots in a small cool-house? I only want blooms for use in the house without any, or with very little, expenditure of fuel. 2. Names and colours of climbing Roses for the iron pillars of a large cool-house, where I propose growing Figs, Cherries, etc., in pots, utilising the roof supports and end wall for Roses? The house being very sunny the Roses would be early in bloom, I hope. 3. Advice respecting a long, single trellis, iron, small beds at foot of trellis; intervening arches have flower-baskets; lawn in front; bed between back of trellis, and a Box hedge about 3 feet behind; the whole rather shaded by trees behind hedge, and having an east aspect. The house shades from the south, but it is open towards the north. A Crimson Rambler Rose is doing well over one arch, but everything else is stunted, and there is really nothing to clothe the arches or trellis, which I wish to transform into green arches with always blossom somewhere for many months. I will be grateful for suggestions.—A. H. F. M.

[The Hybrid Perpetuals and Hybrid Teas furnish us with the best Roses for this purpose. Of the former the six best are Mrs. John Laing, pink; Ulrich Brunner, red; Captain Hayward, crimson; Senateur Vaisse, crimson; Merveille de Lyon, white; and Suzanne M. Rodocanachi, salmon-rose; and of the latter, Caroline Testout, pink; Belle Siebrecht, deep pink; Aurora, rose; La France, pink; Augustine Guinoisseau, blush white; Marquise Litto, vermilion-red; Viscountess Folkestone, cream; Grace Darling, pink and yellow; Mme. Ravary, yellow; Liberty, crimson; White Lady, creamy white; Mme. Cadeau Ramey, yellowish-white; Mme. Jules Grolez, silvery-pink; and Lady Battersen, red. For the fruit-house pillars you could grow Climbing Belle Siebrecht, pink; Billiard and Barré, rich yellow; Cheshunt Hybrid, red; Gloire de Dijon, buff; W. A. Richardson, orange; L'Idéal, coppery-red; Dr. Rouges, red-yellow; Purity, white; Mme. Moreau, orange; and Mme. Abel Chatenay, vermilion-rose and salmon. For climbing on trellis with east aspect you require good, sturdy subjects. The yellow Rambler Aglaia and the white Rambler Thalia would flourish, but I would Felicité-Perpetue and Flora.]

Onion White Spanish.

imagine. The foliage is a great protection to the roots, but it is unwise to leave them in the ground long after November comes in, as they will get sharp touches of frost, and this season, owing to so little sun and a compar-

dark, but they will do equally well, and often better, in the light. The objection to a dark, close place is its tendency to force the tubers into growth. The shoots of many are rather liable to start prematurely under all conditions,

but they are less so when kept cool and in the light. Robust green shoots will never push out so rapidly as drawn-out white ones. The latter are absolutely worthless, and should never be encouraged. When they grow to any great length the seed cannot be planted with them attached to it, and in breaking them off a good deal of harm is done. The best of all seed Potatoes are those which never require to be disbudded. The first shoots or main eyes are the strongest as a rule, and when these have to be broken off owing to coming too soon, those which follow are always weaker; and if the seed can be stored so as to retard growth until as late as possible, and then produce it of a robust character, strong stems and a good crop are sure to be the result. Some of the best Potato growers never put one of their seed Potatoes on the top of each other, or more than two layers deep at most, and this is a good way of storing seed in winter. As the shelves in fruit rooms are emptied they might be profitably refilled with layers of the best seed Potatoes, and any spare rooms or lofts may be used in the same way—cool places, well lighted, but free from frost. In mild weather a good deal of air should be admitted, and in times of severe frost they should be covered up in some way. T.

CAULIFLOWER.

THE last week in August, or even the first week in September, will be found a suitable date to sow seeds to supply heads for next June, early or late, according to the season. Drills, 1 foot apart and shallow, should be drawn, choosing a sheltered corner for the purpose, moistening the same before sowing the seed, if at all dry, and covering with the dry soil got out. Keep a sharp look out for slugs as soon as the seedlings appear, dusting with freshly slaked lime occasionally will usually ward off slugs. When large enough to handle the little plants should be dibbled out into nursery lines, 6 inches apart, in cold pits or where two or three light shallow frames can be placed over them when much frost threatens, or plant in batches of five, where they can be covered with handlights or cliches later on. The one aim the gardener has is to keep them as hardy as possible, and even when the lights have to be put on in severe weather it is wise to leave a little ventilation on, or the plants are inclined to get spindly and weak, consequently they soon succumb when much frost lays hold of them. In this favoured part of the country, seed sown on the 9th of September, and duly pricked out 6 inches apart each way on a very warm sheltered border, withstood the winter safely without any protection whatever; these planted out in the open garden towards the middle of March gave us remarkably good heads about the middle of June, the variety being Early London, followed by the same variety and Autumn Giant, sown in a little heat at the beginning of February.

EAST DEVON.

Weeds in kitchen garden.—Weeds have been allowed to get the upper hand in my kitchen garden, and my gardener has merely dug them in whilst digging—that is, he has bodily turned the clod of ground over so that the weeds are inverted and underground, but still rooted and undisturbed. Will they grow through surface again? They are not more than 5 inches or 6 inches below surface. Would it have been better to grab them out, burn them, and use the ashes for manure?—R. L. Y.

[You ought to have trenched the ground deeply, burying when doing this the weeds; or you could have hoed up the weeds, gathered them together, and burned them with any other rubbish you collect in the garden, such as pruning of trees, vegetable refuse, etc., and then spread the ashes on the ground.]

Peas falling.—I cannot grow Peas in my garden. Can you help me by telling me whether I could find out the cause by getting the soil analysed, and whether in that case it would be likely that I could alter it effectually? I have tried lime and plenty of good manure without success. Then, last summer, I had some soil carted from a distance where the soil was different, and filled a trench some 2 feet wide and 2 feet deep with it. There I had a good crop, but the other rows were failures as usual.—E. W. L.

[From your letter we should say that the ground wants trenching to a depth of 18 inches or 2 feet, incorporating as the work goes on plenty of manure. If your soil is light, use cow manure, as this helps to retain the moisture, but, if heavy, then stable manure will answer. What you want is depth of soil, as is apparent from the crops you had when you added the fresh soil by the depth of 18

inches. Have the ground trenched and manured at once, allowing it to lie rough until you wish to sow your Peas.]

GARDEN WORK.

Conservatory.—Damp is the great enemy now, and the chief thing to aim at is to keep the atmosphere sufficiently dry without using too much fire-heat. Careful watering and efficient ventilation will do much to preserve the flowers—especially Chrysanthemums—in condition as long as possible. Except in wet, windy, or frosty weather, the ridge ventilators should never be altogether closed. This will prevent the moisture condensing on the glass and dripping about among the flowers. There will be more or less warmth in the pipes, according to the atmospheric conditions outside, so that the air may always be kept in circulation. Small or moderate-sized blooms keep much longer than large ones which have had a period of high feeding. If one intends to exhibit Chrysanthemums, the cuttings must be struck early—i.e., from the end of November to the middle of January. A strong, healthy cutting rooted in January and grown on steadily will make a better plant and produce larger blooms than a weakly cutting struck in November. But if we do not intend to exhibit, then take strong cuttings whenever and wherever they are to be found, between December and April, or even later, if plants are wanted for grouping in 6-inch pots, carrying one good bloom. I have had very good blooms on seedlings, of which the seeds were sown in February and grown on in heat till April, and then hardened off and placed outside. Seedlings from a good strain make useful decorative plants, though one might never raise a plant good enough to obtain a certificate. Camellias, if the growth was made early, will soon be showing colour; but Camellias are not wanted till the Chrysanthemums are nearly over, and by that time one begins to long for Camellias, Azaleas, Genistas, and the usual winter-flowering greenhouse plants; and later on will come the forced things—bulbs, Lilacs, Spireas, etc. Lilacs force very well in the dark till the flowers are ready to expand, and if the blooms are wanted for cutting only, they must be pushed on rapidly in the dark. I have had them in the Mushroom-house till the flowers opened, and then placed them under glass, shaded for a time.

Forcing-house.—There is always work to be done in a forcing-house at this season. Things move slowly now, and a start should be made with flowering plants, such as Azaleas, Spireas, Lilacs, Tea and other Roses, etc. Double Daffodils that were potted in August are moving. Arum Lilies may have liquid manure as soon as the pots are full of roots. Lillium Harris is growing freely and must have all the light possible to keep the plants dwarf and robust. Do not use too much fire-heat; 60 degs. at night should not be exceeded at present. They will respond more freely to a little more warmth when some progress has been made. It may be mentioned that it is of no use to force anything that has not had at least twelve months' preparation.

Forcing pot-Vines.—Strong well-ripened canes of Black Hamburg or Foster's Seedling Grapes may be started any time now in a temperature of 50 degs. If there is a bed of leaves in the house the pots may be plunged in the bed to encourage the roots. The rods should be trenched down to induce back eyes to break regularly. As a rule, when the wood is well ripened and the atmosphere is kept moist by using the syringe, there will be no difficulty in inducing the buds to burst strongly and produce fruit. Very little ventilation is required until the leaves are expanding so far as the Vines are concerned, but, as a rule, when the pot-Vine-house is started there are other things in the house besides the Vines, and the matter becomes a compromise between the Vines and other things, and the best should be done to meet the wants of all things. A good deal of work may be done in a small forcing-house besides forcing a few Grapes in it. If the garden is in the hands of a good man 50 degs. at night will do till the leaves are bursting forth, then raise to 55 degs. and

as the development goes on and the bunches become visible, increase to 60 degs. and advance to 65 degs. when the Vines are in bloom. The last figure should not be exceeded, and this means that the thermometer will fall to 60 degs. about sunrise in the morning. As soon as the Vines are showing colour in the foliage, ventilation will be carefully attended to, beginning in a small way early in the morning and closing early in the afternoon.

Forcing Asparagus.—With plenty of strong four-year-old roots which have been permitted to grow freely, and next to nothing cut therefrom, there will be no difficulty in cutting Asparagus in three weeks. The simplest way of forcing is to make up a bed of leaves and manure in sufficient bulk to produce a warmth of 75 deg. to 80 deg., or even a little more, but a very strong heat is not desirable, as hard forcing weakens the growth. When the bed is in a suitable condition, the roots are taken up and placed in the frames, close together, on a layer of leaf-mould 2 inches thick, and a covering of 6 inches of light sandy soil is placed over the roots, and a good soaking of warm water given to settle it down. A watch-stick is then placed in the frame to tell the temperature from time to time. The frame is matted up till the heads of Asparagus are coming through the soil, when light and air may be gradually admitted. Asparagus may be forced in boxes or flat baskets in a dry, warm house. It may be started in the Mushroom-house; and we have often forced it in shallow boxes in a Cucumber-house.

Early Potatoes in pots.—Good sets of Duke of York or any other early kind may be started in pots—three sets in a 10-inch pot in a dry, light house. Place some drainage in the pots, and use sandy loam and leaf-mould or very old manure, such as is usually found in old hotbeds. Only one crown eye should be left to each set, as one-stemmed plants are earlier than when more stems are left, and the tubers are more even in size.

Window gardening.—Cactuses will require no water now till the days begin to lengthen again. Geraniums and other plants in a cool room will require very little water now. Palms and other fine foliaged plants may be frequently sponged, and, when dry, sufficient water must be given to moisten all the roots. Hyacinths coming on in glasses must have the water renewed as required.

Outdoor garden.—This is the season for tree-planting, and a little more variety may be desirable in many places where there is space to plant. The Scarlet Oak is a grand tree when it has attained size. The White-leaved Poplar (*P. Bolleana*), is a very handsome and distinct tree. The Birch is a very charming tree, either isolated or in groups. Planted thinly among Rhododendrons with clumps of Lilies of various kinds it has a pretty and interesting effect. There is more variety in Beeches than is generally supposed. Several years ago I obtained a collection from a continental nursery, and though there was a good deal of sameness among them the collection was interesting. Everybody should plant at least four varieties—the common Silver, Young's Weeping, *laciniata*, and the Purple-leaved variety. The Purple Beech, of course, everybody plants, and the Fern-leaved Beech is an interesting tree. For exposed positions the Austrian Pine is excellent, but buy the trees from a nursery where things are regularly transplanted, and do not have them too large. For wind-swept places our native shrubs and trees are indispensable. Hollies, Yews, and Boxes are thoroughly reliable, and there is a good deal of variety, especially among Hollies. Winter residences should have abundance of Hollies about the grounds. Among Conifers the Cedar of Lebanon and the Atlantic Cedar are exceedingly hardy and useful trees, either for avenues or grouping, or as isolated specimens on the lawn.

Fruit garden.—The weather has been very suitable for pruning and planting, and every effort should be made to get this work forward before Christmas. There is not a shadow of a doubt if we want handsome Apples quickly after planting, we must plant dwarf trees on the English Paradise stock. The finest Apples at the shows are of the

bush trees. Plant from 10 feet to 12 feet apart, and if there is any idea of marketing any of the fruit, do not plant many kinds. Probably six kinds would pay better than more, and at any rate I should not plant more than a dozen. Do not forget Newton Wonder. Bleheim Orange is a good Apple for those who can wait, and Cox's Orange Pippin for a warm, deep loam. One of the things which many people forget is to feed the trees when they are bearing freely, and a top-dressing of really good soil with a little bone-meal added will encourage the roots to remain near the surface, and that is the chief advantage of the surface-rooting stock. Do not plant anything within 4 feet of a fruit-tree. Even more space should be given, if possible, to wall trees. When the wall borders are cropped close up, the trees must suffer. In planting, be careful not to bury the collars of the trees. We may plant a Rose on the Manetti deep enough to cover the stock, but fruit-trees must not be buried.

Vegetable garden.—When taking up Sea-kale for forcing, trim off the rootlets or thongs and cut them into sets, 4 inches or so long, and lay them in damp sand or earth till February or March. By that time they will have formed small crowns at the thick end of the thong or cutting, and when planted, green leaves will soon appear. A little later the crowns can be thinned to one on each root. If planted in good, well-worked land early in March, in rows 15 inches apart and 12 inches apart in the rows, good crowns suitable for forcing will be obtained by the autumn. Up to the present there has been no frost. In many gardens Cauliflowers are abundant and fine, and French Beans, in some warm situations, are still untouched by frost. Of course this cannot continue, and in the event of a sharp snap coming suddenly the tender things must be sheltered. Lettuces in the open will land a very poor chance, and Cauliflowers unprotected will soon become a brown slimy mass. All root crops in the ground which are likely to be injured by frost should be lifted at once. Parsnips and Jerusalem Artichokes will do no harm. I have heard several people praise the Chinese Artichoke, but though it is a right the roots are too small to be enthusiastic about. E. HOBDAV.

THE COMING WEEK'S WORK.

Extracts from a Garden Diary.

December 1st.—We have still some pruning to do, and many wall trees to train. For this latter work we find the Golden Osier or Willow very useful for securing the large branches, and as the Willows are plentiful on the place, there is economy in using them, and many of the ties will last two years, which is quite long enough. Took up Rhubarb for forcing in the Mushroom-house. Started a few sets of early potatoes for frame planting. We find beds of ashes and stable-mannure very suitable.

December 2nd.—We have just finished planting Roses, except a few Teas which are in pots and will be kept over till the spring. We have planted Roses much later than this, but there is an advantage in getting the planting done as near November as possible. The early-planted Roses have begun to make roots, and will soon be well established. We have potted a good many of our old scarlet and other Geraniums. Most of the largest leaves were cut off, and the plants when potted were placed in a temperature of 50 degs. Every plant is now making growth, and there will be good stock of cuttings.

December 3rd.—Some common things, such as Laurels and Oval-leaved Privets, have been removed from a recently planted shrubbery for the future we shall discontinue the planting of nurses, but fill in between the permanent features with herbaceous plants, such as Michaelmas Daisies, toll Phloxes, etc., in groups of one colour, and by the sides of the walks, or within sight of them, do more with bulbs and Primroses. Planted a group of Silver Birch at one corner of a lawn. A group of three trees of the Scarlet Oak has also been planted.

December 4th.—Started a fresh lot of Sea-kale roots in the Mushroom-house. Everything is sweet in the Mushroom-house, where Rhubarb

and Sea-kale are being forced, or the flavour may be injured. Rhubarb especially will take on an earthy flavour if grown in a tainted atmosphere. Tree Carnation Alma Franco is a vigorous, healthy winter bloomer, and is easily propagated from cuttings in heat in February. Looked over fruit stores. The finest and best Apples have come from the bush-trees on the Paradise-stock. These are freely top-dressed with rich compost.

December 5th.—All our hulk-beds and borders have been top-dressed with a mixture of old potting soil and Moss-litter-manure. This will remain till the bulbs are coming through, and will then be lightly buried. Last year we noticed some of the large patches of Narcissus in the wilderness failed to bloom well. These, when the growth ripened, were lifted, and were found much too thick to flower well. The bulbs have now again been planted thinner in fresh soil, and we hope to see them flower abundantly again.

December 6th.—Rearranged conservatory, and removed all plants no longer effective. We have still plenty of Chrysanthemums; some of the late sorts are only just showing buds. Besides these, Scarlet Salvias and Scarboro' Lilies in quantity are very bright. Then, in addition, there are numerous odds and ends of things which come and go constantly, and help to give variety, and we know how charming variety is in a conservatory. The watering is always done in the morning now, and a little ventilation given at the same time to get out the damp.

BEEES

Foreign Bees.—C. J. Padbury, in writing to you about foreign Bees, November 14, p. 492, says, "I did not get Carniolans, as they have a bad name for swarming." I have had several stocks of Carniolans for some years, and find that they only swarm in alternate years. The year that they swarm I get no super honey. They are in Neighbour's Cottage Hives, with glass windows to the side, and I put bell glasses and box supers on the top, which are well filled every other year. One hive is octagon-shaped, and has a large octagon wood and glass super to fit it, which holds 35 lb. I have twice had this quite full. They are extremely hardy Bees, and I never feed them. They are also excellent workers, and I am never without super honey from one or other of the stocks that have not swarmed during the summer. I had English Bees at one time, but I find the Carniolans more hardy, strong, and healthy, and certainly better workers.—E. GODOLPHIN OSBORNE, Cotswold District, Gloucestershire.

BIRDS.

Bullfinch (E. S. W.).—Yes; it is bad for any bird to be kept in a room where gas is burned, and Bullfinches being very susceptible to the influence of heat, which affects them injuriously, require to be kept in a cool atmosphere to preserve them in health. Your bird could not have had better treatment in the matter of diet, and there can be little doubt that the gas was the cause of its death. You, of course, supplied it with grit, sand, and plenty of water. Besides causing the loss of feathers through skin irritation, the heat from gas brings about what is commonly called by bird-keepers asthma, but which is really an irritation of the bronchial tubes from the influence of the hot, dry air. A good diet for Bullfinches is black Rape-seed, scalded, to which should be added a little Canary-seed, and just a few grains of Hemp occasionally. These birds in their wild state are very partial to buds of fruit-trees, and in a state of captivity should be supplied from time to time with a small bunch of twigs of any kind of fruit-tree, which will tend to keep them in health. A piece of Apple to peck at is greatly appreciated by these birds, especially if it contains pipe, of which they are exceedingly fond. They may also have occasionally a stalk of Platinaid-seed, a few Privet berries, a piece of boiled Carrot, and a little Watercress to pick at.—S. S. G.

Death of Hartz Mountain Canary (Nite).—This bird was excessively fat, and its sudden death appears to have been due to an apoplectic seizure, which is often the fate of a bird in this condition. This over-fatness may have arisen from its having partaken freely of food too rich in nitrogenous compounds, and the Maw-seed was probably the cause of the trouble. A constant supply of this seed should not be allowed, but only a small quantity occasionally. When constantly given, although it be mixed with the other seeds, Canaries are apt to consume an undue proportion, and suffer accordingly. On the shortness of breath being observed it would have been well to have put the bird upon short commons, and to have discontinued the Hartz Mountain bread and Maw-seed for a time, while encouraging the sufferer to take as much exercise as possible. There is always a disinclination on the part of a bird suffering from obesity to move about or take sufficient exercise, which, of course, increases the trouble. Where plenty of exercise can be obtained, as in a garden aviary, birds remain in perfect health, and may be allowed to indulge freely in various seeds that would prove injurious to caged birds. The plumage of this Canary was in very fine condition.—S. S. G.

AQUARIA.

Wintering Goldfish ("Yewcliff.")—These fish will survive the winter in ponds if the precaution be taken, in the event of frosts, to keep the ice broken in places to admit air. It would, no doubt, save much trouble and anxiety to winter your Goldfish under cover. A greenhouse with a temperature of from 50 degs. to 60 degs. would suit them well, but care must be taken to shade the water from the direct rays of the sun, for, although light is necessary to the production of oxygen and to the growth of aquatic plants, an excess of light encourages the development of conferva, which not only appears on the sides of the aquarium, but will grow also upon the stems of aquatic plants, besides making the water thick and unpleasant to the eye. For food give your fish a little vermicelli now and then, broken rather small, and a tiny worm or two occasionally. Dried leaf beef, shredded very fine, is an excellent food for Goldfish; they devour it greedily, and thrive upon it exceedingly well.—S. S. G.

LAW AND CUSTOM.

Quitting tenants and fruit-trees.—I am changing my residence. Have I the right to take away with me the fruit-trees, Strawberry plants, Raspberry canes, Rose-trees, and the flowers which I have planted?—Z. Z.

[No; you cannot remove any of these things. When once planted, such are annexed to the freehold and belong to the landlord. But a landlord will usually allow a tenant to remove flowers, if permission be asked. He may refuse if he thinks proper so to do.—K. C. T.]

Ruinous property left to tenants for life.—Some time ago some property was left to my sisters for their lives only. It was then in such bad repair that a half-year's rent only did a small part of what was necessary. It is in a very bad state, and the heir refuses to assist. If my sisters have to put it into anything like decent repair, it will absorb the whole income they derive from it. Could they borrow on mortgage for the purpose of repairs without the consent of the heir? The property was left to my sisters to maintain them.—GLINDALE.

[This question should be asked of a solicitor who can inspect the will under which the property passed. Without knowing the terms of the devise it is impossible to say what powers the sisters possess to charge the property. They may certainly mortgage their own interests, but as the security would be questionable, this course might not help them much. You should consult a solicitor.—K. C. T.]

Position of an outgoing tenant.—On April 8th last, I took a house, with a small garden, comprising some 200 square yards, in the front. On half of this garden there then stood 100 Rose-trees; the other half was Grass. I paid my landlord on my entry £4 for the Rose-trees in question, and I sent the note he gave me to Somerset House, and had it stamped there. I have received notice to give up the garden on Feb. 2, 1903. Can I sell the Rose-trees to the value of £4 and remove the remainder?—BEGONIA.

[Your statement is incomplete; you should have sent a copy of the note the landlord gave you, and you should have said whether there was any understanding that you were to be at

Lants are divided by the inexperienced. Treated as above, however, the operation may be performed expeditiously and well. Hardly any other hardy plant possesses so much a trunk root as the Peony, and especially so if the plants are of long standing. A good deal of the hard trunk portion is quite useless, as no fresh root-fibre is emitted therefrom. After division of this kind the plant recomposes its rooting from the base of the crown-luds.

Standard Heliotropes (Norwich).—The tall heliotropes seen in many public parks and gardens are grown on from strong cuttings, rooted early in the spring, these make quick growth, and in heat throw up one ending shoot. As side shoots break these are pinched off, and when bloom shows in the leader, that too is shed and a fresh leader formed. This process being repeated until the plants are 4 feet in height. They are readily induced to grow up to this height if they are kept in pots in a greenhouse, where they get abundance of light and air, also plenty of water, with occasional doses of liquid manure. Once the plants have attained the desired height, they are in the spring following started to grow up under glass, then hardened off, and early in the year are put out into the beds or plunged in the lawn. It must be taken that the plants do not suffer from frost during the summer, an occasional dose of liquid manure being also very beneficial.

VEGETABLES.
Wireworm in garden (Despair).—You should try at once a dressing of gas-lime at the rate of one cwt. to three rods of ground. When the ground is dry, spread the lime about as evenly as you can, and expose to the air for four or five weeks it will kill down and may be spread more evenly. Then dig it in. Simply allow it to be washed in until the worms come off the ground, then dig it in. Ground dressed must not be cropped until the spring.

Overcing Rhubarb in the open air (F. R.).—Use some pots or boxes with morable tops, and place the crowns to be forced. Then cover them all with fresh stable litter, or a coating of leaves and mixed together. If you want Rhubarb by Christmas you must cover up some crowns at once, and as soon

as the first batch has started into growth cover a few more crowns to keep up a succession until Rhubarb comes naturally in March, when a little litter spread over the crowns will forward the growth at least a fortnight before those that are left uncovered.

SHORT REPLIES.

Wm. Pinford.—The remoral has checked the flower. See notes on Calliolas in our issue of Nov. 23, p. 496.—**S. H.**—The dates are wrong. The "Week's Work" is concluded from one year's end to the other. We always go to press a week in advance—that is to say, the issue for the 22nd went to press on the 15th.—**O. Durrell & Co.**—1. Yes, you can keep the Maiden-hair in your conservatory during the winter, but you must not give it much water from now until the end of March. 2. Leave the Rose as it is. It will stand in the cold-frame all the winter. 3. Pot Palms in the spring, using good yellow loam with plenty of sand mixed with it.—**Madame Ligonier.**—Do you mean early-flowering Chrysanthemums? If so, lists and full descriptions have been given in recent numbers.—**J. Atkins.**—"Chrysanthemums and Their Culture," by E. Motteux. Fourth edition.—**Books.**—Any nurseryman will be pleased to send you his catalogue.—**Herb r.**—Water the plants with weak lime water, when the worms will come to the surface and can be destroyed.—**R. B. Johnson.**—Yes, any of the plants mentioned in the list on p. 413 will answer your purpose. Any tree and shrub nurseryman will supply you.—**Case.**—We do not undertake your query.—**H. G., N. Devon.**—See letter in this week's issue on the subject, p. 510.—**Carl Hill.**—3. The way is to plant groups of six or more, according to space, and not to have single specimens all over the border. See article in this week's issue, p. 510.—**A. R. C.**—If shoots are very thick, thin them out in order to strengthen them.—**W. J.**—You will make good cuttings. 2. Do you mean Viola (Tufted Pansy) seed?

NAMES OF PLANTS AND FRUITS.

Names of plants.—**F. L. S.**—1. Pentstemon var.; 2. Specimen insufficient; 3. Phlox Drummondii.—**E. S. Rogers.**—1. Nephrolepis exaltata; 2. Asplenium bulbiferum. We cannot undertake to name Rosea.—**K.**

Tracks.—**Cereus** sp., but cannot say which without seeing flowers.—**W. H. B.**—1. Eucynina japonicus latifolius albus; 2. Begonia, belonging to the Rex family; 3. Asparagus Sprengeri; 4. Adiantum contentum latum.—**F. J. R.**—Kindly send in flower.—**Tate.**—1. Chrysanthemum Pygmalion; 2. C. Prince of Orange; 3. Aster cordifolius.—**G. Jones.**—1. Hypericum calycinum; 2. Marvel of Peru (Mirabilis Jalapa); 3. Anemone; 4. Ground Ivy probably.—**W. J.**—Difficult to say from leaves only, which resemble those of Cassia floridana.—**Kerr.**—The Tamarisk (Tamarix gallica).—**R. H. D.**—1. Sedium rupestre; 2. Sempervivum montanum; 3. Saxifraga hypnoides; 4. Veronica repens.—**R. T. S.**—1. Begonia metallica; 2. Linaria reticulata alba; 3. Diplacus glutinosus.

Names of fruits.—**C. A. S. M.**—Pear Doynend du Comice.—**Kelax.**—Your Apple is, we think, the French Crab, but it is difficult to say when only one specimen is sent. Try root pruning the tree to bring it into bearing.—**M. E. R.**—Pear Cassane.—**Lillo Book.**—Specimens insufficient.—**Atwell.**—Apple Yorkshire Beauty. Pear, specimen insufficient.—**Hoare's Plum.**—Pear Louise Bonne of Jersey.—**Springfield.**—Pear Hurst's Prince Consort.—**C. J. R. Plus Beau.**—1. Reinette de Canada; 2. Hambleton deux Ans; 3. Alfriston.

Catalogues received.—John Farley, Hawick, N.D.—List of Trees, Shrubs, Fruit-trees, etc.—Hogg and Wood, Coldstream and Duns, N.B.—List of Nursery Stock.

National Dahlia Society.—The annual meeting of the Society will be held at the Hotel Windsor on Dec. 10. The first exhibition will take place on Sept. 1 and 2, at the Hotel Hall, Westminster. There will be a conference on the judging of Cactus Dahlias on the afternoon of the first day. Lord Helchester has kindly consented to become a patron of the society.—**J. F. H. Ross, Hon. Secretary.**

Photographic Competition.—We beg to remind our readers that the Photographic Competition closes to-day, and all intending competitors should send in at once.

AN ENTIRELY NEW DICTIONARY OF GARDENING. JUST PUBLISHED.

Complete in TWO VOLUMES. Half-leather. Gilt Top, price 30s. net.

Cassell's Dictionary of Practical Gardening.
An Illustrated Encyclopædia of Practical Horticulture for all Classes.

Edited by **WALTER P. WRIGHT,**

Agricultural Superintendent under the Kent County Council, Author of "Pictorial Practical Gardening," Editor of "The Gardener," etc.

With COLOURED PLATES and several hundreds of Illustrations from Photographs taken direct from Nature.

"The Dictionary has the merit of being wholly distinct from all other gardening books, encyclopaedic or otherwise, and, what is of still greater importance, is so admirable in plan and execution as to leave no doubt in our mind as to its proving highly useful and attaining to a degree of popularity."—*Gardener's Magazine.*

Patent Greenhouse BOILERS.

The special merits of our Boilers are—
 1.—Long Burning.
 2.—Even Temperature.
 3.—No Trouble.
 4.—The Feeders being hinged can be pulled forward when desired, completely exposing fire-box.

In these particulars our Boilers are beyond competition.

Guaranteed Minimum Burning 12 Hours Without Attention.

It goes without saying that the large reserve of fuel in the Feeder insures burning for at least four times longer than is possible with ordinary boilers. Unsatisfactory Boilers can be replaced in a few hours' work without moving existing pipes.

EXTRACTS FROM LETTERS RECEIVED:

"My gardener says he never had such a stove before, so easy to work and does its work so well." "Does its work splendidly, and is certainly the least trouble of any stove I ever had." "My maid manage it." "The last No. 2 I had from you always goes 24 hours at a stretch." "I never look at it but once a day, and have a good even heat the whole 24 hours."

VEGETABLES.

LUXURIANT WINTER GREENS.

There seems to be in every direction robust, indeed luxuriant, growth on the part of all winter green stuff. Very much of it, especially Brussels Sprouts, Savoy Cabbages, and Cole-cabts, are too gross and early, and are hearting otherwise turning in much before wanted. The season was so favourable to growth that plants put out as usual in the summer met with no check, and now that the autumn is proving to be open and mild, growth is really luxuriant. Did we have no severe weather other than no harm would result; but we cannot expect to get through the winter without experiencing some severe frosts, and a few of these would do these coarse, sappy greens great harm. Those who planted later, say in August and September, preferring to have plants less gross, therefore much hardier, and coming in later when most needed, will get one of much the best. The chief danger now is with white Broccolis, which are always the more susceptible to injury the grosser in growth they are. All these will be benefited had hardened if they be laid over on to their sides in their rows, beginning at one end of each row and tilting the plants over on to their sides all one way with the aid of a fork, then dropping a spit of soil on to the stem to keep each one prostrate. Any others, whether Cabbage, Kale, Sprouts, or what not, can be checked by partially lifting them with a fork from out of the ground, so as to materially disturb the roots, then dropping them into their places again. Generally, in putting out winter green stuffs sowings are made too early. It is all very well to get Giant Cauliflower and some Brussels Sprouts seed sown in March, but for Kales, Savoys, late white and Sprouting Broccolis, and late Brussels Sprouts it is better to make sowings in May and June, as it should be the aim of the grower to cater more for the second half of the winter than the first half. Some things, especially white Broccolis and Brussels Sprouts, put out on to hard ground after Strawberries or Onions, often become all the hardier. A. D.

VEGETABLE REFUSE.

The value of a plentiful supply of manure is known to all gardeners, and as stable-manure is not always available for dressing the land, recourse must be had to other ways of obtaining the requisite amount of fertilising material. Vegetable refuse, of which a great deal is formed throughout the year, but especially in the autumn and early months, may either be allowed to go to waste or it can be converted into valuable manure. Of the materials which come under this heading, tree-leaves are amongst the most valuable. Now is a good time to collect them for the purpose in view. In doing this in parks and pleasure grounds they are sometimes thrown here and there, or

where, so long as they are out of sight, and when deposited in this way they ultimately form small heaps of decayed matter which may be removed and used for some purposes in the garden in spring, but this kind of material alone is never good manure, and cannot compete with specially prepared refuse. As the leaves are gathered they should all be taken to that part of the garden set apart for manure heaps, and this spot should be a general receptacle for them throughout the collecting period. At the same time all old Pea-straw, decayed leaves, and all kinds of Cabbage and Cauliflower-stumps from which the heads have been cut, should be brought from the kitchen garden and thrown into a heap close to the leaves. Light stable manure should also be brought here, and, indeed, everything else in the way of refuse. The whole should then be mixed up in one large heap to decay. As there may be a good deal of matter which would not readily decay, it is a good plan as soon as the heap has been made up to make the top of it a receptacle for all kinds of slops and soap-suds from the dwelling-house. This will enrich the leaves and induce decomposition. In about a month the whole should be turned over, keeping the freshest of the material at the bottom and the most decayed on the top. By January or throughout the spring this will make one of the finest heaps of manure anyone could desire for digging or trenching into vegetable quarters or dressing flower-beds.

All the year round it is a good plan to make a point of gathering every kind of vegetable refuse in a heap by itself, and it is surprising how valuable it will be found in the course of time. Weeds or any other refuse containing a quantity of seed which would germinate in the ground where not wanted should never be mixed up with anything useful.

TRENCHING AND DIGGING.

TRENCHING is a matter of much importance in the treatment of garden ground, particularly that part devoted to vegetables, and it ought to be done well and wisely. It requires both judgment and experience to decide how much, if any, of the subsoil should be piced upon the top. Subsoils vary so much that no certain rule or correct guide can be laid down upon this point. There is one operation that is applicable to every variety of subsoil (which neglected no trenching can be said to be efficiently carried out), that is, loosening and breaking up the bottom of the trench. The more thoroughly that is done the greater will be the ultimate benefit resulting therefrom. Another very important point to be considered is the proper season in which to trench. No doubt autumn is the best time for such work, and the earlier it is done the better, before the surface soil parts with the heat obtained from the summer sun. The next consideration of importance is the

APPLICATION OF MANURE during the operation of trenching. Many people never trench in manure, whilst on the other hand, some think it best to do so. If manure be buried deeply

in the trench it is well to use it in the green state, thus giving the ground the full benefit. If trenching be done in the autumn the manure will by the following summer be decomposed, and should the weather then be dry, deep-rooting plants will very soon go in search of it and be greatly benefited thereby. There are, however, people who prefer putting the manure near the surface, with a view to benefit the soil underneath by the washing in of the manure by rain. This question, however, must be settled according to opinion or circumstances. The

PROPER DEPTH TO TRENCH must depend upon the natural depth and character of the soil, and also the depth that has been gone to in previous trenchings. If the subsoil be bad, no portion of it should be brought to the surface, but a few inches of it may with advantage be stirred and left there for a time, and the essence of the manure washed down by rains becomes mixed with, and gradually improves, it by the time the land again requires trenching. In two or three years these few inches of bottom-soil can be brought to the top, and a little more of the bottom loosened up and left as before. Where the subsoil is ordinary clay, a couple of inches, at this and every subsequent time the land is trenched, may with advantage be brought to the top; but where this is done the work should be carried out in the autumn or early winter, so as to allow of the clay getting mellow and in a fit state to be forked in previous to the time of cropping. In digging or trenching in autumn and winter the ground can scarcely be thrown up too roughly. As large a surface as possible should be exposed to the action of the atmosphere. No time should be wasted in attempting to break it down; rain and frost will do this.

Tomatoes not setting.—I notice in your issue of 15th ult. remarks by J. Crook as to Tomatoes setting badly in the West of England. I agree with him to a certain extent that they have not done well this year, but am happy to say that in my garden I was able to gather ripe "open air grown" fruit for more than five weeks, but had nothing in way of crop to compare with the last three years, and am sorry to say that, as my Potatoes had disease, a number of the Tomatoes had also suffered. My Tomatoes are grown quite in the open, tied to iron stakes, and I find that plants quite in the open do better than those planted against a south wall, and such has been my experience, not only this year, but in previous seasons. They set a heavier crop and ripen earlier, and are less liable to attacks from the birds, which have developed an unhealthy taste for Tomatoes. At present I have a fair amount of fruit of good size ripening indoors. By these remarks I do not wish to imply that I have had a really good crop; in fact, it has only been about a seventh or eighth of what I have had in previous years, and I know in some gardens in this neighbourhood out of doors Tomatoes have been practically an utter failure, due no doubt to the very unfavorable weather we have had.

PLANTS AND FLOWERS.

OUTDOOR PLANTS.

CACTUS DAHLIAS.

Numerous new Cactus Dahlias are being sent out every year, and at the autumn shows their cut blooms are an important feature. The present fashion in Cactus Dahlias, which is much to be regretted on the score of garden effect, has led to the ousting of the broader-petalled varieties by forms possessing narrow, tubular petals. Although it must be fully recognised that many of these flowers are individually very beautiful, the beauty of a single flower on a show-board is no proof that the plant which bore it has any value for garden decoration. Even if the present day Cactus Dahlias produced their flowers freely and carried well above the foliage on long stems, which a large proportion of them do not, the narrow-petalled blossoms cannot collectively create the same striking effect as those with wider petals. What the owner of a garden requires is not plants that will bear a few blooms to win prizes at shows, but that will afford an ornamental feature when growing in the garden, and nothing is to be learnt on this point from visits to the largest and best shows. Even at nurseries it is often impossible to ascertain the natural habit of varieties, as these are frequently grown for the production of exhibition blooms and treated with that object solely in view, being thinned in order that they may bear a few perfect flowers. A sparse scattering of the best of blooms is useless for purposes of display, what is wanted being plants that will give grand breadths of bright colour in the early autumn. The type of Dahlia that is required to produce a brilliant show in the borders is well represented by *Glare of the Garden*, a comparatively old variety, classed among the decorative section in the few lists still retaining its name. This amply justified its title, being, when in full bloom, a blaze of vivid scarlet, but its flowers undoubtedly lacked much of the refinement of the premier show blossoms of to-day. These latter are unsurpassed for indoor arrangement, but this and garden effect are two very different things, and the plant that is excellent for providing flowers for the house may be useless for furnishing the borders. If some hybridiser, taking *Glare of the Garden* as his pattern, were to raise a race of Dahlias as free-flowering and having the same excellent habit in many bright colours, the autumn garden would gain largely in attractiveness.

Cactus Dahlias should not be planted in heavily-manured soil, as this encourages growth at the expense of flowers, a fatal fault, as profuseness of bloom is the chief desideratum. Plants to be of use in the garden should carry their flowers on tall stems well above the foliage, but in many varieties that bear exhibition blooms these are half-hidden by the leaves. These two features—namely, the abundance and good carriage of the flowers—are the chief requisites of the Cactus Dahlia from a decorative point of view. The same varieties do not invariably behave identically in different soils, so that what is recommended by one grower may not realise expectations in another locality, but judging one district with another, the following kinds appear fairly reliable: *Ajax*, orange, suffused with salmon-luff; *Bessie Mitchell*, bright orange-yellow, blended with red, pink, and salmon; *Britannia*, apricot-salmon; *Columbia*, crimson, with petals tipped white; *Florodora*, deep crimson; *Florence*, yellowish-orange, very good; *Gabriel*, red, with white tips, petals much incurved, free flowerer; *Gloriosa*, bright crimson, old, but one of the most showy; *Goldfinch*, yellow; *J. Weir Fifo*, blackish-purple, striped magenta; *J. W. Wilkinson*, rosy-crimson; *Lord Roberts*, the best white; *Lottie Dean*, yellow, shading to buff; *Lucius*, deep orange; *Lyric*, yellow, with scarlet tips to the petals; *Magnificent*, rosy-orange, shaded salmon; *Mary Service*, heliotrope-pink, shaded yellow; *Mayor Tup-penny*, deep yellow, outer petals orange-fawn edged with crimson; *Mrs. Carter Page*, velvety crimson, not a very free bloomer; *Mrs. Edward Mawley*, yellow, very good; *Mrs. J. J. Crowe*, yellow; *Mrs. Winstanley*, bright

orange-scarlet, good in every way; *P. W. Tulloch*, salmon-red, shaded maroon; *Richard Dean*, dark red, with petals tipped white; *Starfish*, brilliant orange-scarlet; *The Clown*, brick-red, upper half of petals white; *Uncle Tom*, crimson-black, good; *Vesta*, rosy-pink. S. W. F.

FLAG IRISES AND LUPINES.

THESE are common flowers, but it is to common flowers that gardens owe their chief charm, and in the early summer thousands upon thousands of Flag Irises and Lupines dower with their beauty all manner of gardens throughout the length and breadth of the British Isles, from the tiny cottage plot to the noble pleasure of the stately manor. Happily these plants, unlike such things as *Ostrya magnifica*, *Gerbera Jamesoni*, *Colechicum speciosum album*, and some of the newer sculling *Daffodils*, are within reach of the poorest pocket, and, also happily, they are of the easiest possible culture. Herbaceous Lupines when once planted spring up year after year, perfecting their long spikes of white or blue blossoms, and succeed in any soil, though attaining their noblest proportions in that which is deep and rich. The Tree-Lupine (see our illustration, p. 523) often reaches a height of 8 feet, with a like diameter, and being smothered with pale yellow flower-spikes; there are also white and pale blue forms of this plant. When they

Irises and Lupines. From a photograph sent by Miss Harrison, The Old House, Whitburn, Sunderland-on-Weir.

reach a large size they often die, but plants are easily raised from seed, and if a few seedlings are kept in the reserve garden, the dead plant is easily replaced. Flag or, as they are more commonly called, German Irises appear indifferent to soil and site, and may be seen blooming equally well on a steep railway embankment, baked by the sun to an almost brick-like hardness, and in the deep, moist soil beneath a standard Apple-tree in a cottage garden. The commonest form is the purple-blue, but there are numbers of charming named varieties, many of which are as beautiful as the Orchids of the hothouse. Of these the following is a good selection: *Princess of Wales*, the best white; *flavescens*, pale yellow; *aura*, deep yellow, this variety must not be confounded with the tall-growing species of the same name; *atro-purpurea*, deepest violet; *florentina*, pearl-grey; *pallida* and *pallida dalmatica*, different shades of lavender, sweetly scented; *Mme. Chereau*, white, fringed with blue; *Bridesmaid*, white and lavender; *Victorine*, white and violet; *Apollo*, yellow and crimson; *Queen of the May*, rosy-lilac; *Arnold*, purple and fawn; *Darius*, yellow and chocolate; and *Celeste*, pale blue. Flag Irises occasionally suffer from rotting of the tubers. When this occurs the rotten part should be scraped away and the part dusted with powdered charcoal, after which granite sand should be placed over the cul tuber.

S. W. F.

FLOWERS ALL THE YEAR.

"In the Royal ordering of gardens there ought to be gardens for all the months of the year," so says Lord Bacon, yet it is but seldom done, though where "grounds" are fairly extensive it is comparatively easy. For gardening purposes winter begins in November. For many reasons the

WINTER GARDEN is better away from the "dressed" grounds, and in my garden at Oaklands it is in the open kitchen garden. Near the bottom of my garden is a row of pyramidal Pear-trees, making a good screen to the Violet-bed beyond them. A fair large lawn slopes gently to a row of old Nut trees, under whose wide-spreading branches are planted several thousand *Galanthus Elwesii*. The lower branches of the Nut-trees touch the ground in the summer, so as to completely shade the Snowdrops, yet when the leaves are shed the branches rise up several feet and thus protect the dainty flowers from most of the rain, frost, and snow, yet permitting them to enjoy all the winter sunshine, for they face south. A thick hedge of Mahonia forms the fourth side of this winter garden. There is a border at its feet for autumn Cyclamen; these continue flowering till after Christmas. At the foot of a Yew hedge the winter-flowering Jasmine is planted, with double Primrose, red, lavender, yellow, and white, between them and the path. Several Witch Hazels are on the

lawn, with *Chionodoxa* planted about them, and quantities of Autumn and Winter Crocuses, Snowflakes, and winter Aconites in the grass. For the three winter months there will be no lack of flowers, for the autumn Violets will be in bloom in November. A large "patch" of Christmas Roses should be at one end of the Violet bed. The catkins of the Hazels, the bronze leaves of the Mahonias, and the long sprays of the Jasmine and the Witch Hazel, with Violets and Christmas Roses, will make a lovely winter bouquet. In my

SPRING GARDEN, warm, dry, and sheltered by a Laurel hedge, all the half-hardy trees and shrubs are planted in groups or as specimens on the Grass. A border, 120 feet by 8 feet, follows the line of the hedge, with a path between. Such shrubs as *Carpenteria*, *Abelias*, *Buddleias*, are planted in the border, every spare inch being filled with bulbs, Yuccas, and *Kniphofias* (Torch Lilies). The newer *Daffodils*, particularly the white trumpet ones, *Tulipa retroflexa*, *perica*, *Ostrowskyana*, *Kolpaknyskyana*, *vindifera*, *Greigi*, and many others, all kinds of "Vernal" Crocus, spring-blooming *Sternbergias*, *Fritillarias*, all the early-flowering bulbous Irises, also *I. stylosa*, *I. pumila*, and *I. p. hybrida*, *Hya-cinthus*, not only the better-known Dutch, but the beautiful species, *Muscarias*, dwarf *Scillas*, and *Scilla nutans*, are only a few of the bulb-growth. Sheets of *Anemone hepatica* and *A. blanda*, with *Forget-me-nots*, *Alyssum*, and

great beds of Wallflowers in every colour, keep this garden beautiful for the three spring months. Amongst the young trees and shrubs planted here are Paulownia, Judas-trees, Melia Adirach, double-flowering Peaches, Cherries, Almonds, Apples, Heath, Lilacs, Tree-Paeonies, and a large group of Clematis fragrans, all early spring bloomers. When May comes, this garden is not so desolate, for the bulbs go quietly to rest, Mexican and Californian bulbs taking their place, the shrubs giving a well-furnished look. No summer flowers are planted, it being too hot for them, except in one large bed (where Wallflowers grew during the winter). This has standard Plumbagos, with a carpet of pink Ivy-leaved Geraniums.

The woods come down to the house on the south side, and here, in the cool, is the glory of these old gardens, the Rhododendrons—hundreds of them, from the young bushes planted last autumn to the 20 feet high trees of R. arboreum. In the most sheltered spot are the Sikkim Rhododendrons, and near in an open space is the little rock garden. All kinds of Primroses, Primulas of many kinds, Auriculas, the tiny Daffodils, Fritillarias, late Snowdrops, Snowflakes, Hepaticas, also H. angulosa, many varieties of Anemones, Trilliums, Blood Root, spring Cyclamens, Dog's-tooth Violets, Aubrietias, double Arabis, double Meadow Saxifraga, need a cooler soil and more shade than the "spring" garden can give. The glorious Poppy Anemones want a different soil and site, so they find a home in the "Iris garden." A wide path leads to it, bordered by groups of spring-flowering shrubs. Peaches, Almonds, Plums, double Sloes, Apples, Cherries, Magnolias, flowering Currants, Forsythias, and Berberis are a few of them, with Rose-bushes between. On either side lie orchards of Almonds, Apples, Plums, and Cherries, with double Gorse and yellow Broom between, with single Roses, like the hybrid Sweet Briars, climbing amongst their branches. The fruit-trees are standards.

Sauntering back, one sees for the first time the seas of Daffodils in the woods. Each family is planted separately in drifts—here Star Daffodils, there bicolor and white "Trumpets." A fairly large planting of N. cernuus, albicans, W. Goldring, moschatas, and other white ones is doing well. May brings almost too much. All the later Daffodils and the later Rhododendrons are in their splendour, but the special gardens of the month are the Tulip field and Iris garden. Past the rock garden, where the Auriculas are at their best, through the Daffodils, Azaleas, and Rhododendrons, a wood path leads up to the Tulips. Thousands of May Tulips, 2 feet to 3 feet high—Darwin, Cottage, Roses, Violet, Byblomeas, Bizarres, Rembrondt, and Parrot, with wide stretches of yellows. A border, 150 feet long, of single Paeonies, with German Irises behind them, fronts the Tulips. The woods creep close on three sides, the south-east face being Grass. It is a positive relief to the eyes to go to the soft blues, yellows, and whites of the Spanish Irises.

June is the month of Roses, which hold full sway in the Rose garden, the exception being Pinks, and May is their month. The pinks are planted on the edges of the beds. Towards the end of May is the carnival of Paeonies and different Flag Irises. These are in the Iris garden, and the late spring (or early summer) shrubs are coming out—Deutzias, Weigelas, Mock Oranges, etc. A bed of some 500 Paeonies, double and single, is beautiful. In the middle are the Spanish Irises, the many leaf wide belt of German Iris swaying down one side—pink, yellow, blue, purple, white, hundreds of different shades and tones. The English Irises are pushing up their flat buds, and in the lateral bottom of a pond the Japanese ones are appearing. Close to the house is a wide path covered by a pergola of Roses, Clematises, Honeysuckles, and Vines. This forms the face and entrance to the Lily garden, the N.W. side being one of the walls of the garden, the end of the house being S.W., a shrubbery and paling keeping out the N.E. wind. Two-thirds of this garden is turf, with a narrow border under the walls and along the pergola. "Lilies everywhere," and nothing else but a few shrubs and trees, chosen for their beautiful autumn tints, prevail, for this is more an autumn than a summer garden. Apple-p-

sis on the walls, Azalea mollis, Berberis Thunbergi, Rosa rugosa (white type), and Japanese Maples for shrubs, with Sugar Maples, Medlars, and scarlet Oaks for trees. A long, wide belt of L. canaliculatum, with L. longiflorum in front, fits the bowler by the pergola. Tiger Lilies, L. croceum and L. pomponium, with L. elegans, L. Batemanii, and L. Wallacei in front, fill the border under the wall between the Maples planted here. In the groups of shrubs are Liliun speciosum, L. Browni, L. japonicum, L. Krameri, L. testaceum, L. sulphureum, L. auratum micro-vittatum, and L. n. Wittei. The cultivated part of this garden is planted with Bamboos and Chrysanthemums, with quantities of L. auratum in groups. On the edge facing south are the various Turk's Cap Lilies in groups, with L. Alexandria in front, L. rubellum being in the shady border under the house wall. The Lily garden will be in perfection during the latter part of July till

by forming special gardens for each season. This "royal ordering of gardens" in no way interferes with the formal bedding out or the herbaceous borders, though, space and position permitting, there should be two long, wide borders leading from one part of the grounds to another, backed by shrubs, in a sheltered, shady spot. One is for Delphiniums, the other Phloxes, with Gladioli (but not G. Brecheyleucis, the scarlet of whose flowers runs the tints of the Phlox) and Hyacinthus candicans.

Oaklands, Davlish.

A. BAVLSON.

GROWING AURICULAS IN POTS.

I wish, be much obliged if you will kindly give me some hints on growing Auriculas. I have some good varieties, and succeed in growing healthy plants, but do not get the trusses of bloom I ought. The individual blooms are fine, but there are never more than three or four at most on one stem. I feel convinced I make some mistake, but cannot determine what it is. At first I thought I over-potted them, so this June I put them into decidedly smaller pots, and they are in a good compost of loam and old stable-manure, and for the time of year look wonderfully healthy. Perhaps I ought only to allow one stem on each plant, pinching off the others as they grow? So far I have always allowed two or three. I understood that alpinas should be able to carry two good trusses on each plant, but the same latitude applies to both kinds, and I grow both. I have seen the plants nearly hidden by the fine trusses of bloom, and I wish to produce the same, and as I succeed in having very healthy plants, I think I must make some cultural mistake, and will be most grateful for any advice on the subject. Auriculas are my special hobby, and I am most anxious to produce some fine trusses of bloom this coming spring.—SKEWTON'S KNIGHT.

[High class named show Auriculas, such as self and edged flowers, to which we infer from your note you refer, grow rather slowly and do not always bloom, even where they have good leafage—indeed, it is possible by too high culture and feeling to create leafage of too coarse a kind, and not flower—producing crowns. These plants need as compost two thirds of good well-decayed old pasture or turfy loam, the other portion being composed of well-fermented cow-manure, or old hotbed-manure, though roughly rotted leaf-soil and sharp white sand. These ingredients should be well mixed and even a little scot may be added. The best time for potting is in the spring, just

Yellow Tree-Lupine in the herbaceous border. From a photograph sent by Rev. G. S. Whitehead, Bedale, Yorks. (See page 522.)

the end of September, but only L. speciosum will be still in bloom then. Before this, however, the Asters will be in full flower. All the Asters are late-flowering ones and mostly tall; they are carefully trained like specimen Chrysanthemums, all surplus shoots being thinned out. A belt of Heleniums, flowering at the same time, gives the high note of colour. By the middle of October the Chrysanthemums are in bloom, and very pleasant it is to saunter in this warm, sheltered spot during the mild October days, admiring the richly coloured flowers, set off by the Bamboos and the glowing colours of the Ampelopsis, for here, on the sun-warmed "cob," the leaves hang long. The Chrysanthemums are trained fan-shaped, like the Fuchsias in cottage windows, and being set at every angle, the flowers are well shown.

I have tried to show how flowers may be had in perfection all the year, not by attempting to grow every kind in one aspect and soil, but

after the bloom is over, as it is then new roots are made. In doing that it may be needless sometimes to shake out all the old soil, to cut away a portion of the root-stem that may have become useless, and thus to encourage the production of new roots, which are thrown out just beneath the leaves. When the plants are so treated it is well to get them first into rather small pots—such as are known as large 60's, or about 3 1/2 inches across the top. If the plants be very strong, it may be needful to put them into 8-inch pots. In all cases never overpot, rather underpot, as Auriculas are not strong rooters. Perhaps your plants have been in rather too large pots, they may not be in good firm soil, or they may be at times over-watered.

During the winter, when they rest, the soil in the pots needs to be but just kept moist. Original sources say that now in rather smaller pots the plants look wonderfully well,

we see no reason why, if you give them a shift into others a size larger in March, they should not flower well in April. None of the fine show or alpine varieties bloom too freely. As exhibited, the former seldom carry but one stem and truss of flowers—perhaps from five to seven pips. Alpines commonly carry two or even three trusses of from five to nine pips. None of the finest show varieties are strong growers in the sense that border Auriculas are. We

nailed in as far as it has become well ripened, beyond which it may be cut away, filling in all the vacant spaces with that which is left. *Villo de Lyon* and *Viticella rubra* belong to the *Viticella* section, and flower on the young or summer shoots. The aim, therefore, should be to encourage young, vigorous shoots by cutting down the summer growth each season, as soon as the frosts have disfigured the plants, to within 6 inches of the soil. You should then

and passed through a 1-inch sieve to relieve it of sticks and stones, etc. A 2-inch layer of this should be spread evenly over the surface as soon as the beds have been cleaned.—A. W.

Senecio pulcher.—No herbaceous border is complete without this handsome and rather late-flowering Groundsel. Its large, rich, purplish-crimson flowers, with golden-coloured discs, are most attractive. It is quite hardy, and will succeed in any ordinary garden soil, but on account of its late flowering it should be accorded a sunny, open position, as shade renders the flowering period unduly late. It attains a height of 2 feet, and is, therefore, useful for planting near the front of the border.

Aster acris.—This is one of the most useful of the Starworts, and several clumps should be grown in borders where early flowers are in request for cutting in early autumn. It blooms very early in September, and its colour, a purple-lilac, is not found very much in gardens at that time of the year. The hardiness of Starworts is well known, therefore there need be no diffidence on the part of anyone wishing to procure plants and shifting them now, provided, of course, that the ground is not absolutely frost bound. A little rotted manure dug in when planted will ensure good strong specimens by next flowering season.—LEAHURST.

Planting Spanish Irises with other bulbs.—Many people are now beginning to wake up to the fact that a few shillings expended in the purchase of Spanish Irises is a good investment if one desires to have beautiful blossoms for cutting in June, and as now is the time to plant, may I point out that other bulbs planted with them will not hinder them. One may for example, plant alternately in the bed *Narcissi* or *Scillas*, which bloom and finish long before the Irises are ready. Some may argue that Irises are soon over—that may be so, but they are extremely beautiful whilst they last; but if planted with other bulbs as suggested, the arrangement will be found to answer. For the rest of the summer *Mignonette* may be sown in April.—LEAHURST.

INULAS.

If you can refer me to an article published in *GARDENING ILLUSTRATED* on *Inulas* I shall be much obliged, as I have looked through this year's and the two previous years of your paper, and fail to find any mention, except in a casual way if not dealt with by you for some time I should be glad to do so through the medium of *GARDENING ILLUSTRATED*, you could give an article on the plant in question.—INUL.

[Perennial Composites, few of which are important for the garden. 1. *Helenium* (*Elecampane*), a vigorous British plant, 3 feet or 4 feet high, with a stout stem, large leaves

The Blood-Root (*Sanguinaria canadensis*).

have seen myriads of Auriculas of the show forms in pots, but have never seen the plants nearly hidden by flower. Commoner varieties of three or four-year-old plants in 6-inch or 7-inch pots may produce six or seven trusses, but not the best show or alpine varieties. The plants should be wintered in a cold-frame, over which a mat or two should be thrown in hard weather. Keep the plants on stages and rather near the glass. Frost does the plants no harm, but does disturb the roots, sometimes breaking the pots. Failing a cold-frame, then winter on the top-shelf of a cool greenhouse. At all times give plenty of air.]

SANGUINARIA CANADENSIS (BLOOD ROOT).

A DISTINCT N. American plant with thick underground stems from which spring large greyish leaves, cut into wavy or toothed lobes, and full of an orange-red and acrid juice. The stems, from 4 inches to 8 inches high, each bear a solitary and handsome white flower in March. It grows best in moist places and in rich soil, but, like many other plants, it has a dislike to certain soils, and is not always easy to establish, the most likely places being peaty or leafy hollows.

NOTES AND REPLIES.

Weeds in lawn.—How can I rid a croquet lawn of Plantains? Two winters ago I had all the roots taken up by a boy with a knife, and last summer they came up as plentifully as ever. The lawn has been dressed with salt, but with no good effect. Does anyone recommend a weed-killer, and, if so, which is the best way to use it so as not to kill or injure the lawn?—DAVIDES.

[The boy when he cut out the Plantains did not go deep enough. The plants should always be cut off quite below the collar, taking the lawn in 6-foot widths, marked out by a line on either side, so as to be quite sure that all the ground is carefully dealt with. After the lawn has been carefully gone over, it should be top-dressed with some good loamy soil, rotten manure, and wood-ashes, to encourage the Grass to spread and fill up the holes left by the clearing out of the Plantains.]

Pruning Clematises.—Would you kindly tell me when and how the following Clematises should be pruned? *Duchess of Edinburgh*, *Fa ry Queen*, *Mme. Baronne Vielard*, *La France*, *Beauty of Worcester*, *Ville de Lyon*, *Viticella rubra*, *lanuginosa candida*. All are growing outdoors.—J. L. M., *Rhyl*.

[The varieties *Fairy Queen*, *La France*, *Beauty of Worcester*, and *lanuginosa candida* belong to the *lanuginosa* section, and should be pruned in February or March, removing only the weak, straggling, and overgrown branches. The strong one-year-old wood should be

mulch the surface with some good rotten manure, watering freely, when dry in the spring, with an occasional dose of liquid-manure. *Duchess of Edinburgh* belongs to the *florida* section, and must be treated in the same way as the *lanuginosa* forms.]

Clearing beds and borders.—When we get into November it is found that in every garden there is a deal of clearing up to be done; especially in this so where summer subjects have been mainly planted. The sooner the beds and borders are cleared and the soil turned over to sweeten the better. In herbaceous borders, also, cutting away of dead stalks to let the light in about the surface, and forking over, and perhaps mulching with manure, will assist the plants. Owing to so much moisture this season grubs are very prevalent, and one way of dislodging them is by removing some of this now unnecessary growth.—WOODHASTWICK.

Top-dressing Lily of the Valley.—Now that a general clearing up of herbaceous

borders is taking place, a little attention should be given to beds of *Lily of the Valley*. As a rule, *Lily of the Valley* receives but scant attention, and beyond relieving the plants of dead foliage and the soil of weeds—and this in many instances is deferred till spring—they are left year after year until the crowns and part of the root-stock become elevated above ground level. This is quite wrong, for if a bed of these Lilies which has been naturalised in a wood for some years is examined, it will be found that the crowns are nearly, if not quite, covered by the accumulation of leaf-mould resulting from the decaying of the leaves which fall from the trees. These form a winter covering in the first instance, and when they decay the soil becomes enriched, to the benefit of the roots, which form a network in all directions just under the surface. In a garden, more often than not, the surface soil becomes gradually lessened by the weeding and cleaning, and nothing is returned to make good the loss, hence the necessity and wisdom of making this top-dressing an annual affair. There is nothing better for the purpose than decayed old holed material, well chopped up,

Ieula glandulosa.

and yellow flowers, is well suited for planting with other large-leaved plants, or as an isolated specimen on rough slopes or wild places, in good soil. 1. *Oculus Christi* grows 1½ feet to 2 feet high, and bears orange flowers in summer. 1. *salicina*, *montana*, and *glandulosa* are similar, the last being the finest. Easily propagated by division or seed.]

INDOOR PLANTS.

PELARGONIUM GUSTAVE GIRARDIN.

This is the best of a set sent to me by Francois Gerbeaux, of Nancy, and is a fine distinct bicolor with large, well-filled trusses and very brightly coloured flowers.

W. E. GUMBLETON.

PLANT FORCING BY ETHER.

We have on several occasions drawn attention to the remarkable discovery of forcing plants by ether, made by M. Johannsen, and to the interesting experiments which have been made by various persons in the same direction. It is now no longer a question of experiment, but one of application rather. The experiments made by M. Frederic Harms, one of the best known forcers in Hamburg, who owns several acres of ground under glass, are of the highest practical importance, as they were undertaken with the object of testing the results of the first experiments. For the purpose of observation, the bushes are enclosed in a hermetically closed box. Pure sulphuric ether is used, not alcoholised ether, which is more expensive, or ether of petrol. The ether is injected into a wide receptacle, which is open to allow of evaporation, and hangs inside the box by means of a funnel inserted in an opening in the top of the apparatus. The ether fumes being heavier than the air find their way downwards, and would penetrate even the soil surrounding the roots of the plants if not prevented by the soil being kept very dry and covered with sand. The amount of ether administered varies with the season and the kind of plant. By inserting small plants between the larger ones, M. Harms was able to find room for seventy plant at a time. The bushes remained generally forty-eight hours in ether vapour, but in the case of plants less susceptible to the action of ether a longer time was allowed. The temperature within the receptacle had also to be considered, seeing that at 23 degs. Fahr. for the first twenty-four hours the ether has no effect and at 85 degs. Fahr. the plants are overwhelmed. The ether needs for its effective action a temperature of 60 degs. to 65 degs. Fahr., allowing a fall of temperature to 50 degs. in the night time.

As ether vapour is very inflammable, care should be taken not to approach it with any flame that is not hermetically enclosed. After being etherised, the plants are transferred from the receptacle to a greenhouse warmed to a temperature of 62 degs. to 68 degs. Fahr., as for ordinary forcing. In three or four days the flower buds open, eight days later the clusters are fully developed, and six days afterwards the flowers are fully open. Plants so etherised present a handsome appearance, and the sickly look which is sometimes seen on forced plants is absent. On the contrary, the flower-heads are abundant and strong, and the foliage of a healthy green, which is not the case with non-etherised plants. The use of an apparatus of small size is applicable to small Lilacs forced in pots, as is the custom in Germany. For the tall plants a special receptacle has to be built in brick and cement. It is found that the adoption of this process means a great saving of labour, material, and time. The French florists have had reason this year to regret their neglect of the discovery, when, owing to the abnormal summer, the Lilacs destined for forcing, although grown in the open air in order to prolong their rest, have continued more or less in growth owing to the continuous rains.

In most cases the buds are badly formed and incompletely developed, the flower thyrses make a poor show, and the clusters will be short. The ether-forcing system being independent of had seasons makes such results impossible, and Lilacs which are unfit for forcing can be got to flower well.

ALBERT MAUDSLAY

NOTES AND REPLIES.

Heating a greenhouse.—I am thinking of utilising some hot water from the works for heating a greenhouse. My idea was to conduct the water backwards and forwards under the floor in pretty deep brick channels, so that a large quantity of water would always be under it, which would retain a heat from the time the works close on Saturday till Monday morning. The question is, would a temperature of 100 degs. to 110 degs. in the water be sufficient to give satisfactory results? Could any of your readers give me any information on this subject?—H. BROWN.

[We fear such a plan would be of little use, as we fail to see how the circulation could be carried on. Besides, if the weather should happen to be very severe the water would get too cold. It would be far better to heat your house in the ordinary way with a boiler and hot-water pipes.]

Boronia megastigma.—I have had some seeds of the following sent me from Australia: *Boronia megastigma*, *Clanthus Dampieri*, *Telopea speciosissima*. Would be much obliged for any instructions you may give me in your valuable paper, which I take in regularly. Their present and after treatment I would like to know at your leisure?—W. C. T. STOKLEN.

[In the case of seeds just received from Australia, your better way will be to keep them until next March before sowing, as the tiny seedlings would in the depth of winter have a hard struggle to survive. *Boronia megastigma* grows best in sandy pent, which, owing to the

delicate roots, otherwise they will perish. A space of about three-quarters of an inch should be allowed between the little plants, which, as soon as they have taken hold of the new soil, should have their tops pinched out, in order to encourage a bushy habit of growth. The next shift will be singly into small pots, and after they are established therein the young plants may be given ordinary greenhouse treatment. The flowers of this *Boronia* are small, dull-coloured, but deliciously fragrant, which latter feature causes it to be an universal favourite. It blooms during the spring months. You will find directions as to raising the other two under the headings "*Clanthus Dampieri*," and "*Telopea*," p. 533.]

Bulbs in pots.—Many amateurs fail to get their bulbs to start freely into growth. In the majority of cases of failure that I have investigated, the cause has been too much kindness. The too careful cultivator pots or boxes his bulbs in rather dry soil and stores them under cover where the heavy autumnal rains cannot get at them, and, in many cases, puts them at once into the glass-houses or frames where the temperature is too high for them before they are well rooted, with the

New French bicolor Pelargonium Gustave Girardin.

minute character of the seed, should be passed through a sieve with 1/4-inch mesh. A 5-inch pot is very suitable for sowing the seed in, and it should be quite clean and half filled with broken crocks, over which place a layer of the rougher portions of the peat, and, finally, the prepared part, which must be pressed down firmly and made quite smooth. Then water through a fine rose, and while the surface is still wet sprinkle the seed thinly thereon. Slightly cover with a little fine, very sandy peat, and place a square of glass over the pot. This glass must be allowed for in filling the pot with soil, which should be kept about 1/2 inch below the rim. A shady part of an intermediate-house, or the warmest portion of the greenhouse, is the best place for the seed, which, carefully attended to in the matter of watering, should germinate in a month or six weeks, according to its age. Directly the tiny seedlings make their appearance the glass must be removed, and the young plants inured to the ordinary atmosphere of the structure in which they are growing. When about 1/2 inch high they will need pricking off into other pots, which should be prepared exactly as for sowing. The soil must be made firm, and great care should be taken that it is thoroughly closed around

result that they start weakly into growth, or fail to start at all. If they were set out-of-doors and covered with ashes, Cocoa-fibro, or dry leaves until they fairly started into actual leaf growth, and when the roots could be seen pushing through the pots, there would be very few failures. I find at the present time in the open air without any protection at all, the Roman Hyacinths, Narcissi, Tulips, etc., are pushing up as if spring had already arrived, and where some of them had an excessive lot of rain water, they were the healthiest and most advanced of all.—J. G., Gosport.

Isolepis gracilis.—This is one of the most valuable of green edging plants for conservatory or greenhouse stages in the winter, as it delights in cool, moist places, and must not on any account be allowed to get dry for any length of time, or its graceful dark-green pendulous leaves assume a yellow tint. For decoration it is most useful in rather small pots of from 3 inches to 5 inches in diameter, and a good stock may soon be obtained either from seed, or by dividing old plants. A cool, shaded place, with light, rich soil, and an abundance of water at the root, are all that is needed to grow perfect masses of this pretty plant.—G., Gosport.

CHRYSANTHEMUMS.

PREPARING FOR NEXT SEASON.

No sooner are the flowers faded than a start has to be made to prepare the plants for next year's supply of bloom. To grow Chrysanthemums really well a long season of growth is absolutely necessary. By obtaining satisfactory cuttings a good foundation is laid. Some varieties are shy in producing any cuttings; some discretion then is necessary in such cases in cutting down the old flower-stems. In the case of shy producers of cuttings do not cut the stem down lower than to within 2 feet of the soil. Although the most desirable cuttings are those that push through the soil some distance from the stem, stem cuttings are better than none at all. In some cases where these stubborn varieties fail to throw up cuttings direct from the base, they often give cuttings from the stems after the plant is cut down to the height named. The objection to stem cuttings is that they are liable to form flower-buds instead of growth after they are rooted. Many varieties give cuttings in abundance direct from the base without the slightest trace of premature budding. Such as these then should be cut down to within an inch or so of the soil. It very often happens that these free-growing kinds have far too many growths springing up from the base to afford a sufficiency of space for each to develop properly. Where such is the case it is much the best plan to thin out these weakly growths and give more room to others, so that when the time arrives for taking the cuttings they will be sturdy and strong instead of being weak and attenuated in growth. Directly the plants are cut down the old stools should have a position assigned them where they will be close to the glass in a cool-house or frame, simply protected from frost and lamp. No place answers better than a vinery or Peach-house at rest, as here the Chrysanthemums obtain abundance of light and air, which induces a stocky growth.

Care is necessary in supplying the old stools with water; too much is injurious, creating a paleness in the young leaves, which is objectionable. When the leaves are rendered so pale in colour, a long period often elapses before they regain their wonted vigour and colour. It is surprising how little water is needed to induce growth to be made from the base after the plants are cut down. Where the roots are washed bare on the surface they should be covered with a portion of sandy compost, adding to it decayed leaf-mould, this having a decided tendency to encourage from the base growth that is firm and in every way desirable. In stubborn cases, where growth positively refuses to move at the base, it is necessary sometimes to rectify the drainage if this has got out of order, and even to plunge the pots in a gentle bottom heat and syringe the stems several times daily before a start into growth will be perceptible. The slightest sign of greenness should be dealt with at once by fumigating the house with Tobacco smoke or by dusting the plants individually with Tobacco-powder and syringing them afterwards to cleanse the leaves of both powder and fly. Air upon all favourable occasions will induce a stocky growth.

It is desirable to take a cutting at any time, provided it is a good one, and from a shy grower. Personally, I am not in favour of early propagation, as it is neither desirable nor necessary. There are many varieties (exhibition) that require early propagation to ensure bud formation at the proper time, but when the object is the decoration of the home or conservatory, the beginning of the year is soon enough. Then good, strong cuttings which will root readily and make sturdy, strong plants in a short time are abundant, and if an experiment has been tried with a few put in in November or December, the January struck cuttings will be as far advanced, and in many instances ahead of the others put in early. I would warn amateurs not to let their enthusiasm carry them too far while at the November exhibitions. They perhaps see a grand bloom, and conclude that they must have the variety in their collection, but after they do get a plant, and grow it on, they are disappointed. I think this large bloom system of growing Chrysanthemums is a pity, not

ing the future of this glorious flower. The system of inserting three cuttings round the sides of a 2½-inch or 3-inch pot is a splendid one for those who grow mainly for cut-bloom and decoration. These can be grown on as one plant. The labour is almost nil, and damage to the tiny roots is reduced to a minimum. A nice fibrous compost, with a good dash of river sand, forms admirable rooting material. When the cuttings are inserted, stand the pots on a stage near the glass, preferably on a bed of ashes. Use no close frame, which encourages damping, but shade with newspapers from sun until rooted. A slight sprinkling is all the cuttings will require until growing nicely, when they may be shifted on in the usual way. D. G. McL.

Bridge-of-Weir, N.B.

CHRYSANTHEMUMS AT THE AQUARIUM.

I WAS delighted to find Herbert Millington (p. 503) entering a protest against what I always consider the insane craze for monster blooms, and delighted to find you publish such a protest. To me as a keen lover of flowers it is saddening to see a collection of mops on so many poles.—F. ALEXANDER.

I quite agree with the remarks of Herbert Millington (p. 503) in reference to the exhibition of Chrysanthemums at the Aquarium. It seems a great pity that mere size should seem to be the predominating feature of show blooms. Is there no beauty in any of our varieties—some of which are old—and which were once seen at exhibitions, but now, owing to their being ousted by larger, and, in some instances, coarser-built blooms, are classed as "decorative" sorts? Surely there is room for classes of this latter group, many of them being yet grown by persons who prefer moderate-sized flowers in quantity rather than a few huge heads, which are really of little service apart from the exhibition-table. I am quite certain that this fever for new sorts every year, possessing greater size than others, is doing much to make people belittle the good qualities of other worthy varieties that cannot possibly come up to the mop-like heads. No wonder that some who once grew for show have given up doing so, because of the rage for new sorts of this character. "Let those grow for size who like, give me a score of decent blossoms to a plant," said a late exhibitor; "you get more satisfaction out of them." And I agree with him.—TOWNSMAN.

Under the heading of "Chrysanthemums," in the issue of Nov. 22 (p. 503) is a bitter onslaught upon the recent great show held at the Aquarium. This exhibition was voted by leading authorities as reflecting not a little credit on the skill of the various exhibitors. Mr. Herbert Millington, however, would have us believe it was quite otherwise—"bloated blooms . . . in round-bellied nudity" is his own description. But when he further says, "even the single Chrysanthemums are being ruined by this insane passion for size," he displays ignorance of the now recognised section of large-flowered singles. His remark as "to the hideousness of their environment" is mere platitude.—H. J. GILLINGHAM.

CHANGES IN THE METHODS OF EXHIBITING LARGE BLOOMS.

THE methods of exhibiting large blooms in vases initiated a few years ago by the N.C.S. is now adopted largely throughout the country. Scarcely an exhibition could be named where a class for large blooms staged in vases is not now found. Both the incurved and the Japanese types of the flower are now exhibited in this way. The great vase classes at the Aquarium for both incurved and Japanese flowers stipulate that five blooms are to be shown in each vase, and the blooms are to be so arranged that they face all round, in this way illustrating the decorative value of large blooms. At some of the provincial shows this season three large Japanese blooms have been staged in each vase, and appear to be quite enough in a vase of medium size. On the other hand, the smaller globular flowers of the incurved Chrysanthemum have been shown four in a vase. Arranged in this way, without any of the pomp and

always observed with blooms shown on boards, they look more interesting and less formal than usual. There is still room for improvement, however; each type of the flower may, with advantage, be treated similarly. The National Society has set an example in this direction, but even their methods might be improved upon. In the case of severely-disbudded Pompons, why could not these be shown at least a dozen in a vase? Six vases with a dozen blooms in each, and in distinct shades of colour, would make a most interesting exhibit. The large-flowered Anemones might also be exhibited in this way; half-a-dozen blooms in each vase, and three or six vases in each class, would represent these quaint flowers much better than by the system which now obtains. The singles, both large-flowered and small-flowered, might be treated in the same way as that suggested for the Pompons, and provided liberal prizes were forthcoming, competitors would be found, and the sameness which characterises the shows at the present time would not be seen. W. V. T.

NOTES AND REPLIES.

Single Chrysanthemum King of Siam.—This is a very fine dark crimson variety that I had seen last year, and it has proved quite a gem and a great acquisition in this particular colour. It is of dwarf, bushy habit, and succeeds well outdoors in an ordinary border, there growing to about the same height as *Mme. Marie Masse*.—A. W.

Chrysanthemum Crimson Source d'Or.—This is a terra-cotta crimson sport, but superior to the parent variety. At the time of writing I have in bloom in a cool greenhouse the parent plant, *Source d'Or* (old gold), *Lizzie Ailcock* (rich yellow sport), and the variety under notice, but none will compare for effect with *Crimson Source d'Or*. The vigour of this plant appears to be more pronounced than is the case with the other members of this family, and when the buds have been thinned they are very handsome.—E. G.

Freely-flowered Pompons.—A fine illustration of the value of the pretty little Pompons, when naturally grown and without disbudding, was recently seen at one of the leading northern Chrysanthemum shows. The stiff and formal disbudded Pompons will not compare with these freely-flowered plants when used for decoration. On the occasion referred to, six bunches of Pompons were asked for, and the grace and elegance of the numerous sprays contained in each exhibit showed how much is lost through not growing more of these plants. Many of the Pompons have been in commerce a long time, but as they are not often asked for at exhibitions, they have undoubtedly declined in favour. If the committees of the numerous societies throughout the country, instead of encouraging the large mops, as represented by the Japanese section, were to provide more classes in which the beauty and elegance of Chrysanthemums could be illustrated, exhibitions would prove more interesting than they are at present. Their decorative qualities are unequalled for the numerous small vases used throughout the house. For the larger vases they may be cut in long sprays, and in this way nothing formal or stiff can possibly be produced.—C. A. H.

Late Chrysanthemums.—Chrysanthemums are this season later than usual in forming their flower-buds, which for the late kinds is a distinct gain. This season, owing principally to lack of sunshine and the cool, showery weather, the plants kept growing, and now in November we have Dahlias in full bloom, and late Chrysanthemums only beginning to show their flower-buds, even in the south of England. After this date a sharp look-out must be kept. If it keeps mild, the longer the plants are in the open air the better, but with a decided change to frosty nights, they must at once be removed under cover. If grown in pots the work is soon done, but the majority that are grown for cut flowers are in the open ground, and must be lifted with good balls of soil and replanted in cold-house borders, where they will be kept as freely ventilated as possible, except when sharp frost is imminent. Happily the Chrysanthemum is amongst the best of all plants for transplanting when nearly in full bloom. If the roots are not broken much in lifting, and a good soaking of water

given to settle the soil around the roots again, the plants will not suffer if syringed for two or three days. Then they may be freely ventilated, and the atmosphere kept cool and dry.—JAMES GROOM, Gosport.

ROSES.

ROSE FRAU KARL DRUSCHKI.

HERR LAMBERT, of Trier, Germany, is to be congratulated on the production of this splendid Rose, a bud and fully-opened flower of

NOTES AND REPLIES.

One of the best Hybrid Teas.—Caroline Testout is one of the best of our Hybrid Teas, bright satiny rose in colour. It is nearly always in bloom from June to October, and this year far into November, for on November 24th I cut a superb bloom in the open, and what is of equal importance, it is a vigorous grower.—LEAMING.

Manuring Roses (A. J. W.).—If you do not object to the labour, the very best method of feeding Roses is to remove an inch or two of soil all around each plant, and spread out one ½ peck to 1 peck of solid manure, covering this over with part of the soil removed, using the surplus soil to mould up the base of

to Vines and fruit-trees. Bone-meal or fish guano is a good artificial manure to use in the spring, washing it well in if the weather is at all dry.

Roses on south wall.—I have just planted a new Rose bed with a south wall behind it about 5 feet high. I fancy I have made two mistakes, on which I should like your opinion. 1st, I have planted a Crimson Rambler and a Longworth Rambler against the wall, and I am now told they do not do at all against a south wall. 2nd, I have planted some Gloire Lyonnaise plants amongst the ordinary H.T. and H.P. dwarfs, and I am now told that the Gloire Lyonnaise should not be pruned at all, or very lightly, and I am afraid they will look very straggly amongst the other dwarfs. Would you move the

Bud and fully developed bloom of Rose Frau Karl Druschki. From a photograph by G. A. Champlin.

which we figure to-day. It is said to be a cross between Merveille de Lyon and Caroline Testout, and it is remarkable that the lower should be so pure white, as one would expect blooms from such a cross to have a shading of pink or blush. The only colour noticeable is in the outer petals of the buds, which are tinted rosy-pink, but the high-centred fully opened flower is pure white. The only fault it has is that it has no fragrance. Up to the present we have had no Hybrid Perpetual so pure in colour. It is free in growth and also blooms very freely.

the plants, if Tea Roses, to keep them protected from severe frosts. This method of applying the manure would prevent injury to the surface-roots in spring, which is always a danger to guard against when burying the surface dressing of manure. If you were to examine some plants so treated, say in May, you would find this manure all alive with tiny little rootlets, a proof that the plants appreciate the treatment, then when the time comes to give liquid manure the rootlets are present to to utilise it. It is the surface-feeding roots that do so much use to the Rose as they are

Ramblers at once and grow them up poles and wires, or would you leave them? In this smoky place we do not run much risk of smutstroke. If I move the Ramblers, could I take the Gloire Lyonnaise from their present places and put them up against the wall in the place of the Ramblers? I should prefer to leave them as they are if in the least advisable. I have seen Ramblers in this part of the world doing well against walls, but I am a perfect novice at anything connected with gardening, and if you could give me your advice I shall be obliged.—T. P. B.

[It is quite true that Crimson Rambler does not flourish against a south wall, unless the wall be low and a lattice work placed above upon which the growths of the Rose can ramble. It would be advisable to replant at

once, placing the plants either near an arch or against a pole to form a floral pillar. The latter is a capital way of displaying its beauty. Do not move the Longworth Rambler, as it is a fine Rose for south, east, or west wall. You have been somewhat misinformed about the Gloire Lyonnaise Rose. It will blossom even though pruned back to seven or eight eyes each season, but where wall space of moderate height is available this lovely variety is a most suitable one to plant thereon. As you will be removing the Crimson Rambler from the south wall, the Gloire Lyonnaise would take its place very well, and have a very suitable companion in Longworth Rambler. Many more grand varieties could be planted against low walls than is commonly done. Anna Ollivier, Marie Van Houtte, Mme. Lamhair, etc., we have had of considerable height, the growths, of course, being more thinned and the sturdy shoots suffered to remain as long as possible. You will probably need another Rose in the place of Gloire Lyonnaise. Try Mme. Pernet Ducher. We believe you will be charmed with it, for, although not a very double flower, it is lovely in bud and also when fully expanded.

Protecting half-standard Rose-trees.—I have just planted some half-standard Roses, a list of which I append. Will you kindly let me know whether it is necessary to protect the heads of all or some of them during the cold weather? I may add that, pending your reply, I have stuffed the Marie Van Houtte with straw and bound it inside with the same, tying the whole with wool. I have also a Reine Marie Henriette and W. A. Richardson, half-standard, planted in the spring. L'Idéal, Marie Van Houtte, La France, Gloire de Dijon, and Prince Camille de Rohan are what I have planted.—NEW SOUTH BRITAIN.

Of the seven kinds named only three need winter protection, viz., L'Idéal, Marie Van Houtte, and W. A. Richardson. Stiffening the heads with straw, or other non-conducting material, is a very good one, but we should advise you to remove it during mild intervals. A damp, stuffy condition causes more injury to the growths than a few degrees of frost. It is the zero frosts one should be prepared to combat as regards the Tea-scented and kindred tribes, and a stock of material should be kept near at hand to insert in the heads when such severe weather threatens. As we have repeatedly pointed out, lush-plants of these tribes may be effectually protected by a covering of earth some 6 inches deep around the base of the plants, and dry Fern or Bracken, straw, or evergreen hough-stuck in among the branches. Hardy Roses, such as Gloire de Dijon, Prince Camille de Rohan, and La France, require no protection.]

FERNS.

HARDY FERNS IN WINTER.

MANY of our most beautiful hardy Ferns suffer if exposed during the winter. When under cultivation it often occurs that they do not get the protection they find in their natural habitats. The leaves from deciduous trees provide both protection in winter and suitable material for the new roots to start into in spring. Grasses and other herbage also assist in protecting the crowns during the winter. Many who try to cultivate hardy Ferns forget that they are depriving them of the protection they find under natural conditions, and, consequently, do not succeed. Of course, it is not necessary to allow Grass and all kinds of weeds to grow up among the Ferns, yet something should be done in the autumn to make up for this deficiency. A good mulching of leaves may be recommended; either new leaves or those half-decayed may be used. The latter are best, as they provide more nourishment for the young roots in spring. If the plants are much exposed they should have a covering of dried Bracken or other light material. Bracken is about the best thing that can be used, as it will gradually decay, and by the time the Ferns start into growth the young fronds will be able to push through. Spring frosts are often destructive to hardy Ferns. Many of our British Ferns are worthy of cultivation under glass, more especially the beautiful varieties of the Lady Fern. The exquisite beauty of *Atyrium* (*Asplenium*) *Filix-foemina* plurimosum is not excelled, if equalled, in any of the exotic Ferns. When grown under glass care should be taken not to excite them into premature growth. Although a little heat will do no harm in the spring while they are making their

growth, giving them warmth during the autumn and early part of the winter will excite them and materially weaken them.

TREES AND SHRUBS.

PLANTS UNDER TREES.

IN THE lot of spare ground under Oaks and Scotch Firs, and sheltered from the north by a thick Laurel hedge, 15 feet high. Will you kindly tell me what flowering shrubs, flowers, and bulbs I can put in now to get a succession of bloom all the year round, as it faces the house and I want it to look bright? The space to be planted is 35 yards long and 8 feet wide.—LIONS.

[We take it the piece of ground is within the shade of the Oaks and Scotch Firs, and not that the trees are directly overhead. If so, there are many things suitable. If, on the other hand, the Oaks and Firs constitute in sort of plantation, the case is different. We assume the former, however, by reason of the hedge of Laurels. In such case, you may select of flowering shrubs any of the Weigelas, Lilacs, Forsythia suspensa, Rosa rugosa, and its varieties, *Pyrus japonica*, *Magnolia conspicua*, *M. Soulangeana*, *Ribes* in variety, *Genista prostrata*, *Spartium junceum*, and *Pyrus Malus floribunda*, of which several examples may be planted by reason of their great beauty in the early spring. A plant or two of the Scarlet Thorn, and the pretty, though short-lived, flowering Bird Cherry (*Prunus Pains*), together with *Berberis*, *Althaea*, *Acer Negundo variegatum*, *Douglas Cherry*, *Andromeda*, and *Azalea mollis*, would give you a great variety as well as a long season of flower in these things alone. Of flowering plants and herbaceous things in particular, you may employ any of the Sunflowers. The Pampas Grass and *Arundo conspicua*, with one or two groups of Bamboos, would also be effective. Other useful tall plants are the *Miramelius* Dahies, the *Novi Belgii* and *Novae Angliæ fornis* particularly, with *Polygonum molle*, *Geconia conchata*, *Eremurus robustus*, *E. himalaicus*, *Delphiniums*, *Tritoma Uyaria*, *Rudbeckia Golden Glow*, and *Helianthus*. These are mostly tall things of from 3½ feet to 5 feet in height, and in large groups produce a telling effect. Dwarfier subjects of 2 feet to 3 feet would include *Aster Amellus* in variety, *A. acris*, *A. N. B. densus*, *Alstromeria aurea*, *Stenactis speciosa*, Day Lilies generally, *Paeonies*, *Lenten Roses*, *Flug Irises*, *Japan Anemones*, the white and red *Perennial Pea*, *Helianthemum pumilum*, *H. autumnale*, *Columbines*, *Pentstemons*, *Lilium caeruleum*, *L. candidum*, *L. tigrinum*, *Baltonia canticans*, and the like. Of still dwarfier growth are *Heucheras*, *Iris pumila*, *I. indicaulis*, *Aubrietias*, *Double Arabis*, *Campanula carpatica*, *Perennial Canterbury*, *Saxifraga Wallacei*, *S. granulata plena*, *S. ceratophylla*, *Megasea cordifolia purpurea*, *M. crassifolia*, etc. Of bulbous plants you may now plant *Wood Anemones*, *Cyclamen*, any of the host of *Daffodils*, which in your case may be planted freely. In much the same way a free soil could be made of *Muscari*, *Leucojums*, *Anemones* of the hortensis group, also *A. coronaria*, *Tulips*, particularly those of the Gesner and Parrot kinds, and other things. For the first year *Foxgloves* and *Evening Primroses* would be very pretty if rather thinly interspersed throughout the borders, and would come at a time when their presence would be of service. In short, there is no lack of material for such a place, and with good culture the borders may be made quite a success. If sufficiently sunny you may find room for a few good Pillar Roses, or such a Rose as *Crimson Rambler* on strong poles would be very striking amid the abundant greenery present at its time of flowering. The whole of the things could be planted forthwith.]

NOTES AND REPLIES.

Pollarding an Oak.—As a reader of *GARDENING*, will you kindly reply to the following: Will an oak stand topping? Will it shoot out, like an Elm and other trees, from a head, and hide the places where the limbs were cut? I have two old trees which have grown to a good height, and, being near a wall (about 7 feet high), I should like to lower them, and so reduce the strain; but before doing so I want to be quite sure that they will shoot out, etc. The trees form a ledge, and also a shade for a small dairy.—ALPINA.

[Yes, you can with perfect safety cut down the Oaks. Do this in January or February, but it is to be regretted that such an operation is needless.]

Solanum jasminoides in autumn.—I planted a number of this in the spring of this year to quickly cover some trellis work which I had just formed. I knew it was a beautiful climber, but the way the young plants flower late in the year charms me. Of all the plants in the garden it is the freshest and most beautiful on the first day of November. Even the late Roses, which are so nice, have not the freshness and grace of this lovely plant. It is fully exposed.—V. II.

Wistaria and Jasmine not blooming.—I have a Wistaria and a white Jasmine on a wall facing north-west, in a wide, sloping bed. They do not flower, and the Wistaria looks unhealthy. Can you kindly give me any advice as to treatment?—CARA.

[The position has a good deal to do with the non-flowering of your Wistaria and Jasmine, both of which flower freely enough when grown in a sunny spot, as the wood is then thoroughly ripened, which cannot be the case with yours, for as you say they face the north-west they will get very little direct sunshine. Pruning is also greatly against the flowering of Jasmine, which never blooms so well as when allowed to ramble at will over an arch, verandah, outhouse, or in some similar position. With regard to the unhealthy state of the Wistaria the roots must be at fault. Possibly, owing to the sloping nature of the bed, they do not get sufficient nourishment, and often when walls are built all kinds of old brick rubble are buried at the base, and this is by no means a desirable rooting medium for such a growing subject as the Wistaria. If your plant is small the better way will be to lift it and replant, after taking out three or four barrow-loads of the soil and replacing it by some good compost, such as clopped turves from a meadow, a little thoroughly decayed leaf-mould, and some manure. When planting, tread the soil firmly and arrange it so that there is a basin around the stem to allow of watering, if necessary. If this is done the plant will probably be rather late in starting into growth next spring, but as soon as it does start the young shoots will make rapid progress. Should the plant be too large to lift you might try making a basin around the stem to allow for artificial watering, and if this is done when necessary during the growing season, we think the unhealthy state of the plant will disappear.]

Shrubs from cuttings.—Cuttings of a great many shrubs will root well if placed in the open ground. A fairly sheltered position, in an open, somewhat sandy soil that does not suffer from drought during the summer, is best for the purpose. A heel of old wood is not necessary to their well-doing, yet, at the same time, fairly stout shoots must be chosen; otherwise, many will perish.

THE NEW HORTICULTURAL HALL.

WITH eager anticipation we opened the book of plans of the Royal Horticultural Society's proposed buildings in Vincent-square. We deeply regret that we can only view them with a sense of disappointment. The result is a building entirely commonplace, absolutely wanting in all architectural feeling. The only ingenuity it displays is in giving a maximum of space to the Exhibition Hall, but it is entirely without charm, such charm as is only given by the clever planning, careful detail, and fine sense of proportion that the architect who is master of his craft gives to a building; thus endowing it with the qualities of beauty and gracious beneficence, while not in the slightest degree depriving it of utility. In the proposed plans what have we? The glass barrel of a railway station, masked by a second-rate railway hotel on the road front! In the Exhibition Hall we regret the iron roof and the ugliness of it all, all the more because it is so absolutely needless. Outside we regret the want of simple dignity and proportion, the curiously unhappy fenestration, the lack of every quality a building should possess to be called good. We hoped to see such a building as would do credit to the Society, and can only express regret when we see plans that we can only think unworthy of the Royal Horticultural Society's position and purpose; wasteful of good money, whose same amount might easily have brought both additional convenience and infinitely greater honour.—*The Gardener*.

ROOM AND WINDOW.

PANICUM VARIEGATUM

WHERE indoor decoration is carried out on a large scale, plants of a trailing or pendulous habit of growth are necessary for furnishing vases and stands, and this Grass is invaluable for the purpose, its habit of growth and distinct variegation being perfect. To get a good specimen, insert three cuttings in a small pot—say, a 60—and, as soon as they get a few inches long, peg them down close on to the soil, when they throw up a number of side shoots and form excellent plants without any further training. If larger plants are desired, these can be potted on from the small pots as may be

ance. Plants, in order to be the best suited for table uses, should be grown on from the seedling state or from quite small divisions, so that the growth is concentrated in the one crown. Plants intended for this purpose should be set aside so as to preserve them intact. They should not be overpotted in any case; this is a mistake. Where it is possible a marginal line of *Selaginella denticulata* may with advantage be pricked in around the rim of the pot, but its growth should not be allowed to exceed reasonable limits.

Pampas Grass.—The plumes of the Pampas Grass are known to many, and at Christmas time are frequently used in the

Panicum variegatum as a vase plant.

necessary. For the fronts of stages in warm-houses plants in 48 pots are very effective.

FERNS AS TABLE PLANTS.

MANY Ferns, some of which are quite unique in their way, are very suitable as table plants. Take, for instance, a well-grown Silver or Golden *Gymnogramma*, or the same of *Adiantum Farleyense*; these are each quite distinct from anything else that is usually grown or accepted as table plants. In many ways Ferns are exceedingly useful when in pots from 3 inches to 6 inches in diameter. In order, however, to have such plants in the best condition they should not be crowded together or be in any way overshadowed by other and larger plants. What is wanted is a symmetrical well-balanced plant not in any case drawn on one side. Again, plants of dense growth are not so desirable on the whole; for instance, a plant of *Adiantum Farleyense* or of *A. cuneatum* when in this condition (the whole of the surface of the soil probably covered with rhizomes) would present too heavy an appear-

ance in many a scheme for decoration. How few grow it when one comes to look round amongst our acquaintances. It is, however, easy of culture, often thriving on poor, sandy soils, where other subjects planted out fail. On carriage drives and in shrubberies amongst shrubs, etc., its feathery plumes show up to advantage. Let it once become established, it needs little trouble beyond an occasional top-dressing of manure in winter.—TOWNSEND.

Primula obconica.—For a light, sunny window or cool greenhouse, *Primula obconica* still maintains its popularity, notwithstanding the objections of a few as to its liability to impart a rash to the skin by contact with the foliage at certain times of the year. It blooms for months together, and its blossoms are useful for making up into coat and dress sprays. Seed should be sown in February in the same manner as one would *Primula sinensis*, growing in cold frames until autumn. So treated plants will give plenty of bloom during the winter. (S. F. D.)

FRUIT.

GRAZING IN ORCHARDS SPRAYED WITH POISONOUS WASHES.

POISONOUS solutions are used on the farm for various purposes, such as the destruction of animal parasites (sheep dips), the prevention and cure of animal diseases (copper sulphate in the treatment of foot rot), the destruction of weeds ("weed killers" and sprays for destroying Charlock), the destruction of insects on plants (fruit-tree "washes"), in the form of poisonous baits for the destruction of injurious insects (scattering poisoned Clover, Lucerne, etc., over fields for the destruction of surface caterpillars). Poisons are also used in other forms, for instance, powder (Hellebore), or vapour (cyanide of potassium fumes). Though cases have been recorded of animals having died through eating Grass contaminated by the dripping of recently-dipped sheep, and it is conceivable that injury might also arise when copper sulphate is employed as a foot dressing without due precaution, yet with ordinary care the poisoning of pasture in this way should be impossible. There is no recorded case, so far as is known, of injury having been caused to live stock by their breaking into fields where the crop has been recently sprayed with a solution of copper sulphate.

"Washes" applied to standard fruit-trees can only, except by accident, get into the system of animals in large quantities, when the ground underneath the trees grows a crop of Grass or other fodder crop on which some of the solution may fall and be eaten with the crop. How much of the solution may reach the ground will depend upon a variety of circumstances, such as the quantity of "wash" applied, the state of foliage, the density of stocking of the trees, etc. These factors are difficult to estimate, but it might appear probable, under certain circumstances, at least, that herbage in orchards treated with arsenious compounds, such as "Paris Green" or "London Purple," might become so poisonous as to be dangerous to live stock, although no case of such poisoning appears to have been recorded. That no evil results would follow this method of destroying orchard pests had been already anticipated, and this had, in fact, been experimentally tested in the United States, where Professor Snow sprayed Clover with an ordinary Paris Green wash and then immediately fed his horse on it without any ill effects.

In view, however, of the great increase in recent years in the practice of "spraying" in this country, the Board of Agriculture considered it desirable to make arrangements with the South-Eastern Agricultural College, Wye, to investigate the matter, and an experiment to test the effect of pasturing stock in an orchard sprayed with an arsenical solution was accordingly carried out during the past season by that college. On May 23rd, 1902, two acres of young fruit-trees were sprayed with Paris Green; not only were the trees thus treated, but the Grass between the trees was also sprayed. The wash used was prepared by mixing 3 lb. of Paris Green (Blundell's paste) and 3 lb. of lime with 600 gallons of water. About 3 lb. of Paris Green was thus sprayed over the two acres, 600 gallons of wash being put upon the trees and ground, which is rather more than would have been normally employed, and considerably more of the wash went on the Grass than would have been the case in an older orchard, or where hand machines were used for young trees. The machine used was a one-horse "Mistifier," which sends out a dense and even spray. The plot was sprayed between 1 p.m. and 4 p.m. on a warm, cloudy, still day, the ground beneath the trees being covered with a good growth of Grass. No special care was taken, and as the wash was mixed on the plot, several concentrated patches resulted where the machine was filled from the mixing receptacle. While the washing was in progress twenty Kent ewes were turned on the land and at once commenced eating the wet Grass. The sheep were examined from day to day. On May 24th all the animals were quite normal, feeding and chewing the cud. On the following day the ewes were again visited, when some of them appeared rather ill, and a few were scour-

ing. On the 26th the only further alteration in their condition was that a few more appeared to scorch. Several sheep, however, in the same orchard, on Grass which had not been sprayed, showed similar symptoms. On all subsequent dates, when visited, the sheep presented quite a normal and healthy appearance. The last examination took place on June 7th, and the sheep were found to be in excellent condition. They were then removed from the treated plot.

The result of this experiment corroborates the observations of practical men and also the results and conclusions derived from similar trials conducted years ago in America—namely, that stock may be kept on land where trees are washed with arsenites.—*Journal of the Board of Agriculture.*

BARK SPLITTING.

RECENTLY MR. G. Woodward, of Barham Court Gardens, whose trees and fruit suffered so terribly from the hailstorm that devastated the district of Wateringbury, Kent, exhibited specimens of shoots or branches cut from trees which showed the effects of the hailstones on the bark in splitting it down vertically. The object of showing these branches was to ascertain how best to deal with such injury. The chief danger in such case is that the severe splitting may lead to canker, seeing that every wound opens up excellent openings for the access of the canker fungus. Mr. Woodward desired to learn how best to deal with the trouble, whether it was best to prune back entirely to sound bark, or to coat over the injured bark with some air-excluding substance. As the branches were passed on to the Royal Horticultural Society's scientific committee, it will be interesting to learn what advice that body may have given. But seeing that all the splitting in the bark was vertical and not transversely, I pointed out that apart from the possible incursion of the spores of the canker fungus, there was little doubt but that nature would soon close up and heal the injuries, because sap flow would not be at all checked. Had the splitting run round the shoots or branches so as to divide the bark entirely and have stopped sap flow, all the shoots might soon die. Mr. Woodward proposed to coat the injured branches with a mixture of cowdung or clay, sulphur paste, and paraffin, which would exclude spores and air, yet not check the production of inner bark growth, leaving the rest to nature. I suggested that it would create special interest in the experiment were some of the trees—they are chiefly bush Apples—cut hard back and some left untouched or undressed. The injury is of an unusual character, but as it may occur to anyone else at any time, the ultimate effect of remedial or other treatment can hardly be made too widely known.

How very diverse is the cause of bark-splitting referred to by a correspondent, on page 420, who shows that his trees have had their bark split on the hot or sunny sides. The injury in this case, there can be no doubt, is due to scorching, the sap in the woody cells being so heated that it burst the cellular tissue, and thus caused the cracking. Where that form of injury is prevalent, although it is so in very few places, it is obvious that some protection should be given to the bark on the sunny side. That could be done by tying some Furze or Fir branches round the stems during hot weather. When visiting Mr. Woodward's fruit-garden last year I noticed a precautionary measure on his part such as I do not remember to have seen elsewhere. He had pieces of Cork-bark fixed close to the front or sunny sides of the main or lower stems of all the wall fruit-trees that faced the sun. He holds that just at that point of the tree where the sap flow is concentrated scald or scorching is apt to take place, leading to the flagging and ultimate death of some branches, and, in time, of the entire tree. In any case, whether that assumption be correct or not, furnishing this stem-protection did present itself to me as a very simple yet practical one. There is another occasion when bark protection is essential, though not from sun-heat, but from frost. It is when Vines that are planted on an outside border are forced into growth inside the house early. Then because all the sap flow from the

roots is centred in these exposed stems it is important they should have protection from frosts until the outer temperature has materially risen. That could be done by winding hay-bands round the stems. Vines early forced, having had their stems frosted, have flagged badly, and at times are severely injured.

A. D.

FIGS.

THE theory set forth in the communication from "H. N. G., Bath," on page 423, seems to me to be very far removed from actual fact. Barren Figs have been known since Bible times, but their barrenness often is the outcome of unsuitable surroundings, climate, or culture. Though your correspondent cultivates one hundred trees under varying conditions he limits his selection of varieties to three—certainly a small one for so large a number of plants. As pointed out in the notes on page 383, there is a fine collection of varieties grown in the Royal Horticultural Society's gardens, and when examining these I could not distinguish between them in their freedom of fruiting. Nor could one fail to be struck with the small size of the pots so many of the plants occupy. Figs may very easily be rendered unfruitful by encouraging luxuriance with unlimited root space. Their very nature is to produce fine foliage, and to get useful crops demands restraint of this untoward vigour. To define Figs that never bear any fruit as males, and those which drop, even in fine weather, as females, seems absurd. Probably all and every kind of Fig known to cultivation would display such traits were the cultural conditions such as to encourage rank growth on the one hand, or a starved state on the other. When restricted in pots there is no plant that calls for more feeding than the Fig, that is, if fruit is the primary object of its growth, and, as is pointed out on page 383, two, and even three, crops may be had during the season, according to their treatment and variety. How, then, can "H. N. G." reconcile his far-fetched theories in the face of such plain truths? It would be well to ascertain in what respect culture has failed to produce mature fruits, and if "H. N. G." will act upon the advice given on the page quoted above, he will in the course of time find that his theories will have misled him.

S.

PLUMS—YOUNG VERSUS OLD TREES.

OBSERVATIONS extending over a lengthened period show the value of young Plum-trees compared with that of old ones. In a hot, dry season, or a dull, sunless one, the young and healthy specimen will mature its fruit, which will be of a good size, while the old and decrepit tree will, at any rate, in the case of some kinds, give that which is only fit for cooking, and not very good for that oven. As I write I have in mind trees that for some years—how many I cannot ascertain—have cropped annually. This season, and for some preceding ones, the fruit has been unsatisfactory as regards size and quality, not as regards extent of crop, for thinning had to be resorted to in order to reduce it to a normal state. Probably, in some of these instances the over-cropping of the trees in their early stages contributed to the loss of vigour. The variety Jefferson is particularly offending in this respect, and though in a young state, and bearing a reasonable crop, the individual fruits of this are large, handsomely coloured, and altogether attractive, yet, when over-loaded, or from an old tree, quality, which is a marked attribute of the kind, is wanting. Well-grown, perfectly ripened, and full-coloured fruits of Jefferson are excellent, but all this can be changed, and, instead, mediocrity follow, if, when the tree is advancing in years, a heavy crop is permitted. Another summer Plum, Kirke's, which is of the highest value and quality, can be just as easily reduced to an almost worthless state. Three years ago, when ordering trees for my own use, I procured some of Jefferson and Kirke's Plums for a neighbouring cottage gardener, and, at the same time, supervised their planting and after-treatment. An early crop was expected, and, what is more pleasant, was realised, the fruit being fine in every way.

When it is remembered that there is abundance of good cooking Plums to be had, and to

retain a tree of a dessert kind whose fruit is only fit for cooking, and so disappoint year by year when its crop is gathered. Trees are not expensive to purchase in these days, for if the means do not allow of the purchase of those which are trained, maidens, which are much cheaper, are available. To the inexperienced, however, the maiden-tree often becomes a stumbling block. It is better to be a little too severe than forbearing when pruning the maiden-tree, as if a good foundation is not laid in the first instance it is not easily brought about afterwards. For this reason, though a little more costly, the trained tree has all-round advantages when placed in the hands of the inexperienced. In the planting of trees it sometimes occurs that blank spaces are available on walls where a young tree may be brought on preparatory to its taking the place of an old one later, and thus while time is in this way saved, a crop, it may be for two or even three years, is secured from the old one. When temporary or permanent planting is done, fresh soil might always be provided, though the change may be made from ground but a few paces away. Good garden soil is strong enough and quite suitable for growing Plums when some lime rubble and burnt earth are added to it. Rich turfy loam may stimulate too vigorous a growth, and the addition of manure would certainly cause this. The late autumn is the best time for moving Plums, and it is advisable in the year after planting not to allow the trees to bear a crop, as in this way the trees become well established for future bearing. An east, west, or south wall suits Plums, and in some cases a north aspect may be utilised to advantage.

W. S.

NOTES AND REPLIES.

Insects on wall trees.—I have a wall garden, with Cherries, Currants, Peaches, Nectarines, Peas, and Plums on the wall. This year I was troubled with insect pests of all kinds. What kind of winter wash do you recommend for use to spray on? I also propose having the walls whitewashed. Would it be advisable to use some insect destroyer with the wash? If so, what? (C. H.)

[A most valuable wash for wall or, indeed, any fruit-trees, to be applied in the winter, consists of caustic soda and commercial potash, in the proportion of 1 lb. of each to 10 gallons of water. Both soon dissolve in boiling water, and it can then be syringed on to the trees whilst hot. If to it be added 1 lb. of soft-soap for each 10 gallons, the liquid is all the more adhesive. You can give such a washing at once, or, at least, so soon as you have pruned the trees. When you do that, collect all prunings and burn them, or otherwise you may still leave near by many clusters of insect eggs. With respect to lime-whiting the walls and trees, that may follow, but we prefer syringing it on thickly rather than using a brush, and adding some clay and sulphur to colour the wash. The hotter that is applied the better. It will peel off in the spring. Use a fine rose to the syringe for the first-named solution, and a coarse one for the latter.]

Replanting viney.—I have rooted out six useless Vines, and intend to put in their place two new Vines, a Peach, a Nectarine, and a Plum, all in barrels. What Vines should be put in to grow with these fruits, and what is the best compost for each? I think of putting in Black Hamburgh Vines, but do not know if the same best will do for these as for the Peach, Nectarine, and Plum.—W. J.

[We do not think you will succeed in the attempt to grow Peaches, Nectarines, and Plums in company with Vines, and the Vines would not long continue to be of service to you restricted to tubs. You do not say, but we presume your house to be a lean-to, having a lofty back wall. In such case you might, if you limited the number of Vines on the roof so that ample light passed between them to the back wall, grow a Peach and Nectarine trained on the wall. We would remind you, in the hands of the inexperienced Plums are uncertain fruits, and therefore advise you to save yourself disappointment. Black Hamburgh is the best all-round Grape to grow; the Peach and Nectarine should be selected to suit your personal requirement—early, mid-season, or late. The best soil for each is a good turfy, calcareous loam, with which are incorporated lime rubble and crushed bones. Should the turf be from poor ground, a little short horse-droppings would be a useful addition. All should be

made firm, whether you use tubs or make a border. The latter course would be much the best, because more lasting, and what is important in the absence of a qualified gardener is the attention needed from day to day. In tubs fruit-trees soon suffer, if they do not hopelessly fail, unless water is given frequently in hot weather, and unless feeding with stimulating liquids is regularly practised. Much of this can be saved if a well constructed border is provided at the outset. Probably your object in adopting tubs is a saving of initial cost, a course we cannot recommend, except, as before mentioned, there is qualified daily attendance. When Vines are grown in an ordinary manner over a roof trellis there is no other-fruit-tree that will succeed in the same house, because of the shade imparted by the overhead Vine foliage. With fewer Vines, and these rigidly trained so that between each there is a clear space for the admission of light and sun, then Peaches and Nectarines may be grown, but even then they would be better on the wall than in pots or tubs. You need not make a full-sized and complete border at once, but make it at the rate of a yard width each year, or every alternate year, which will render

The most they do is to remove much or all of the undergrowth or that which is so near the ground that the fruit cannot be kept clean, a little forebortening sometimes delayed till the fruit is large enough to pick and market, and scarcely any thinning-out being practised. It is the hard pruning that causes the formation of very much more young wood than is desirable, and the market grower's bushes, though large, are never such impenetrable thickets of growth as might perhaps be imagined.—T.

Pears and Plums for walls.—Please tell me of some good Pear and Plum-trees to plant against south wall, Marie Louise excepted? Standard Plum-trees never bear in this garden.—F. R. LLOYD.

[Of Pears, plant Louise Bonne, Josephine de Malines, Doyenné du Comice, and Winter Nelis. Of Plums, if you want cooking kinds, Rivers' Early Prolific, Victoria, and Czar; if dessert kinds, plant Denniston's Superb, Green Gage, and Coe's Golden Drop.]

APPLE AUTUMN PEARMAIN.

This Apple, frequently met with in old orchards in the west of England, is, I consider, one of

about three good shoots next summer. The shoots selected should be long, firm, and straight, be shortened to a length of 12 inches to 15 inches according to their vigour, be cut clean across below the lowest joint, and have all but the three or four uppermost buds cut out and be then firmly dibbled in to a depth of 6 inches.

GARDEN WORK.

Conservatory.—One of the most striking shrubs in the conservatory now is *Luculia gratissima*. It is not often one sees a good specimen in a pot, but plant it out in a bed of turfy loam and peat and the plant thrives amazingly and produces immense trusses of rose-coloured flowers at this season, which continue some time in condition and are pleasantly fragrant. Give it plenty of water during growth, with weak soot-water when flower-heads are forming, and cut rather hard back after blooming. It is not a very easy thing to strike from cuttings, but succeeds better when layered. Cuttings of the young shoots which break away after pruning, taken off with a heel of old wood, inserted in pots of sandy peat under a bell glass, will root in time, but must not be hurried. It is best to keep the cuttings in a moderately cool house, till the bottoms of the cuttings are callused over, and then give a little heat in a close propagating case, but it is very important for the bell-glass to be wiped dry inside every morning, or the condensed moisture will damp off the cuttings. This is important in the case of all cuttings rooted under glass, especially in the confined atmosphere of a bell-glass. One can always gather a few Roses, if free-growing Teas and Noisettes are planted out in the border. Kaiserin Augusta Victoria is producing very fine blossoms now. Safrano is nearly always in bloom, and the buds are very beautiful. Lamarque is a beautiful Rose in a light position under glass. Those who have failed with the Indian Daphnes in pots might plant one of each kind in a good bed of loam and peat or leaf-mould and sand. The bed must be well drained. I have had very charming bushes planted out which filled a large house with fragrance for a long time in winter. They grow very freely planted out, and, of course, produce more flowers. The red variety, *D. rubra*, grows more frooly than the white, though the flowers are not quite so large. Abutilons in variety are very useful winter-flowering plants. These also do better planted out, and trained over arches or otherwise.

Stove.—A well-managed stove is a delightful feature in a garden for those who can bear the moist, warm atmosphere of the tropics. There are times when one has to use more heat and moisture than are necessary for ordinary purposes. A sudden demand may arise for some particular flower and the temperature has to be raised to produce it. There is a great advantage in the possession of a small, close place for such work, and then the ordinary stove may remain at the normal temperature of 60 degs., or a little more at night, whilst the small forcing-house may be run up to 70 degs. or 75 degs. to give a flip to such things as Lily of the Valley, Tuberoses, Gardenias, etc. Many things, such as Caladiums, Achimenes, and Gloxinias, will now be resting or approaching that stage. Caladiums must remain in the warmth, but Gloxinias and Achimenes, if kept dry, will do in a lower temperature. The summer-flowering climbers, such as Allamandas and Bougainvilleas, will be kept drier at the roots, but though these are now flowerless there are other climbers in bloom now, including the scarlet *Passiflora princeps*. *Hoya carnososa* often flowers in winter. *Jasminum gracillimum* is seldom altogether flowerless where it thrives. I have seen *Hexacentris Mysorensis* prettily in flower at this season, and *Ipomoea Horsfallii* is very bright just now, and the old *Begonia fuchsoides*, planted out in a light position, will flower all the winter. The brightest plant in the stove, if planted out and permitted to ramble, is *Euphorbia jacquiniiflora*. This is often a poor, staggling thing in a pot, but plant it out in a light position and give it freedom, and it is a different thing altogether.

Rose-house.—Where Roses are planted out and either trained over the roof or grown

Apple Autumn Pearmain. From a fruit sent by Miss Solomon, Central Avenue, Covent Garden.

the work more easy, and the results, with proper attention, more certain.]

Canker in Apple-trees.—I enclose two cuttings from a Lane's Prince Albert Apple, about four years old. Finding some trees very much in the condition of enclosed, and being ignorant of the cause, etc., I am anxious for some information. Trees were planted early last March, and were clean and healthy-looking. This season's growth looks all right, but in some places springs from branches showing a slightly similar condition as enclosed. Your opinion and advice would be a favour to—ANADON'S ONE.

[Your trees are evidently suffering from canker caused by the roots getting down into a wet, cold subsoil. Open a trench round the tree, sever the deep-going roots, then refill the trench with some good fibrous loam, and place over the roots a dressing of manure.]

Pruning Gooseberries.—Early pruning is a mistake where birds are known to be troublesome, removing a considerable portion of the young wood rendering the clearance of buds on the rest of the bush easy and certain. In all such cases pruning should be delayed either till the most critical period, this being when the buds are just moving, is past, or even a little later. Market growers do not prune nearly so hard as most private growers, and they usually obtain heavier crops accordingly.

the best late dessert Apples in cultivation. It is of fine quality and handsome appearance. Like the majority of late dessert Apples, a warm soil is needed to bring out its highest qualities. It does well either as a bush or orchard standard, but the leading shoots must be shortened sufficiently in the earlier stages of the tree's growth, or the growth will be rambling. T.

Pruning Black Currants.—Thinning out and freshening are principally what have to be done, the fruit being borne on the young wood formed the summer previous. In order to keep the bushes well within bounds, cut back the straggling outside and leading branches to better placed inner shoots, and then thin out the remainder of the young shoots so as to have them thinly distributed all over the bush. Quite young bushes should be freely cut back for at least two winter prunings, this being the surest way of laying a good foundation. Always keep the centres a little thin. Cuttings made now from young wood and inserted not less than 6 inches apart in rows laid asunder on an outside border will most probably all strike root and form

as bushes, the lights should be taken off in July to ripen the wood, and anyone building houses for Roses, if he means to plant them in beds, should have movable lights. If the plants are grown in pots they can be moved into the open, plunged in ashes, and left for a time to rest and recuperate. There are some advantages in having the plants in pots, as the house can be used for another purpose from the first of July to October—time enough to take a crop of Tomatoes if it is necessary to make the most of things. Then, again, if the plants are grown in pots, the beds in November may be filled with leaves and the plants partially, if not wholly, plunged in the leaf-bed. This little bit of genial root-warmth adds immensely to the vigour of the plant and the consequent size and number of the blossoms, and there is less trouble with insects and mildew. I need hardly say that everything about the Rose house should be clean. Mildew spores and insect eggs may remain in and about the house, and before the roses are brought back the woodwork and walls should be thoroughly cleaned. Of course, the vaporiser will make short work of the green-fly, but a strong effort should be made to clear out every trace of mildew.

Forcing Strawberries.—It is of no use attempting to force these very early unless the crowns are well developed and ripened, and the pots full of roots. A low pit furnished with a bed of fermenting leaves, with a night temperature of 50 degs. to begin with, is an excellent starting place for Strawberries at this or any other season. Be careful with the water-pot at the beginning, or there may be leaf-growth too much in advance of the blossoms. Ventilate to meet the rise of temperature, and fertilise daily with camel's-hair-brush or the rabbit's-tail when the blossoms open, and thin to a dozen fruits when enough has been set.

Window gardening.—Keep Cactuses and other succulents dry during winter. Fine-foliaged plants, such as Ferns, Palms, and Aspidistras, will require less water, still, when water is necessary, a thorough soaking must be given. When a plant has been allowed to get too dry submerge it in a pail for a time till the air bubbles cease to rise. Bulbs coming on must be kept moist.

Outdoor garden.—There has been a wonderful autumn bloom of Tea Roses. Dr. Grill, La France, and the Hybrid Teas have been very fine. Good drainage is very important for Roses, especially for Teas, as it helps the maturation of the growth, and consequently by hardening the plants makes them less susceptible to injury from a low temperature. There is more in this matter of drainage and its hardening effect upon Tea Roses than what is generally thought. Of course, when the drainage is perfect there must be a considerable depth of good soil, or the plants may suffer from drought. If we get severe weather, as a precautionary measure dwarf trees may be earthed up a little, say, 4 inches or 5 inches. If the tops get badly frozen they will break very strongly from the bottom. An inch of good loam will be a great help to beds of Carnations recently planted in checking the lifting power of the frost. Many plants die from disturbance by frost rupturing the roots. Box edgings may be replanted when the weather is suitable, and if Moss-grown or weedy walks are turned over and well rolled down a neat and tidy appearance will be secured at a comparatively small cost. Box edgings are not so much used now in town gardens. Staffordshire tiles are more lasting. Those who appreciate the picturesque may use rough, hard stones, and plant dwarf, creeping plants inside, to grow over and partially cover them. All alpine plants or other hardy plants in pots should be plunged to the rim in ashes, and, if possible, covered with old lights.

Fruit garden.—The autumn is the best time to lift Vine roots and re-make the borders. The work is too heavy to do it before it is necessary, but when there is a falling off in the produce of the Vines it is time to see what is wrong with the roots, and the bold course is generally the best. Those who have had much to do with Vines under glass do not hesitate to lift the roots and re-make the borders when its necessity becomes evident. Vines are hardy, long-suffering plants and a

recover from any little injury done to the roots during renovating operations. If the borders are wide, they need not be all made at once. Six feet of good soil is enough to start with. Any land that will grow good Wheat and Beans will grow good fruit, but for Vine borders take the top 6 inches from a sheep pasture. This alone when in a mellow condition will grow good Grapes, but, to obtain the best results, add $\frac{1}{2}$ cwt. of bone-meal and a couple of bushels of old plaster to each cartload. Anything in the nature of chemicals can be given later if one believes in them, and they are useful at times. When pruning Vines, select a few of the cuttings and lay them in for propagating. It is well to keep heavy rains off Strawberries in pots, but they must not be permitted to suffer from drought.

Vegetable garden.—Make up Mushroom-beds from time to time as vacancies occur in the house. Keep all the spaces filled and there will not be much fire heat required, as the warmth of the beds will be sufficient to keep up the requisite temperature. Open air-beds are still bearing freely. Waterproof covering must be used now, and, when any bed requires water, give it warm and fortify it with a little salt occasionally, with a little nitrate of soda or other stimulant as a change. Clear up the rubbish yard, and convert all cuttings, hedge trimmings, etc., into manure by smother burning. Make this heap as large as possible by adding lumps of clay to the fire, or anything that will smoulder or decay. There is plenty of leaves and other material for making up hot-beds for forcing Rhubarb, Seakale, and Asparagus, or making up light beds for Lettuces, Radishes, etc. Early Potatoes may soon be started in boxes or in single pots for turning out on hot-beds by-and-by. For good and early crops we find nothing superior to Duke of York. All we know who have grown it give it a good name as a forer and for planting outside. For early planting, sets should be placed crown upwards in shallow trays or boxes, and stood in a light position safe from frost. Sow a few Tomato seeds of a good early kind thinly in shallow boxes on a shelf in warm-house. E. HOBDAV.

THE COMING WEEK'S WORK.

Extracts from a Garden Diary.

December 8th.—As soon as the wall trees are pruned and trained they are thoroughly washed with a solution of soft soap and paraffin oil. The offspring of the flies are concealed either on the wood or in the wall, and a thorough washing will get rid of a good many. One of the walls which has been broken about with much knocking in of nails will be pointed and washed over with lime and sulphur.

December 9th.—Looked over late Grapes to remove bad berries. There are no plants in this house, nor will be until the Grapes are cut, and the inside borders are covered with dry litter to keep down and check evaporation. Pulled up the largest of the Turnips and laid the roots in trenches deep enough to cover the bulbs, the foliage being exposed. This is the best way to store Turnips in winter.

December 10th.—The fruit store is often looked over to remove decaying specimens. The best late Pears have been carefully placed in drawers and shallow boxes, and kept dark. Potted a few Tuberoses for early blooming. Others will be potted in succession, and as Tuberosa blossoms are wanted they will soon be placed in heat. A few of the earliest and best prepared shrubs in pots have been placed in heat for forcing into blossom.

December 11th.—Lawns are rolled after rain, when the turf is soft. A mossy or weedy walk is turfed over, the gravel raked into position, the surface trodden, and then rolled down firmly. Sometimes it may be necessary to add a sprinkling of fresh gravel before or during the rolling. Globe Artichokes have been covered with litter and a light covering of soil placed over the litter to keep it in position. The Globe Artichoke is not perfectly hardy in this country.

December 12th.—Bulbs and forcing shrubs are being gradually moved forward to bloom in the conservatory. Good strong roots of the

Bleeding Heart (*Diclytra*, to use its old name), if well established in pots, will bloom without much forcing. It is not every plant that will stand forcing, but this will if established. Rhododendrons in bud may now be potted up, kept cool for the present, and then grown on in heat for conservatory.

December 13th.—Moss-litter manure has been used freely as a mulch among herbaceous plants, bulbs, etc. Potato clamps have been covered with long litter to keep out frost. Sets for planting are being placed in shallow boxes, early kinds only at present. We are still finding new positions for Roses, especially climbers that will take of the stiffness of the place. Started a few dozen Royal Sovereign Strawberry in a gentle heat for early crop.

LAW AND CUSTOM.

Entry to repair fence.—A fence of Oak paling belonging to the owner of garden No. 1 separates garden No. 1 from garden No. 2, and has been in its present position over 22 years. When the fence was made garden No. 2 was a grass field, and since that time the fence has been repaired when necessary by its owner, who entered upon the field for this purpose when he found it necessary to do so. The fence now requires repair, and such repair cannot be executed without entering garden No. 2. Is the owner of No. 1 the right to enter upon garden No. 2 for this purpose, entering that garden from a side passage at a reasonable hour of the day, and without seeking permission so to do? If an action of trespass were brought by the owner of garden No. 2, in what court would the action be tried?—*ALBION.*

[Upon the facts stated it would almost seem that a right of entry for the purpose of repair when repair is necessary must be presumed to have been granted to the owner of garden No. 1. But it does not follow that, although repairs are necessary, the entrance must be from an extraneous entrance to garden No. 2. Generally speaking, entry from garden No. 1 will be quite feasible either over or through the fence in question, and indeed it is quite possible that the repairs are capable of being executed without entry upon garden No. 2. In that event I think the owner or occupier of garden No. 2 might bring an action of trespass against the owner of No. 1, and such action would ordinarily be tried in the county court. The owner of No. 1 should not attempt to enter No. 2 unless such entry is absolutely necessary. It would not be a defence to urge that it would inconvenience him to do the work from his own garden.—K. C. T.]

The Ground Game Act.—Farmers and the trapping of rabbits.—Can a shooting tenant stop the occupier of the land from trapping rabbits when the occupier has the permission of his landlord to trap rabbits where, when, and how he chooses?—*SOMERSET.*

[The Ground Game Act of 1881 gives an occupier of land the right to kill and take rabbits on such land, and no matter whether the rabbits are or are not reserved to the landlord or his shooting tenant, or whether the occupier has or has not permission from his landlord to kill rabbits, he may kill rabbits if he chooses, and no one can prevent him. He may kill them by shooting, trapping, ferreting, coursing, netting, or in almost any way possible except by poisoning; but as to trapping, he may set traps in rabbit holes only, he may not set traps in open ground. When the occupier possesses only the rights given him by the Ground Game Act, and apart from that Act has no right to the rabbits (as if the right to the rabbits is expressly reserved to the landlord in the agreement of tenancy), he may kill and take ground game—that is, hares and rabbits—only by himself, by the members of his household resident on the land in his occupation, by persons employed by him in his ordinary service on the land, and by one other person (such as a professional rabbit-catcher) *bona fide* employed for reward in the taking of ground game. And the occupier must give each person who kills ground game for him a written authority so to do. Further, only the occupier himself and one other person may kill ground game with firearms, and that other person must be specially authorised in writing by the occupier to kill ground game with firearms. Now I rather imagine from your question that you wish to kill rabbits in some way not permitted by the Ground Game Act, as, for instance, by setting traps in open ground by a number of people not members of your household or ordinarily employed by you on the land, and if this be the case and you want

further advice on this matter, you must say exactly what you want to do, and what it is the sporting tenant objects to. I may as well add that, while the rights given the occupier by the Ground Game Act are indefeasible—that is to say, he cannot be deprived of such rights by any agreement or stipulation—they are not absolute; they are concurrent—that is to say, they exist or run together with the rights possessed by any other person, and so both you and the shooting tenant may have and exercise the right to kill and take rabbits and hares.—K. C. T.]

CORRESPONDENCE.

Questions.—Queries and answers are inserted in Gardening if change of correspondence follows these rules: All communications should be clearly and concisely written on one side of the paper only, and addressed to the EDITOR OF GARDENING, 17, Furnival-street, Holborn, London, E.C. Letters on business should be sent to the PUBLISHERS. The name and address of the sender are required in addition to any designation he may desire to be used in the paper. When more than one query is sent, each should be on a separate piece of paper, and not more than three queries should be sent at a time. Correspondents should bear in mind that, as GARDENING has to be sent to press some time in advance of date, queries cannot always be replied to in the issue immediately following the receipt of their communication. We do not reply to queries by post.

Naming fruit.—Readers who desire our help in naming fruit should bear in mind that several specimens in different stages of colour and size of the same kind greatly assist in its determination. We have received from several correspondents single specimens of fruits for naming, these in many cases being unripe and otherwise poor. The difference between varieties of fruits are, in many cases, so trifling that it is necessary that three specimens of each kind should be sent. We can undertake to name only four varieties at a time, and these only when the above directions are observed.

PLANTS AND FLOWERS.

Rose Baltimore Belle (W. B.).—This Rose is not much grown in England, but in America it has a good reputation. It is best grown as a climber, having it unpruned, simply allowing it to grow in its own way. The flowers are pale blue, variegated carmine, rose, and white. They are very double, produced in clusters, and when well established it is a mass of bloom.

English Iris from seed (F. B. C.).—Sow the seeds in sandy loam, covering the seed about a quarter of an inch. Make the surface level and firm, and on this spread some sand, and then sow the seed. It will not germinate till next spring. See that the soil does not get too wet or the seeds will decay. If you have only a few seeds, you could sow them in a pot or pan, covering this with a sheet of glass, and standing in the greenhouse or in a cold-frame.

Slug-infested soil (Acad.).—Slugs are found to be most about the bases of walls and it will be a good plan if you fork away several inches of soil from near the walls, and dress thickly with fresh slaked lime, then replace the soil. Your best remedy, when they are out feeding in the evening, is to dust the crops freely with fresh lime and soil, as that soon kills the pests. Leave your Roses as they are until March, and then cut down as your friend advises you.

Moss on lawn (P. Kilmoch).—In the early spring tear up the Moss with a long-toothed rake, doing this at twice, allowing a week to intervene. In the early part of March dress the ground with good loam, some rotten manure, and wood-ashes, with about one-sixth part of lime; then sow with a mixture of good Grass seed, not that from a hay-loft. You will not be able to use the lawn for tennis till late in the season; in fact, it would be better to cease playing tennis on it for a season.

Forcing bulbs (P. O. B.).—Where bulbs have been potted late, and flowers are wanted as early as possible, there is always a temptation to place them in heat earlier than one ought to do, and so, instead of good spikes of flowers resulting, only indifferent blossoms appear. Last time cannot be made up, as several weeks should elapse from the time of potting to the period when the bulbs are brought into heat, so that roots may have well formed, and it is therefore much better to have good late flowers than weakly early ones.—LEARNER.

Rose Marechal Niel in greenhouse (W. D.).—It will be advisable to keep the plant on the dry side until new growths are about an inch long, then you may give the border a good soaking of water. The cooler you can keep the plant now the better; but when new growths appear from the long canes you must be very careful as to ventilation, so that no cold draughts which would chill the plant are caused. Very little pinching is needed beyond retaining the unripened ends of the long rods and shortening back the lateral growths to two or three eyes from the main stems.

Heuchera seedlings (Wentzger).—It were better had the young plants been picked out some time back into other beds snugly at a short distance apart. This indeed, may be done now, keeping the loam in a frame for the winter, and planting out in March. If you now prick out or transplant into shallow boxes, say 2 inches apart, you will in spring be able to plant the seedlings in groups or in a bed to prove them. By doing what is suggested, you will be enabled to transfer the young plants with small lots of roots, and so gain materially to point of time and size of plant. In the transplanting a dozen may be arranged over an area of, say, 2½ feet, and thus form a showy group. The flowers are nearly bell-shaped and about ½ inch in length, numerous disposed on stems 2 feet high or more. The colour ranges from white and pink to brilliant scarlet.

Telopea speciosissima (R. G. Stone).—This should be sown in about two parts of peat to one of loam,

and rather less than one part of sand. In the case of a 6-inch pot put the crocks to about one-third of its height, and fill with the prepared soil. On this sow the seeds, and cover with about a quarter of an inch of the same compost, place in a shady part of the intermediate-house or the warmest part of the greenhouse, and keep watered. When the young plants come up and form two or three leaves beside the cotyledons, pot them singly into small pots, using the same compost. The Waratah is essentially a greenhouse plant, but it may be placed outside during the summer. You will, in all probability, have to wait some years for this to bloom; indeed, as far as our knowledge extends, it has only flowered two or three times in this country.

Cilanthus Dampieri (W. C. Storey).—This is a very difficult plant to grow in a satisfactory manner. The seed should be sown singly in small pots in a mixture of equal parts of loam and peat, with half a part of sand. The reason of sowing singly in small pots is that the roots are so impatient of being disturbed that if sown together and potted off afterwards most of them would be likely to die. If you have plenty of seed, a good plan is to sow two or three in each pot, and directly the plants are sufficiently advanced to detect the most vigorous, pull out the others, and leave the best in sole possession. A genial, yet airy greenhouse is the best place for this Cilanthus, and as soon as the young plants are sufficiently advanced they should be shifted into pots 4½ inches or 5 inches in diameter. Much the same soil, except that a rather less amount of sand is needed, will suit them well. As the plants grow they may, if necessary, be shifted into 6-inch pots, or they can be flowered in 5-inch ones. As the pots get full of roots a little weak liquid-manure will be of service. The flowers are so beautiful as to well repay any little extra trouble taken in the cultivation of this Cilanthus.

Rose plants infested with mildew (Elic).—An excellent recipe for the cure of this troublesome fungus is as follows: 2 lb. sulphur, 2 lb. sulphate of soda, 4 gallons of water, boil for three hours; add pint of paraffin when left off boiling. To use: A small thumb-potful to 2½ gallons of water. Apply with a good syringe. This would not be of much use during the resting season; but you should prepare some another spring in readiness to apply as soon as the fungus manifests itself. Lime and soot sprinkled over the beds would do no harm to the small plants if applied in moderation, and it would be of much value to the herbaceous border. Before dressing the Rose-beds remove about ½ inch of the surface soil and burn it, then apply again to the beds, taking care to turn at same time any mildewed growths which are usually found at the base from a mode of growth of some varieties, such as Mme. G. Luize, Her Majesty, etc. We are gradually obtaining a mildew-proof race of Roses, and additions to their number will be warmly welcomed by Rose lovers.

Plants for beds (A. B. C. D.).—For the centre bed B we would suggest a margin of yellow Crocus, filling the centre with Tulip Yellow Prince, and freely planting a Tuffed Pansy on the surface. In the side beds, C and D, you could plant white Tuffed Pansies, with scarlet Tulips; while in border A white Crocuses may be planted, with Aubrietia or the double white Arabis. In place of the Tulipa Anemone corollaria will make a most showy bed and flower well. These are also very cheap by the 100, and may be planted 6 inches apart and 4 inches deep. In summer you have the option of many annuals, such as Iberis or Candytuft, Dianthus, Antennaria, Stocks, Zinnias, Mignone, etc., or Ivy Felagoulums, or Verbenaas potted down, or tuberoses Begonias in a mixture, single kinds being especially good for bedding. These last are well suited for late planting, and for flowering alter the other things named. Any good soil, with manure added and deeply dug, will grow these things quite well. You should have no difficulty in growing the Rose Crispus Rambler. It requires a deep rich soil, and should be planted against a wall with south-west aspect or trained to a tall stake or support. The variety should be grown on freely, and when long rods are formed allow these to flower without pruning.

Lilium longiflorum the second year (Bury).—Whenever this Lily may be treated, you cannot expect it to flower as well the second year as the first. The greatest measure of success is obtained in landing the plants out-of-doors in a sunny spot after the blossoms are past. They must be watered when necessary till about the middle of September for even earlier, when many of them will show signs of going to rest. After this no more water will be needed, and as the stems die down turn them out of the pots, remove as much soil from the bulbs as you possibly can without injuring the roots, and repot. After this they may be stood in a sheltered spot out-of-doors or in a cold-frame. This latter is the better, as the lights help to keep off heavy rain, and water must be sparingly given till the roots are again active. Later on the plants may be shifted into the greenhouse. Many cultivators obtain a fresh supply each year, and plant out the old bulbs after flowering in the herbaceous border, in the foreground of shrub or similar spots. In the case of your plants you had better see that the drainage is right, clear away some of the surface soil, and add some good rich material, standing them on a shelf in the greenhouse.

Propagating Pinks (R. G. Stone).—The propagation of the Pink is effected in a variety of ways, each and all having their advocates. Perhaps the most common way is by taking cuttings, or what are more generally known as pipings, striking these in pots of fine sandy soil. Others adopt the more rough-and-ready, though not so satisfactory, plan of dividing old clumps into tiny tufts and planting these out in well-prepared beds where they are to flower. These separate portions do not take quickly from the base, and produce a good many blooms the following season. The best plants are had by simply layering in the same way as Carnations. A little extra time and care are needed, as the old clumps are somewhat dense and need thinning out, so as to allow of the fine leafy, woolly soil being worked in and the knife used. Some who require only a few plants place soil round the old clumps and layer only from the edges. Stems having several healthy growths on are selected, and thus fine stocky plants are secured for early autumn transplanting. Layering is best done when the plants are two years old, before the growths become crowded, and the stems are flowering the north wall is the best, and it is

imperative that plenty of coarse sand or road-grit be mixed with the compost. Early propagation is very important, so that the plants be set out in the autumn, and thus get established before the winter.

TREES AND SHRUBS.

The Holly-fly (Mrs. Hodson).—Your Holly is attacked by the grubs of the Holly-fly (Phytomyza aquifolium). It is a very difficult pest to deal with, as no insecticide can be made to reach the grubs, safely enounced as they are between the skins of the leaves, which are very hard and stiff, and the transformations of the insect are all underground within the leaf. The flies lay their eggs under the skin of the leaves in May or June. If the exact time of the appearance of the flies could be found out, it might be possible to prevent them from laying their eggs by spraying the leaves with paraffin emulsion, taking care to spray both sides. The leaves would have to be kept under the influence of the wash for several days. The only other remedy is picking off the infested leaves and burning them, which would be almost as difficult to accomplish as the spraying.

FRUIT.

Keeping Nuts (North Wales).—Thoroughly dry the Nuts, then store them in large earthenware or stone jars with lids, and on top of the Nuts put 3 inches of sand or Cocoa-fibre, and keep the jars in a cool cellar. In this way we have seen Nuts kept till they come in again.

A winter wash for fruit-trees (R. D. O'Brien).—For making a small quantity dissolve ½ lb. of caustic soda in a gallon of water, then add ½ lb. of commercial potash (pearlash), stir well, then mix both, adding enough water to make 5 gallons of solution. Apply to the branches and stems of the trees with a syringe or engine when the trees are dormant.

American blight on Apple-trees (T. M. B.).—Your trees are attacked by this pest, for which paraffin is the best cure. Put at the rate of 1 pint of paraffin to 3 gallons of water, thoroughly agitating it with a syringe for a few minutes previous to applying it, one man continuing to do this, while another man syringes the trees with the mixture. The following summer treat the trees in the same way when the leaves have fallen. As a preventive have the trees syringed every autumn with a similar mixture. Those whose Apple-trees are infested with this very injurious pest should syringe them at once with a similar mixture.

Diseased Grapes (S.).—Your Grape sample, as sent, presents a pitiable aspect. Beyond shanking, as seen in the withered stems, the berries are largely failing to mature and ripen. It is evident the root-action is at fault. Your border has, no doubt, become damp and sour, especially if, as you say, over-saturated with a leakage of water. That should be stopped. Then the surface of the border should be carefully forked off, roots lifted, the bottom soil drily broken up, and have wood-ashes and lime refuse freely worked into it; then the roots relaid, using about them some fresh soil, and adding lime-rubbish or wood-ashes to the top soil.

VEGETABLES.

Forcing Seakale (Mama).—You ought to have put some of the crowns into a large pot or box. If in pots you should invert another of the same size over the one in which the roots are planted. You should have then placed in a temperature of from 55 degs. to 60 degs. to 11 in hours they should be deep enough for the roots to stand upright, and there should be sufficient depth for the roots to grow to its full length before it reaches the lid of the box. Keep up a succession by introducing into heat a few crowns as may be necessary.

Seed Potatoes (Subscriber, Kerry).—As you do not say how many Potatoes for seed you obtained for 1s. 3d., we are unable to judge whether your price was high or low. But few seedmen could select all tubers of one size unless an extra price was paid for the sample. They have to purchase their stocks from the growers just as lifted, and they must sell. Your best course will be to set all the tubers in boxes, as you proposed, keep them in ample light and air, but from frost during the winter; then when planting time comes, cut the large tubers into about 3-ounce pieces. Lay those out thinly, and well dust with slaked lime to dry off the cut surface. Do that two days before planting. As to the very small and put two together. Of course, they are really too small for good seed, but if you need not be wasted. Puritan Potatoes should be planted in rows 2½ feet apart, and 12 inches apart in the rows. Some Potatoes give relatively few small tubers for seed, the general stock being of large size.

Application of gas-lime (Gynno).—Gas-lime is not a manure. It acts as a swardener or purifier of sour soil; it kills moulds of fungus, such, for instance, as produces club in Cabbages; and it destroys grub, wireworm, and other insect life. If you think insects, grubs, or eggs are wintering in the soil about your fruit-trees, a dressing of the lime, 1 lb. to the square yard, well broken up and allowed to lie two or three weeks before being forked in, may do good. But as your trees have been recently root-pruned, allowed in May with a coating of half-decayed manure as a summer mulch and to wash in. You can apply gas-lime at once to any vacant ground. If it is sour or needs some agency to destroy lungoid or insect life. If not, then it will do no good. A proper dressing is at the rate of 2 bushels to 3 rods of ground, allowed to lie for a month, well pulverised, then dug in. It does not help poor ground, which would be helped by a manure dressing. Apply superphosphate and kainit (potash), and dig it in, at the rate of 6 lb. per rod, in January, and 3 lb. per rod of sulphate ammonia after the crop has made partial growth.

SHORT REPLIES.

Maldstone.—1. You had better wait until the trees get established. 2. The two stocks are one and the same thing. The Doucin, however, has somewhat darker wood. —R. G. Stone.—Kindly give us the size of your garden, and also the nature of the soil, and then we can better advise you. —Acad.—Leave your Roses alone till March, and let them ripen as you suggest. —J. S. H.—In such a position you cannot get any flowering plant to succeed, as the wood will never be ripened sufficiently. The only plants you can use are some of the strong-growing trees,

which you must fasten to the wall to start them, or Ampelopsis Veitchi, which is self-clinging.—A. J. O.—See reply to "W. J." re "Replanting viney," p. 530.

M. A. H.—The *Desfontainia* is not grafted on the Privet. This plant will not grow away from the warmer sea-shore gardens. If you could send us a piece of each plant, then we would be better able to help you.—E. O. B.—See next dealing with the subject in our issue of Nov. 23, p. 512.

P. M.—Merely cut off the flowers and stand on a shelf in the greenhouse for the winter, increasing by cuttings in the spring, and potting on those you already have.—H. H. Birch.—Wait in both cases till the spring. Plant out your *Chrysanthemum* early in May.—E. Rains.—See reply to your query, which was answered in our issue of Oct. 4, p. 418.

Miz.—There is no weed-killer that you can use. See that the weeds are cut off below the collar, and then top-dress the lawn with some rich soil to help the Grass.—*Nottingham.*—Very difficult to assign any reason without further particulars as to soil, etc.—F. S. Brown.—Today's "Villa Gardening," from this office, post free for 6s. 6d.—E. H. Smart.—Plant the *Gladiolus* and *Hyacinthus* candidates at the end of next March or early in April, and get in the others at once. Leave the *Hyacinthus* in the ground. They will all do in any good garden soil.—*Prior.*—Plant out your early-flowering *Chrysanthemum* early in May. You will find a list of the best sorts in our issue of Oct. 18, p. 423.

Mrs. sooner you can plant your *Roses* the better.—P. L. Benson.—We hope to deal with the best kinds in a coming issue.—*Dainton.*—You will find a note as to relaying Box in our issue of Oct. 11, p. 425.

NAMES OF PLANTS AND FRUITS.

*. Any communications respecting plants or fruits sent to names should always accompany the parcel, which should be addressed to the EDITOR of GARDENING ILLUSTRATED, 17, FURNIVAL-STREET, HOLBORN, LONDON, E.C. A number should also be firmly affixed to each specimen of flowers or fruit sent for naming. No more than four kinds of fruits or flowers for naming should be sent at one time.

Names of plants.—*Red Lily.*—Your plant is the Snake-plant (*Arum Dracunculoides*), from South America. You cannot change the plant in any way.—*Anous.*—1, *Adiantum gracillimum*; 2, *A. Farleyense*; 3, *Hydrothamnium elegans*.—R. C. C.—*Variiegated New Zealand Flax* (*Phormium tenax variegatum*).—J. M.—*Impatiens Nilitai*. The house is too cold, as this Balsam wants a stove. Keep it in the stove and propagate from cuttings next spring.—*Bury.*—*Salvia Heeri*.—*Philip.*—One of the many forms of the Crown Aneone (*A. coronaria*).—G. Jotcs.—1, *Aconitum*; 2, *Abutilon*; 3, *Aurone* of the common Oak; 4, *Adiantum Capillus-Veneris*.—E. S. W.—*Aster cordifolius elegans*.—*Maise.*—1, *Aparagus decumbens*, easily increased by division in the spring; 2, *Centaurea ragusina*.

Names of fruits.—T. *Burroughes.*—1, Hunt, Lane's Prince Albert; 2, Cripp, Yorkshire Greening.—*Alfred Salt.*—1, Three fruits sent to be small Emperor Alexander, the other two are different; 2, Rymer, M. M. Everard, 1, Yorkshire Greening; 2, *Yorkshire Seedling*; 3, *Spencer*, insufficient; 4, *Waltham Abbey Seedling*. As we have so often said, it is very difficult to name fruit when only one specimen is sent. See our rules.—E. C. T.—*Duchesse d'Angouleme*.—*Hertfordshire.*—1, Winter Hawthornden; 2, Not recognised.—H. K. A.—1, Red Hawthornden; 2, *Beauty of Hants*.—*Hope K. Birke.*—1 and 2, Not recognised; 3, Autumn Pearmain; 4, Small Mere de Menage. It is very difficult to determine names when only one specimen of each is sent.

Catalogues received.—Wood and Ingram, Hinton-Ington.—*Special Revised Catalogue of Nursery Stock.*—The Horticultural Company, 1, Beale-Hill, Cheshire.—*List of Seeds and Plants for 1903.*—F. Bower, Quedlinburg.—*Special Trade Offer of Extra Choice Flower Seeds and Nurseries for 1903.*

Request to readers of "Gardening."—*Readers, both amateur and in the trade, will kindly remember that we are always very glad to see interesting specimens of plants or flowers to illustrate, if they will kindly send them to our office in as good a state as possible.*

CHILDREN'S PARTIES

are a delight to the young folk, and a source of anxious thought to the Mother. But the Maternal mind may be relieved of much anxiety if *Chivers' Table Jellies* are expressly ordered for the feast. They are pure and wholesome, and are flavoured with ripe Fruit-Juices. Dr. Andrew Wilson, an authority on foods, says: "Chivers' Jellies cannot be surpassed." Your Grocer stocks them in various flavours in pints and quarts. Cambridge Lemonade is a safe and welcome beverage after romping. "It beats all." Chivers and Son, Limited, Histon, Cambridge. First English Fruit Growers' Jam Factory.

HYACINTHUS, 6s. 6d., 10s. 6d., 15s. Tulips, 1s. 9d., 2s. 6d., 3s. 6d. Daffodils or Narcissus, 1s. 9d., 2s. 6d., 3s. per 100. Crocus, 2s. 6d. per 100. 4s. 6d. 7s. 6d. per 1000. See orders card, post. Catalogue free.—W. PERRY, 5, Brickhill-lane, Upper Thames-street, London.

WALLFLOWERS, large, 5 best named sorts, 1s. 6d. 100. Herbaceous plants, 12 named sorts, 1s. 3d. Bed Cabbages, 8s. 6d. 100. All post free.—D. BOXHEDGE, Boxhedge Farm, Banbury.

CHEAP LOTS.—9 Car. Salamander, 1s.; 6 Car. White Glove, 1s.; 6 Car. Crimson Clove, 1s.; 6 Car. Ruby Castle, 1s.; 9 Pink Albino, 1s.; 10 Pink Mr. George, 1s.; 9 Pink Sam Barlow, 1s.; 12 White Phloxes, 1s.; 50 Spanish Iris, 1s.; 6 Pink Paddington, 1s.; 12 St. Bridget Anemones, 1s.; 12 Blue Delphiniums, 1s. 6d. Tulips, 1s. 6d. per 100. See all our list.—J. LANGFORD, The Nurseries, Wintonham, Manchester.

POLYANTHA ROSES.—Clusters of lovely flowers in spring, the following beautiful varieties: Cecile Brunner, Marie Fautie, Perle de Roques, Gloire de Polyantha, l'acquerette, Mignonette, White Pet, and Melanthe. The 6 varieties, strong plants, 4s. 6d. for 2s. 6d. per 100. FOX, Floral Nurseries, Bakersby.

ROSES, SHRUBS, PALMS, AZALEAS.

The following I have to offer are simply splendid value. Order at once, get the best. Grand time for planting.—*Dwarf Roses.* 11 L., strong and bushy, true to name, 6d. each; 2s. 6d. Tea, such as Liberty, Fairy Ruby Gold, Sunrise, The Bride, Ideal, Niphetos, Bère d'Or, Grace Darling, many others, 1s. each; 5s. doz. Turners' Crimson Rambler, the trees, 1s. each; ditto, 5 to 6 feet high, very bushy, 1s. 6d. each. Pink Ramblers, novelty, fine trees, 1s. 2s. each. Lovely White Rambler, 1s. 2d. each. Latest novelty, "The Yellow Rambler," grand trees, 1s. 3d. each. W. A. Richardson, Marchal Niel, Niphetos, Gloire de Dijon, La Reine, and other splendid Climbing Roses, fine strong trees (whall) only 1s. each; worth 3s. 6d. Standard Roses, all leading kinds, grand heads, 1s. 6d. each. Gooseberry Trees, 4 years old, good fruiter, all to name, 4s. 6d. doz. Currants, Red, White, or Black, 4 years-old bushes, 2s. 6d. doz. Priset oralfatum, 2 to 4 feet, 6s. 100. Ribes, or Flowering Currants, grand for hedges, 6d. each. American Blackberry, 4d. each. Guelter Roses, 6d. doz. 3d. each. Fancy Shrubs, for pots or windows, 6d. each; 4s. doz. Bay, sweet, Rose large plants, 1s. each; smaller, 6d. each. Cherry, double bloom, 1s. each. Double Pink or Red May, grand bushes, 1s. 3d. each. Clematis montana, 4d. each. Yellow Clematis, novelty, 4d. each. White scented Clematis, 2d. each. Blue Clematis, fast climbing, 3d. each. White and Red Lilacs, fine trees, 3f. and 6f. each. Double Scarlet Lilac, 1s. each. Maiden Hair Fern Trees, very hardy, 4d. each. Ampelopsis Veitchi, self-climbing, 4d. each. Deutzias, fine bushy plants, 4d. each. Ivy, Irish, 2d. each. Magnolia grandiflora, fine plants, 1s. each; small plants, 6d. each. Ampelopsis Veitchi, in large pots, well trained, 3d. and 1s. each. Clematis, all named sorts, in pots, 1s. each. Money tree, 4 to 6 feet high, 6d. each. Acazia Trees, 3d. each. Lavender Trees, very bushy, 3d. and 5d. each. Honey-suckle, in splendid sorts, 4d. each. Laburnum Trees, 3 years old, 4d. each. Jessamine, white and yellow, 3-year-old plants, 4d. each. Tulip Trees, 4d. each. Mock Orange, fine trees, 4d. each. Spruce Trees, 4d. each. Southernwood, or Old Man, 3d. each. Sweet Briar, strong plants, 3d. each. Wistaria sinensis, 6d. each. Camellia Trees, well set with bud, 1s. 6d. each. Xmas Roses, full bloom, 3d. each, sold thousands last year. Rosemary, bushy trees, 2d. each. Hydrangeas, Thomas Hees, fine plants, 6d. and 8d. each; smaller, 4d. each. 1800 fine large bushy Rhododendrons, in many colours, well set with bud, good stuff, 6d. and 8d. each. 6,000 Azalea Indica, for greenhouse, splendid stuff, select plants, full bud, 1s. 6d. each; 3 for 4s.; or extra bushy plants, very large, 2s. each; 6 for 10s.; these are a marvel. 70,000 Palms, all fine, elegant, healthy stuff (this is a chance seldom met with), 3d. 6d., 9d., 1s., 1s. 6d., 2s., 2s. 6d., 3s. each. These Palms are a marvel; must plant, none wasted. 10,000 Ferns elastic, or India-rubber plants, grand for table or hall, grand plants, 9d., 1s., and 1s. 6d. each. 50,000 Fancy Ferns, for pots and baskets, 8s. 1s. Place an order. I am sure we shall please you. All orders carefully packed, packages free. All orders from 10s. upwards carriage paid by rail address.

PLANTS AND FLOWERS.

CHRYSANTHEMUMS.

LARGE CHRYSANTHEMUMS.

TO THE EDITOR OF "GARDENING ILLUSTRATED."

SIR,—A good many of your readers will, I think, agree with Mr. Millington in his criticism of Chrysanthemum shows, in spite of the protest it raised last week. I have before me now a batch of catalogues of new varieties. Almost all belong to the Japanese class. "Immense bloom," "very large flower," "a monster," "very popular, being a large flower," "9 inches across," "large, handsome flower," and "white, rivaling Mme. Carot in size," are descriptions of the high-priced novelties. Every amateur knows full well from past experience how miserably so many of these will fail to please when he grows them—how he will turn with disgust from looking upon their two or three lanky stems and their, as likely as not, coarse, uninteresting blooms 3 feet and more above the pot, to rest his eyes upon the profusion of Petite Amie, Phidius, Framfield Beauty, Purity, and Mary Anderson that have not been grown for the shows. Growers raise to sell; they sell to live. They must raise what exhibitors, who are their best customers, know the shows require of them. Effort in every direction but in the race for big Japanese blooms is discouraged by the practice of the shows. Colour and form are sacrificed on the altar of size. Let me illustrate what I mean by a reference to the November Aquarium Show. Among the multitudes of Japanese blooms there was not one good crimson to be seen. Though yellows were staged by the score there was not a shade among them we had not been accustomed to for years. The eye was wearied with the monotony. I recollect well seeing Hooper Pearson for the first time at the Aquarium a few years since. It stood in the trade exhibit of a prominent raiser. To judge by the remarks of the visitors it was one of the delights of the show. At the recent exhibition it was represented by, I believe, one bloom. Exhibitors cannot afford to grow it, it lacks the all-important qualification of size. One might multiply illustrations from the Japanese class of this stiling of effort towards development of colour and form by the practice of the shows.

To pass to the Anemones. Is it not, to put it mildly, a matter for regret that the committee of the premier show of the world should give no encouragement to the development of these exquisite flowers? They can lavish money upon their big Japanese, but for the Anemones they can offer but a paltry sum, with the result that the exhibit in this class is gradually becoming insignificant, and progress is at a standstill. Much the same may be said of the singles. The exhibit in this class was very disappointing. Those who grow them in quantity will bear me out that they offer many possibilities for an effective display. The Aquarium could not avail themselves of any of them. The exhibit was a sorry and

was the qualification for the prize. I visited the small hall late in the day. There in "dim religious light" the specimens in pots were shown. If anywhere, it is in this class some attempt might be made to encourage the love of the beautiful. And what was the show? A collection of antiquated varieties tied and staked to look as unnatural as possible—as unlike the things of beauty pot-plants should be, as skill and ingenuity could make them. But these monstrosities were awarded the prizes. It was a flower show, and one felt a relief to turn to the Carrots and Onions.

There are signs that Chrysanthemum societies are passing through a period of financial difficulties, and this is not to be wondered at. The public are a little satiated with the monotony of the shows. People want to see more change in these annual displays. People who love the beautiful in nature want evidence of taste. People who care for none of these things want a little more variety for their shillings. The Chrysanthemum is without a rival among our cultivated plants; the possibilities it holds out to the raiser who will but study it seriously are endless. He can give us for our conservatoria dwarf plants covered with bloom. He can give us for our tables cut-flowers that will charm the eye with colour and form. He can give us for our shows such a display as will rival the gardens of summer for variety. He can, but he does not. He is bound down to the routine of the Medes and Persians of our societies. C. A. GRIFF.

CHRYSANTHEMUMS—NEW EARLY-FLOWERING VARIETIES.

(REPLY TO "NOVEMBER.")

SEVERAL of the varieties mentioned in your list can scarcely be regarded as early varieties, and the list herewith embraces the best of those added to the early-flowering section during the last two seasons. We have given a preference to varieties which are free-flowering and also branching in their style of growth, although by so doing we may be including some varieties known to develop rather larger flowers than the majority of sorts.

HURACE MARTIN.—This, a sport from the well-known Mme. Marie Masse, is rich yellow in colour. In growth the plant is ideal, and also free-flowering. Each flower having a long flower-stalk adds very materially to its value. Height 3 feet; in flower from August till October.

RYECROFT PINK.—The colour of this is a beautiful and telling shade of bright pink. It is of sturdy habit, height about 2 feet. Period of flowering mid-September to mid-October.

LEONARD PÉTO.—But for the appearance of Horece Martin, this variety would have elicited the highest praise. As, however, it is quite distinct from the variety just referred to, its inclusion in this list is justified. The colour is a clear, bright, and effective yellow, and the habit is very bushy, and the flowers are developed in the greatest profusion. Height 3 feet, in flower during September and early October.

ROSE YVON.—This, one of the newer sorts,

develops charming blossoms of a pleasing shade of flesh-pink, and is a welcome break from the lilac and mauve shades of colour which at one time prevailed. The flowers may be regarded as pure self-coloured. Height about 2 feet. Period of flowering September and later.

GOACHER'S CRIMSON.—This variety should be grown for its colour, which is rich, bright crimson, with a golden-bronze reverse. The flowers are large, and each one is borne on a long, stout, erect footstalk, which should add materially to their value, either for cutting or for border culture. Height not so branching as in most others, yet distinctly good. Height about 3 feet. In flower September and October.

CHATEAU ST. VICTOR.—This variety is not so much a novelty as are the others described here. The colour is a bright amaranth, and the plant, which has a nice bushy habit and is about 3 feet 6 inches in height, makes a fine display throughout September and early October.

ORANGE MANSE.—Although not quite so early-flowering as one could wish, this makes a very large and handsome bush, and is literally covered with charming flowers of a rich apricot colour, tipped orange. When grown without disbudbing from terminal buds, the sprays of bloom are invaluable for decoration. Height 4 feet. Period of flowering October. The name may lead some growers to suppose this variety is a sport from Mme. Marie Masse or its sports, but this is not the case. Naming the plant in this way is very misleading.

DORIS PÉTO.—A distinct gain to the pure white early kinds. This plant develops flowers equal in form to those of Mychett White, and in so far as regards constitution is quite on a par with Market White, which has always been highly thought of in this respect. Throughout September and October this plant, which is less than 3 feet high, is seen at its best.

NORBERT PROKEZ.—Although introduced about twelve years ago, this variety must still be looked upon as a novelty. The plant was first sight of for many years, and has only recently been found again. Truly it is a beautiful flower, the colour being a rich golden-salmon, and the blooms are large. Height just under 3 feet. In flower late September and October.

CRIMSON MARIE MANSE.—This is another sport from Mme. Marie Masse, and the colour when the blooms are first opened is a fine chestnut. As the flowers age they pass to a deep bronze colour. In every other respect the plant is identical with the parent variety.

IRENE HUNT.—This plant bears a profusion of lovely chestnut and gold blossoms, having rather long and twisted florets. To be seen at its best this plant should be slightly disbudded. Height about 3½ feet. In flower September.

Mons. Louis LINNET.—Another one of the older sorts, which may still be looked upon as a novelty. The bushy plant bears a profusion of charming blossoms of a flesh-pink colour. Height 3 feet. Period of flowering September.

C. A. G.

Chrysanthemums with an open centre (*J. R. H.*).—Your experience is quite common with beginners, and need not discourage you in the least. Several reasons could be given why the blooms of your Chrysanthemums have failed to develop. One of the chief reasons why Chrysanthemum blooms open with an eye is want of good culture, and this is why so many novices fail in this particular. A beginner cannot be expected to know much during his first season as a cultivator, but practical experience, supplemented by information gathered from journals devoted to gardening, generally will give indefinitely better results in the second season. Your plants very probably are Japanese varieties of somewhat difficult culture, and to succeed with plants of this description, a long season of steady growth is absolutely essential. For this reason, therefore, commence to propagate by inserting nice healthy cuttings as soon as they can be obtained. The earliest days of December should answer your purpose admirably. First procure some good loam of somewhat light texture, and equally good decayed leaf soil. Take of these

ROSES.

OLD-FASHIONED CLIMBING ROSES.

KINDLY give me a list of the real old-fashioned Roses Cluster and others, which are now becoming rare?—*MADAME LAGONIER.*

[Now-a-days it is all the rage to plant Rambler Roses, but who would not desire some of the old Noisettes which give us of their beauty in the late autumn as well as in June? Growers for sale find it almost impossible to maintain large collections of Roses, for it does not pay to grow what does not sell. Therefore, it would appear that we are in danger of losing many old Roses if these Ramblers are to take their place. It is true some of the best of the old favourites are still to be obtained, for instance, the delightful Aimé Vibert, which will give its snowy blossoms even in November. But how we miss such as Desprez à fleurs jaune, a beautiful mixture of red, buff and yellow, and as hardy and sweet as it is good. Lamarque, being somewhat tender, is perhaps overshadowed by Mme. Alfred Carrière, but the latter, splendid as it is, does not compare with Lamarque in

raised by Ducher in 1879, and if it is not identical with Cooling's Yellow Noisette, it certainly bears a very close resemblance to it. Many other old Noisettes I can recall, such as Caroline Furniess, Jeanne d'Arc, La Biète, Mme. Massot, Miss Glegg, Triomphe de Rennes, etc., all of which seem to be fast disappearing. The last is really too good to lose, but it is capricious, and is, perhaps, more fitted for greenhouse culture than outdoors. I am sorry to see these old Roses disappearing, for they made the walls bright with blossom in the autumn months when so many individuals are at their country homes. It is true we have a host of Teas and Noisettes to take their place, but they somehow lack the profuse blossoming of these older Noisettes. Before I leave the Teas and Noisettes I would remind planters that they need not fear being able to obtain some really good wall Roses in the recent additions to these groups, and although one is rather loth to lose old acquaintances, yet if there are others that are improvements, then we should be thankful for them. All who plant such as Climbing Kaiserin Augustus Victoria, Billiard and Barré, Noëlle Nabou-

Root of Giant Lily (*L. giganteum*), showing the offsets.

two soils equal proportions, and pass through a sieve having a $\frac{1}{4}$ -inch mesh. Add very liberally coarse silver sand, and mix the whole heap in a thorough manner. Use thumb-pots, and insert the cuttings singly in these, pressing the soil firmly around the base of each cutting. Stand the pots in a frame or glass-covered box, watering in the cuttings previously. The small frame or box should be stood on the greenhouse bench, and the temperature kept at about 45 degs. When rooted, remove the young plants to the greenhouse shelf and keep them growing sturdily. Repot as needed, and give the plants hardy and consistent treatment until housing time in the autumn.

Chrysanthemum Dorothy Pywell.

—This is a refined and handsome Japanese bloom, and is quite free from that coarseness which characterises some of the newer introductions. I recently saw about 150 plants of this superb variety, each plant carrying three or four large and handsome blooms. The colour may be described as ivory white, and the florets, which are long and fairly broad, build up a bloom of considerable depth. The height of this plant is about 6 feet. Any amateur can grow the plant well.—*E. C.*

shapeliness of bud. Solferino, when given a sunny wall, is not only most rampant in growth but flowers freely. Ophirio is certainly not to be compared with William Allen Richardson, but yet it ought to have a place for its reddish copper-coloured quaintly-formed blossoms. Earl of Eldon was a good wall Rose, and in its day considered of great merit. Even within the last ten years this Rose has, by crossing, given us a very beautiful variety named Beaute Inconstante, for I am informed by M. Pernet-Ducher that he was fortunate enough to cross a seedling of Earl of Eldon and Mme. Falcot, which resulted as I have already pointed out. That Beaute Inconstante will play a conspicuous part in stamping its unique colouring upon many future novelties seems very certain. Fortune's Yellow, sometimes known as Beauty of Glazenwood, has certainly been saved from oblivion by some few individuals, who have planted this fine Rose under glass and exhibited its blossoms at the spring shows. It is without doubt one of the most remarkable climbers we possess, but must have a dry, sunny position, preferably under glass. We often find an old Rose resemble a new comer. I have one in mind now. I refer to Joseph Bernachi-

and, Fanny Stolwerek, Mme. Jules Siegfried, Francoise Crousse, the last a very brilliant Rose and highly commended, Dr. Rouges, etc., will not regret so doing.

We used to grow a grand Rose, named Belle de Bordeaux. If it was somewhat deficient in brightness, it was extremely hardy. Another excellent half climber was Sombriuel. Of course, this is still obtainable, and I would commend it for its snowy blossoms, which are freely produced in autumn. Unless it be for lofty walls I think we miss a grand opportunity in not planting the strong-growing Tea Roses usually grouped with the dwarf section. I refer to Marie Van Houtte, Anna Ollivier, and such like, not forgetting Souvenir d'un Ami, of which Dean Holo says he once had on a wall a specimen 7 feet high, in which a thrush built her nest.

Perhaps I may be allowed to refer to one or two really good old climbers that every one should make an attempt to obtain. First, there is the old Double Yellow or Yellow Provence. I know there are readers of GARDENING who succeed well with this erratic Rose. I wish they would tell us how they manage it. I have seen the specimen at Burghley House, and the late Mr. Gilbert even gave me some

buds. but beyond the first year I could not succeed with it. Is it a chalky soil this Rose requires? It is such a wonderful yellow that it is worth trying to grow even if failure follows. Can Blairii No. 2, the common Blush China, the old Crimson China, and others of this class be surpassed when treated well?

and not to be compared with the lovely violet-scented double white. Old Roses worth retaining are Bourbon Cadicalle, and also Gloire des Rosomanes. Finally, I would commend La France de '89 to all who desire a large, profuse blooming Rose for moderate wall. This Rose, although not old, is gaining favour in spite of its name. When looked up to, its huge blossoms appear like so many rosy-crimson Paonies.—ROSA.]

Rose La France late in November in Notts.—I beg to forward photograph of a bed of La France taken last Friday. As a proof of the mild weather, I thought you might find it of interest.—J. BRYKOWSKI HOLZ, Nov. 27, 1902. [The blooms shown are well formed and numerous.—Ed.]

OUTDOOR PLANTS.

LILIUM GIGANTEUM.

A COLONY of this Lily, with six or more bulbs in flower, as in our illustration, forms as stately and unique a garden picture as can be conceived. Such a display, however, must not be looked for during the first season or two after planting; but when the bulbs are well established and throwing up their lofty flower-spikes, the grower is amply repaid for waiting. The bed should be formed, by choice, in a sheltered situation, where deciduous trees, at a little distance, throw a partial shade and intercept rough winds, and should be fully 3 feet in depth. Decayed vegetable matter and fibrous loam form the most desirable compost, while an annual top-dressing of well-rotted hot-bed manure and leaf-mould adds to the vigour of the plants. If so-called "flowering" bulbs are procured, and they happen to bloom the year after planting, their flower spikes rarely exceed from 4 feet to 6 feet in height; whereas,

if, as is most probable, their blooming season is delayed, they attain a far greater stature, often exceeding 10 feet or 11 feet in height. In purchasing bulbs for such a bed as described it is well to refrain from procuring those of the largest size, for the reason set forth above. From one to two dozen small to medium-sized bulbs will produce a grand effect when fully established,

as they will be before they throw up their flower-spikes. The flowering bulbs when they die, as they invariably do after blossoming, will be found to have produced offsets (see illustration on opposite page), which, if lifted and replanted, will, in the course of four years or so, themselves bloom, and the bed, being thus filled with bulbs of varying size, will annually contain flowering specimens.

Lilium giganteum is seen in but few gardens, and, in those in which it occurs, it is often represented by but one or two flowering plants, the effect of which is not to be compared to that produced by half-a-dozen or more stately flower-spikes, ranging from 8 feet to 10 feet in height, standing in close proximity. The long, ivory-white blossoms, stained with purple in the interior, ten to twenty of which are often borne on a single flower-head, emit a delicious vanilla perfume.

RAISING FROM SEED.—Our experience with the seed of Lilium giganteum is that not more than 10 per cent., and frequently less, can be expected to germinate, and, when one

considers the large quantity yielded by a single plant, this represents a goodly number. The seeds may be sown in pans in a mixture of loam, peat, and sand. They should be covered with about a quarter of an inch of fino soil, and placed in the greenhouse or in a garden frame. Bottom-heat is not at all necessary for them; in fact, they are better without it, as it tends to weaken the young plants. The seed may be expected to germinate in the spring, and when the seedlings are large enough to handle they should be pricked off into other pans or boxes, using the same kind of soil. The following season they can be planted out in a sheltered spot, and care must be taken that they do not suffer from drought during the summer. In the raising of this Lily from seeds a considerable amount of patience is necessary, as the young plants will take seven or eight years to attain flowering size.

THE BELLADONNA LILY (AMARYLLIS BELLADONNA).

THIS may not be a success too far north, but where it does succeed it is most useful from the early part of September to well nigh the end of October. Owing to the precarious summer I was unable to cut until the middle of the former month this year, while in some seasons flowers have been ready by the first Monday in August. Even in the west the warmest position must be chosen for it, and where the bulbs can be planted within 6 inches of a wall and no roots of tree or even shrubs to trespass anywhere near, and the aspect pretty much south, I find them most satisfactory. It resents too much interference with, and will go on for several years with very little aid in the way of manure or fresh soil, though no doubt could a little loam and bone-meal be given each year better results would follow. In my case, a row of Anemones is planted about 6 inches in front of the Belladonna, so that unless the latter shows signs of deteriorating no assistance

Lilium giganteum in an Irish garden. From a photograph by Miss Sophie M. Wallace, Ardnamore, Lough Eske, Co. Donegal.

Some of the old-fashioned Hybrid Chinese, such as Charles Lawson, Coupe d'Hebe, &c., hardly come under our review, as they are really pillar Roses. Albeit, they are splendid for wooden fences, where good, hardy kinds are desired. But here, again, the H.P.'s have superseded them for even this purpose.

I do not imagine there is any danger of the Ayrshire and Sempervirens Roses falling into oblivion. I find them as much sought after to-day as ever they were. Of course I do not mean all the kinds. Among these tribes there are several that resemble each other too closely. It is not collections we want but selections. So that if we plant Raga, Dundee Rambler, Bennet's Seedling, Alice Gray, and Queen of the Belgians, we have as many of the first-named tribe as can possibly be required, and Felicité-Perpetue, Flora, and Myriantbes renoncule are the best of the Sempervirens group.

Of the Multiflora group, the Seven Sisters seems to be difficult to obtain. I believe the De la Grifferaie is as near as possible a replica of this old Rose. Lanré Davoust is pretty, but surpassed by Euphrosyno. Mme. d'Arblay is very rampant, and altogether a good Rose for wild garden or pillar. The Prairie Roses are not in much request in this country, neither do I think we miss anything by their absence. The Banksian Roses, white and yellow, are still popular, but require to be either planted under glass or given a warm wall. Planters should be on the alert against a spurious thorny wooded kind often sold for the white Banksian. It is really Fortuniana,

Part of group of Lilium giganteum. From a photograph sent by Mrs. H. Peters, Bill Hill, Wokingham.

in the form of fresh soil is afforded. Where it is considered necessary, early in the month of December I find is a good time to assist them just as new growth commences, and if thought necessary to take them up and plant them in the same soil as soon as they

pass out of flower. Anemones were planted in front to flower early, which they do, especially fulgens, when very little foliage has been made by the Belladonna, but later in the spring it smothered the former, and, of course, to its disadvantage, as it cannot ripen properly, though it blooms better than one would expect under such adverse circumstances. Another good plant to put in front of the Belladonnas is *Zephyranthes candida* (the Peruvian Swamp Lily), recently figured in these pages. The flowers are pure white, borne singly, and at their best early in September. I planted it in this position on account of its Grass-like foliage, which to some extent compensates for the absence of the Belladonna foliage, which is its only drawback when grown in any prominent position. When the foliage begins to fall in early summer it should be allowed to ripen off thoroughly before removing it.

In arranging the spikes a little foliage of *Clivia* sets off the flowers nicely if about a dozen are set up in a large vase. During summer, when in growth and the weather hot and dry, frequent waterings should be given, and again as soon as the spikes begin to push up, as it is often dusty at the foot of a south wall, even should rain fall every week or so. If the bulbs have been several years planted, a little weak manure-water occasionally would prove beneficial. Of late years an improved form of this noble Lily has cropped up, which intending planters would do well to secure.

EAST DEVON.

HERBACEOUS LOBELIAS.

EXCEPT in a few favoured districts these Lobelias will not survive our winters outdoors, and must be lifted and stored in a greenhouse until the return of spring, when they may again be placed where required to blossom. If not already lifted, the matter should be no longer delayed, and a convenient way of doing it is to place the roots, after relieving them of surplus soil, close together in boxes, filling in the interstices with light compost afterwards, giving the boxes a shake now and again to make sure there are no hollow spaces left. An excellent place to keep them through the winter is on an airy shelf in a cold greenhouse. Here they will keep in capital condition and free from their greatest enemy, damp, and in spring they can be split up, if it is desired to increase the stock, or they may remain intact till planting time arrives. The greatest favourites are *L. cardinalis*, *L. c. Firefly*, and *L. fulgens* Queen Victoria, a distinguishing feature of the last being its glossy deep bronze foliage. *L. Queen Victoria* has brilliant vermilion flowers, and grows to a height of from 3 feet to 4 feet. The colour of the flowers of the first two named sorts is bright scarlet, and they grow to the same height. There are also several other varieties, such as *L. f. Gerardii*, rosy-violet; *L. f. Rivoirei*, rosy-scarlet; *L. sylvatica*, pale blue. Among the newer varieties deserving of mention are *Carmine Gem*, bright carmine; *Distinction*, crimson, shaded with purple; *Jupiter*, rose-purple; and *Lord Ardilaun*, crimson-scarlet.

Established plants may be bought, or a stock can be raised from seed of the better known and more popular sorts, which should be sown in heat early in the new year. These seedlings make nice plants and flower the first year, but it is in the second season that the plants make a full display and attain their proper height. Mixed with the white Japanese Anemone in a bed, or planted in clumps of nine to twelve midway between the back and front of herbaceous borders, they create a brilliant and dazzling effect, and flower at a time when this particular colour is none too plentiful.

A. W.

THE MIXED BORDER BEAUTIFUL.

TO THE EDITOR OF "GARDENING ILLUSTRATED."

SIR,—The letter of "L. D. L.," in your issue of Nov. 29, very strongly commends itself to me, and the writer has my sympathy. I, too, am a lover of the mixed border beautiful, but the numerous paragraphs I have met with, advocating "colour schemes," have had as depressing an effect upon me as constant blotches of one colour in the same spot in a border would have.

I think them right. I have some fairly large beds in Grass, which in spring are delightful with the rich gold of *Forsythia suspansa*, the bright reds and pinks of *Ribes sanguineum* and *Cydonias*, which later give place to glorious groups of white Madonna Lilies, and I find the change altogether charming. Then, again, with a large group of various Brooms—white, yellow, etc.—when their blooming is over, the bed glows with Tiger Lilies, and, later still, is aflame with Tritomas. I have also a large herbaceous border which is edged with Daffodils, Mrs. Sinkins Pink, and Montbretias. In spring this edging is gay throughout its entire length with the yellow of the Daffodils; later, I get the fragrant white of countless Pinks, and, later still, the orange-red and yellow of the Montbretias.

I have not striven for the "constant colour scheme," yet I find few jarring notes between either of these edgings and the varied colours of the larger plants deeper in the border. I may be wrong, but it seems to me the effects I get are the lovelier because my colours move about, so to speak. Nothing would weary me more than to look from my windows and always see the same splash of colour in one spot. The gorgeous colourings of my Azalea beds are no whit less beautiful because they are followed by the white of *Lilium longiflorum*; *L. speciosum* Kratzeri, etc., and, later still, by the purple of the *Menziesia polifolia* edgings. The flowers of the field grow where they may, and who is so bold as to say such natural grouping is wrong?

I think if we paid more attention to the artistic grouping of flowers and flowering shrubs in fine form, without the endless striving for one range of colour in one spot throughout a season, gardeners would do better. Of course, no one with an atom of taste would argue that such violent contrasts as brilliant blues and vivid scarlets planted together are correct or agreeable, but there is a medium course, and the wise man will strive to follow it. One may do worse than take a few ideas from the skies, and emulate them in their ever-varying colour effects.

B. W. A.

NOTES AND REPLIES.

Carnations failing.—Finding border Carnations went off badly last winter, I am anxious to make another start. The soil is a medium loam. Would a good dressing of marl or clay improve it? I mean to follow the bed this winter and plant in the spring.—H. M. P.

[Your best plan will be to have the border trenched, adding as the work goes on a liberal dressing of well-rotted manure, a little mortar rubbish, and some road-scrappings. A little bone-dust may be added at the same time. Perhaps the cause of the plants going off was wireworm. If this be the case you ought to dress the ground with gas-liquid.]

Top-dressing lawn.—Would dressing advised for golf-green answer for lawn, in issue of Nov. 29, p. 518? The lawn is in fair condition now, and has previously, I am told, been dressed with horse manure. It is not very fine Grass, and here and there wiry, coarse stems make rampant growth, as do Dandelions. One part, where, probably, soil is shallow, gets brown in summer. Would cow-manure do good on this part.—M. SMITH.

[You ought to dig out the rough Grass and also the Dandelions, filling up the spaces with fine soil. Then top-dress the whole of the lawn with the mixture recommended for the golf green. The part which gets brown you ought to take the turf off and dig up, well incorporating some good manure and relaying the turf. Top-dress this part as well. You could in the spring lightly top-dress again and sow some good Grass-seed.]

The Barren Strawberry (*Wahlsteinia trifolia*).—This seems to succeed in almost any kind of soil and situation. It is suitable for planting at the extreme edge of herbaceous borders and in front of the rock-garden, as in such positions its bright yellow flowers are seen to the greatest advantage. The plants should be set out in groups of not less than five or seven, when they quickly spread. On a south border it comes into flower at the end of May, and ten days later on one having a western aspect. There is another variety named *W. geoides*, but the above is, in my opinion, by far the prettier of the two.—A. W.

Echeverias in winter.—These plants, frequently seen as edgings to flower-beds in summer, are not so tender as many people imagine, and anyone who has had a cold frame

under a wall sheltered from the east will be able to winter them, provided in exceptionally severe weather some little extra covering is afforded by placing mats over the lights. I often see them in greenhouses occupying places where other things perhaps more useful might be found room for. *Echeverias* do not want heat, but simply keeping from frost and damp, and for years I wintered them in cold-frames in boxes filled with sand, withholding water entirely. A cool, dry potting-shed will answer the purpose.—LEARNSTON.

The New Zealand Flax (*Phormium tenax*).—Can any of your readers inform me if they find this plant succeed with them in the open air? I have a lot of young plants that stood fully exposed through the past two winters and have grown into handsome plants. I do not suppose if they will withstand any very severe frosts, as we have not had any such to try their hardiness. From their fine, leathery leaves, one would suppose that they would stand a rather low temperature.—JAMES CLAY, Glasgow.

[In warm gardens in the south and west of England and Ireland this does very well in the open air, given a light, deep soil. The variegated variety is also pleasing in the open air in warm situations in the south of England and Ireland, and, in any case, it will do out-of-doors in the summer. There used to be a plant in the R.H.S. Gardens, Obiswick in a border against a wall facing north, which stood several winters. In the same border were also several Camellias which flowered freely every spring.]

Tree-leaves.—It is a matter for surprise that so few persons who have gardens, and especially grow pot plants or flowers in borders or beds, should not collect at this time of year leaves that have fallen from trees, as these, when in due time well decayed, form most valuable manure or potting soil. There are many opportunities to secure these leaves, where trees overhang roads. With a couple of boards, 18 inches by 6 inches each, one in each hand, and a wheelbarrow, or a box or basket on wheels, it is possible to collect, in the course of a couple of weeks, quite a large heap, making with them a square but not too deep stack. It is a good plan to mix with the leaves horse-droppings from the roads, and then, in making up the heap, to dust freely with soot and well moisten with house-slops. Also well soak the heap from time to time with this liquid. If the heap can be turned once in two months, it will greatly help it to decay.—A. D.

Watering Violets in frames in winter.—It is no uncommon thing to see a question as to watering Violets in winter in garden papers. This is more easily asked than answered, especially when no information is given as to the conditions under which they are growing. Those who frequent gardens know how varied is the culture of this favourite flower. At the close of September and early in October I visited several gardens over a wide area. In one place in Kent I found in a good garden some Melon-pits had just been filled with both double and single Violets. These pits faced south with a sharp pitch, and on asking my friend regarding the behaviour of the big-long-leaved single kinds, he said he reduced the leafage when the plants were put into the pits, and they were a great success. A few days after I saw in another well-known garden in Hampshire many garden frames filled with double kinds. These were partly filled with soil, bringing the foliage up to the glass. These were placed in the front of some vineries where the roots were inside. In both of these cases it would be advisable to water the Violets through the winter. I adopt a different treatment. I have some shallow garden frames that are used on leaf-beds for *Gloxinias*, etc., during summer. During October these are prepared by putting soil over the leaves. Towards the close of that month the plants are lifted from their summer quarters with big bells (preserving all young roots), placing them in these frames, and bringing the foliage close up to the glass. I never allow the lights to remain on the Violets till I am obliged to, this retarding them, and also keeping the leafage hard and damp-proof. This year the lights were not put on till November 12th. What makes Violets damp in many instances is shutting them up during the autumn. During the time the lights are kept off the Violet plants receive all rain, and should there be no rain through waterings are given to wet the surface of soil. During the past three

winters no water has been given them during the last six weeks of the old year and the first eight weeks in the New Year. The situation is low end damp.—J. CROOK.

WHITE CACTUS DAHLIAS.

WHITE in any flower is a colour raisers are always ambitious to obtain, and it is a shade usually the most difficult to get in conjunction with other qualities. The first really good variety was

KEYNE'S WHITE, still cultivated largely, but at best uncertain.

GREEN'S WHITE came with a great flourish. This, after a season, was discarded—at least, for exhibition. It has a free-flowering and good habit of growth, whilst the colour of the flower

National Dahlia Society, and an award of merit from the Royal Horticultural Society.

INDOOR PLANTS.

CHINESE PRIMULAS.

VERY common now at autumn flower shows are classes for both single and double Chinese Primulas. But a few days since I was interested to see at the Sutton (Surrey) show a class for seed-raised semi-doubles, and there were some half-a-dozen collections of six plants each shown. Generally, the specimens were capital, but most of the competitors exhibited one variety only, the most favoured being white and carmine. Seeing that such beautiful

been some five months in bloom. The plants are dropped into rather larger pots, fine, sharp soil put round them, then the side growths neatly notched, and layered into it. When well rooted these are cut off, potted singly, and grown on near the glass until, in either 6-inch or 7-inch pots, they in due course become superb specimens. A. D.

NOTES AND REPLIES.

Perpetual-flowering Carnations.—Please give me names and colours of twelve good Carnations to grow in pots under glass? I want perpetual-flowering sorts, or those that will give longest period of flowering, and prolific bloomers. How old will the plants be before they commence to flower?—OLD SUBSCRIBER.

[You will find the following dozen varieties free-flowering: Winter Cheer, a brilliant

Cactus Dahlia Albion. From a flower exhibited by Messrs. Burrell & Co., Cambridge.

is good. This for garden decoration still has its uses.

LORD ROBERTS.—This variety is by far the most elegant and true Cactus-like sort we have. In growth it is excellent. The stem is good, although the blooms are somewhat pendent. The flowers are not pure white. There is room, therefore, for improvement.

EVA is a new variety with pure white blossoms, and if it is as good in the hands of others as exhibited by the raiser it will be welcome.

ALBION.—This (see illustration), raised by Messrs. Burrell and Co., Howe House Nurseries, Cambridge, is, I think, the choicest new white variety yet seen. The flower is pure white, the centre slightly creamy-white. It has very long, elegantly-formed florets, and being of good habit and carrying the flowers on stiff stems, will be very useful in the garden. It received a first-class certificate from the

varieties of the semi-double type can thus be raised from seed, such a class merits all possible encouragement. At Kingston we have classes for both double and for single Primulas, but the former are to be real doubles, and, of course, propagated plants. Of both classes at the recent show the plants taking first prizes were remarkably good. It has always been to me matter for wonder that the best doubles I see at any show invariably come from Leatherhead. It does not follow that the air of that district gives growers special advantages. What is probable is that all have well learned the secret of culture. Where plants measure from leaf to leaf some 18 inches, and the heads of bloom are as relatively broad and massive, without being in the least drawn, it is evident that the cultivation of double Primulas is well understood. Propagation usually takes place towards the end of February, after the plants have

scarlet with a shade of crimson; Reginald Godfrey, rich salmon-pink, a large flower of good shape, a strong grower, and sturdy habit; Flora Hill, one of the best whites and sweetly scented, as well as free-flowering; William Robinson, a rich scarlet of fine form; Mrs. Leopold de Rothschild, a beautiful salmon-pink flower; Exmouth Gem, a salmon-blush, blooms freely, and the plant has a good constitution; La Neige, a pure white, not so large as some but very free. Christmas Cheer is good, with rich salmon flowers freely produced; Mary Godfrey is a grand white, and the plant very sturdy; Deutsche Brant is a very pure white fragrant flower; Mrs. Thos. W. Lawson, of American origin, has a fine pink flower of good size, and the plant vigorous and free-flowering; Yule-tide is a rich glowing scarlet of fine form and substance, and the plant very free. The plants will be in full bloom in nine months after putting in the cuttings. If taken off with

heel attached from the lowering growths of plants early in January, morely removing a little of the under Grass and placing half-a-dozen cuttings around the side of a 3-inch pot filled with light sandy soil. Place under a bell or hand-light in a temperature of 70 degs., with a little bottom-heat, and shade from the sun. In three or four weeks they should be fit to place singly in the same sized pot, keeping in the same temperature and near the glass roof until April, when stand in a cold-frame. Repot when necessary, and pinch out the point of the shoot soon after potting off the first time, and again when established in the pots they are to flower in—namely, 5½ inches and 6½ inches in diameter. Cuttings can also be put in during October and treated similarly as above. These would make larger plants, having twelve months to build up the growths instead of nine as before mentioned.]

Hardy plants in pots.—Many hardy plants that are of particular service in the borders in spring and early summer may be used to advantage in the greenhouse by potting them in October, and after they have become established bringing them into gentle heat. For such a purpose one thinks of Spiræas, Campanulas, Dielytras, Forget-me-nots, Doronicums, and Irises. I think we are disposed to overlook altogether plants of a hardy nature when potting bulbs, etc., and that is the reason why in many houses in spring, apart from bulbs, there is a want of variety; but this may be remedied by planting into pots in autumn some of those mentioned.—W. F. D.

Growing Cyclamen.—I should be glad if you or one of your readers could give me some information with regard to growing Persian Cyclamen? My corms, which are two years old, were re-potted in the early autumn, when they began to make leaf, in a compost five parts peat, four parts loam, three parts leaf-mould, and some sand and old mortar-rubbish, and are standing in an airy greenhouse on ashes about 2 feet from the glass; temperature from 55 degs. to 60 degs., but sinking last week during the cold nights to 50 degs. The house is well ventilated every day when the weather is mild. The leaves, however, are coming small and weak, and flowers small, many of them dying off before even advanced enough to show colour. My plants have not been allowed to get dry, but have, if anything, been kept rather damp. Should they be given liquid-manure or weak, diluted guano as soon as they begin to root? I see plants in shops full of sturdy leaves and large flowers. I had the same experience with the same corms last year, having a fair number of flower buds, about half of which developed into small flowers, and the other half withered away. Any information will much oblige.—C. L.

[This plant requires very careful watering as soon as the flower buds appear; it should not be allowed to touch the buds from the end of September onwards, and the plants require all the light it is possible to give them. Shelves within 1 foot of the glass roof are the best position for this plant until the flowers are well up among the foliage, when they may be removed to the staging, and even there the plant should be raised on a flower-pot so that air can play around it. In potting Cyclamens, the corms ought to be kept well up, so that the crown of the corm stands clear of the soil, and, if this is the fault with yours, remove a little of the soil with a label, and keep the plants a trifle drier at the root. Plants with plenty of roots working down around the sides of the pot are benefited by an occasional dose of manure-water, not strong, say, twice a week; weak guano-water is suitable for a change. Examine the centre of the plants every few days this time of year, removing at once any decaying matter, or it soon contaminates flower buds, also the young leaves. Cyclamens do not require peat when you have good fibrous loam and good leaf-mould, the two latter in about equal parts, the loam predominating, if anything, adding a 6-inch pouf of bone-meal to every bushel of soil, using plenty of coarse silver-sand to keep the whole porous. The temperature appears about right, though during cold nights the plants would take no harm if the thermometer fell to 40 degs., but, as before said, the plant dislikes a stuffy atmosphere when once the flowers begin to push up, and the finest specimens are to be found growing where plenty of fresh air on every favourable occasion can play around them. Sometimes the tiny small yellow thrips will attack these plants and cause the flower buds to shrivel; fumigating once a fortnight with N.V. vaporising compound will generally clear them.]

GARDEN PESTS AND FRIENDS.

THE MARGUERITE DAISY-FLY (PHYTOMYZA AFFINIS).

I HAVE been very much troubled with the leaf-mining grub during this season; Chrysanthemums, Cinerarias, and Marguerites alike have suffered. I shall be very much obliged if you will give me a description of the fly which produces this grub? Does it lay its eggs during the winter months, or only in summer? Does the grub become a perfect fly during winter, under glass I mean? I am sure the history of this pest will be welcomed by your readers in this district at the present time.—J. T. B., Bolton.

[The leaves of various plants belonging to the natural order Compositæ, or Daisy-like plants, particularly those of Marguerite Daisies, Chrysanthemums, and Cinerarias, are often much injured by the grubs of this destructive fly, which burrow into the leaves and feed on their inner substance. When many leaves are attacked in this way the plants are not only rendered unsightly, but suffer in health very considerably by so many of their leaves having been rendered useless. The attacks of these grubs may at once be recognised by portions of the leaves losing their colour and appearing blistered. In the figure the darker parts of the leaves are those which the grubs have not yet reached, and the oval blisters show the

Fig. 1. Marguerite Daisy-fly (*Phytomyza affinis*): 2, grub of; 3, chrysalis of (all magnified); 4, leaf mined by grub.

positions of the grubs, and the small black dots their droppings. The most certain method of destroying this insect is to go carefully over the plants as soon as it is noticed that they are attacked, and pick off any leaves which are so badly infested as to be rendered useless; these should immediately be burned. In the other leaves the grubs may be killed by pinching them firmly at the place where the grubs are. By placing the plant towards the light so that you can look through the leaves, the position of the grubs will be easily seen. When the grubs are very young their position can only be detected by a small, greenish, transparent spot, about 1-10 inch in diameter, in which is the grub, and running a needle through the leaf at this point would probably kill the grub. When plants which have been infested are cut down after flowering, the parts cut off should be burnt, and not thrown on to the rubbish-heap, for if any of the grubs are full grown they will undergo their transformations just as if the plant were still growing. Various washes have been recommended, but it is very questionable if they are of any practical value, for if used of sufficient strength to kill the grubs, through the skin of the leaf, they would probably injure the sound leaves. The fly usually makes its appearance in the spring, and lays its eggs on the undersides of the leaves, probably just under the skin. The grubs attain their full

size in the course of a fortnight or three weeks. They then work their heads through the skin of the leaf, and become chrysalides, from which the flies emerge in due course. If the grub did not make provision in this way for the escape of the fly into the open air as soon as it leaves the chrysalis, it would not be able to make its way out of the leaf. There are several broods of this insect during the summer, so that it is very important to kill as many of the grubs of the first brood as possible. The Marguerite Daisy-fly is a small insect, about 1-10 inch in length, and measures not quite a ¼ inch across the wings. The general colour of the fly is blackish-brown, but the head between the eyes, which are red, is paler, and so are the edges of each joint of the body—the knees. The head and body are sparingly covered with stiff black hairs. The grubs are of a pale, transparent green colour, and when full grown are about 1-10 inch in length. They have no legs. The chrysalides are about the same length as the grubs, but are somewhat stouter. The joints are very well defined.]

Paraffin emulsion (F. W.).—There are various recipes for making paraffin emulsion which vary in their proportions, according to the purposes to which they are going to be put. Some plants will not bear such a strong dose of paraffin as others, some resent too much soap, so that no hard-and-fast rule can be laid down in the matter. The recipe in most general use is that known as "Cook's." Dissolve 1 quart of soft-soap in 2 quarts of boiling water, while hot add 1 pint of paraffin-oil, and mix the two together till an emulsion is formed by stirring or working it through a syringe for five or ten minutes, when an emulsion should be perfect. Dilute this with ten times its volume of water, more or less according to circumstances.—G. S. S.

Common gnat (Blozham).—The insects you forwarded are specimens of the females of one of our common gnats. The bite of these insects, as you say, is very irritating. It is a curious fact that it is only the female gnats that bite and suck blood. The mouths of the males are so formed that they cannot pierce the human skin. Several kinds of male moths have practically no mouths at all. It is also singular that, considering the enormous numbers of female gnats and midges that exist without ever getting the chance of tasting blood, the comparatively few that do gorge themselves with a food that is unknown to them, and which their ancestors for, perhaps, many generations have not tasted. How can they know that blood is fit for food?—G. S. S.

VEGETABLES.

SEED POTATOES.

I DIFFER, with all deference, from your correspondent, "T.," p. 515, when he says that seed Potatoes may be kept very well in the dark. That might be true enough were the temperature of the store low, so as to preclude premature sprouting, but it is more difficult on the whole to keep the temperature of a dark, and, therefore, close, place low, than one that is fully exposed to the light and, naturally, to the air. Just now natural temperature is high, and it is not possible to keep a Potato store low with an external temperature high. For that reason it is of the first importance seed tubers should be in the light, because should, under such conditions, premature growth follow, and it is almost certain to do so, then the shoots are stout and green, and do not elongate or become waste. I have my own seed tubers in a very light store, where ample air is always admitted unless the weather bids fair to be severe. If so, then the temperature falls, growth is arrested, and the tubers remain at rest. Our winters are so varied and changeable that we seldom get a week's continuance of the same weather, and when higher temperature follows the cold, there is on the part of the seed tubers a quick rebound, and growth begins again, even more rapidly than before. To check these oscillations of temperature I leave the windows closed for a few days, boxing in the cold until the indoor and outdoor temperatures gradually

accord. It is of the first importance that an equable temperature be maintained so far as possible, but that cannot always be so, hence it is important that when shoots grow they should be in full light and have plenty of air. Already early ripening tubers are pushing, and if we have a mild winter, as seems very probable, late varieties will soon be starting growth also. Few things in Potato culture are of greater importance than is the keeping of the seed tubers under the best possible conditions during the winter. A. D.

PROTECTING CELERY.

(REPLY TO "MIDDLETON.")

The decay of Celery is more often than not due to other causes than frost. During severe or prolonged frost a little protection of great assistance, but the continual covering and uncovering of the rows which some people subject their Celery to must be injurious. It is very annoying after trouble has been taken to have good Celery to find that at

and snow were to follow directly afterwards, it would lie very close, and afterwards when a thaw set in, it would become a wet and sodden mass, and the Celery would suffer accordingly. Damp is the worst enemy to Celery. Celery will suffer more than usual from damp this season on account of the very open weather which we have experienced.

Whatever form of protection is used it must be so arranged that both light and air can have free access. Covering over with a cap by having two boards nailed together thus **A** has been frequently recommended. Celery that has been forced into a coarse growth by heavy applications of liquid manure and the too free use of artificial fertilisers is always the first to succumb.

TREES AND SHRUBS.

VIBURNUM TOMENTOSUM.

This is closely allied to the Japanese *V. plicatum*, from which it differs chiefly in its more

London atmosphere will prove too much for many of them. Again, the height of the fence will prevent the employment of vigorous climbers, as they would need so much cutting to keep them within bounds that few, if any, flowers would result therefrom.

You have the choice among other subjects of the many beautiful varieties of Clematis, among which the range in colour is now great; while *Jasminum nudiflorum* is valuable from the fact that its golden blossoms are borne in mid-winter, and its near relative the common white *Jasminum* is a summer flower, and a universal favourite. The cut-leaved Grape-Vine and the purple-leaved form are both very pretty. Others that can be recommended are *Cotoneaster horizontalis* and *C. microphylla*, neat berry-bearing shrubs; *Crataegus Pyracantha* (Fire Thorn), whose scarlet berries form such a showy winter feature; *Cydonia* or *Pyrus japonica*, of which the varieties vary in colour from white to crimson, and bloom in the winter and spring months; *Forsythia suspensa*, with bright

Viburnum tomentosum at Coombe Wood. From a photograph by G. A. Champion.

In winter the greater part has decayed. There is no doubt that the form of earthing which is adopted has much to do with early decay. By earthing too early, the blanching is done much too soon; consequently after a decay commences, let protection from it be ever so efficient. In Celery that is protected fermentation sets in through lack of air and close confinement. Celery, to keep well, must be well moulded up. The beds should be well sloped up and made fairly smooth, the soil being also well worked in around the top of each plant, all of which should, when earthing is finished, be exposed about 6 inches. Heavy coverings of litter or bracken laid along the tops of the rows cannot but have an injurious effect, and late Celery will be in a worse condition at the turn of the year than even if left freely exposed.

The best plan, if the weather should become unusually severe and there is no covering of snow, is to lay some dry litter or bracken fern along the sides of the rows and then to shake a little of the very lightest and driest loosely along the top. If a heavy covering is put on

with hairy leaves and in its sterile flowers being confined, as in *V. Opulus*, to the outer part of the inflorescence. The habit, as may be seen by our illustration, is spreading, the branches having a somewhat table-like aspect. The flowers are borne freely, those at the circumference of the umbel being five or six in number, and forming a very elegant collar encircling the central flowers, which are very small. It is by some said to be not so hardy as *V. plicatum*.

CREEPERS FOR FENCE.

I SHOULD be so much obliged if you would give in your most useful paper a list of suitable creepers for growing upon a 6-foot matchboard fencing which goes round three sides of a garden, the soil being a very dry one? I shall be grateful for suggestions.—C. M. S.

[There are a great many beautiful plants of a shrubby character suitable for growing up your fencing, but, of course, they would need to be secured thereto. One's thoughts naturally turn among other subjects to Roses, but if the garden is situated at the address from whence you lettered to us, written we are afraid that the

yellow blossoms in early spring; *Viburnum plicatum* (Japanese Snowball Tree), flowers in May; *Kuonimus japonicus aureo variegatus*, *argenteo variegatus*, and *radicans variegatus*, all three pretty variegated leaved kinds of *Euonymus*. The only plant that will attach itself without any support is *Vitis inconstans*, far better known as *Ampelopsis Veitchi*, which is so freely planted in suburban districts. The numerous *Ivies*, too, are available for the purpose you mention, and for the shaded portion of your fence they are particularly valuable.

Of climbing subjects other than those of a shrubby character mention might be made of the Everlasting Pea, which is always admired; *Apocynum tuberosum*, with curious purple flowers; and *Calystegia pubescens flore pleno*, a pretty double pink Bindweed. You could also, if you like, put out during the summer some of the better *Tropaeolums*, *Convolvulus*, *Mina lobata*, and that pretty climbing Dahlia, *Hidalgoa Wrecklei*. We note your remark upon the soil being very dry, and to counteract this as far as possible the ground should be deeply

dug before the climbers are planted, and some cow-manure incorporated therewith, as this is by far the best stimulant for dry soils. Again, in planting, a saucer shaped depression may be left around the stem of each, as this greatly facilitates artificial watering, which may be necessary till the plants become established.]

FRUIT.

MILDEW ON VINES.

Thisinery of this rectory, to which I came in August, contains several Vines, all of a healthy nature. Mildew had set in when I came, and all the fruit had to be destroyed. I attribute the mildew, whether rightly or not I do not know, to want of attention to the border—to the fact that the fruit was not thinned out at the proper time, and that my gardener, who never had much success with the Vines, kept a barrel of water in theinery and another tank outside which constantly overflowed, as it caught the rain-water from theinery roof, and saturated the soil. I burned sulphur, and kept some in open pans in the house, but the only apparent result was that the leaves and fruit of a good Fig-tree on theinery were destroyed. I wish to know what I should do to (1) the border; (2) the Vine itself; (3) the walls and glass; (4) the floor, and when your recommendation should be carried out? The branches of the Fig-tree and those of a Nectarine appear to be infected now, as are also the leaves of some Chrysanthemums in pots.—*FRIDA.*

[Your Vines are evidently in a bad way, and we would strongly advise you to lift the roots of the Vines, carefully working away the soil with a five-tined fork, preserving all the roots as the work proceeds, and tying them up in pieces of hag or matting after damping the roots. Then after getting out all the soil, examine the drainage and see whether the water can freely pass through the same, and if it is found to be at fault, remove it and pass it through an inch sieve to get out all the small, when you may return the same, which should be 8 inches or 9 inches in depth, after making quite sure the water, after passing through the border, has an outlet. If not naturally, place 3-inch drain-pipes 4 feet to 6 feet apart at the bottom of the drainage. These must lead to a main drain outside your border, having a gentle fall to the lowest point. Next, get some Grassy turves 2 inches thick, and place over the drainage, Grass side downwards. These will prevent the finest portions of the soil from getting amongst the drainage. Your new border should be from 1 foot 9 inches to 2 feet deep, and if you could procure enough maiden loam from a pasture to make it entirely new, so much the better, or if this is inconvenient and you could get one-half new loam and mix with the old soil, such a compost would last several years, working in a fair percentage of old plaster, lime-rubble, or charcoal, well mixing all together and filling in when not too wet, well firming the soil until within 6 inches or 8 inches of the border's level. Next, place the Vines in position, laying out the roots evenly over the newly-prepared border, first cutting away any bruised or mutilated pieces, then fill in with the soil, make firm, and tie the Vines loosely to the trellis, and do not apply water to the border until the Vines are breaking nicely. Such work would have been better carried out at the end of October, when with foliage attached the roots of the Vines would soon have laid hold of the new soil. As it is, you had better defer the work until March. In the meantime get your Vines pruned, scrubbing with soapy water at a temperature of 100 degs., then make a thickish paste of flowers of sulphur and paint every particle of the Vine, well working it in between the spurs. The woodwork, also glass, should be thoroughly washed down before tackling the Vines, or before the new border is put in. It is more than likely that the constantly overflowing tank on to the border during early spring and summer caused, or greatly augmented, the rapid spread of mildew. Keep a constant watch over the Vines as soon as in leaf, and should it again appear, dust with flowers of sulphur immediately. You do not say whether your house is heated or not. Of course, mildew is more likely to attack the Vine in unheated houses, and greater care is necessary as regards moisture about such structures.

You made a great mistake in burning sulphur in the house. Sulphur must not be ignited in any way, as that would to a certainty not only destroy the mildew, but the Vines also. We have seen Vines so treated and destroyed. The burning of the sulphur

was the cause of your Fig-trees losing their leaves and fruit. In fact, it is to be feared that all the plants you have in the house have been killed.]

FRUIT GATHERING AND PACKING FOR SALE BY SMALL GROWERS AND COTTAGERS.

For the purpose of eliciting some practical information with respect to fruit gathering and packing for sale, the Fruiterers' Company, of London, recently offered the valuable prize of 25 guineas, and a gold medal for the best essay on it, not exceeding 25,000 words in length. The judges of the eight essays sent in were Messrs. Asstee, manager of Covent Garden Market, Mr. G. Gordon, of the *Gardener's Magazine*, and Mr. A. Dean, of the R.H.S. fruit committee. The object aimed at was the production of an essay such as was lucid, practical, and well written, and that would be creditable to the company to publish at a low cost. The fortunate winner was Mr. R. Lewis Castle, manager of the Duke of Bedford's Experimental Fruit Farm at Ridgmont, Bedfordshire, and who has had considerable experience in packing fruit in small utensils for sending to all parts of the kingdom. There can be no doubt that fruit culture by small growers is in this country materially hampered because of the difficulty of finding suitable markets for small quantities. This the small grower rarely can do in large markets, not only because of the cost, but also because of the distance. What is needed is that small growers should co-operate, have their fruit in the season collected, marked, then in bulk taken or sent to the nearest markets. For that purpose it is most important that they should gather their fruit with the greatest care, assort or grade it into best and seconds, so that the top layer in all cases fully represents the bulk, and also that the fruit be put into neat, cheap, and non-returnable packages of wicker or wood, and be in small quantities, such as will suit private purchasers, who could in that way obtain their fruit direct from the grower without the aid of any dealer or middleman. In the prize essay named all the matters essential to success in the directions desired are referred to clearly, and are assisted by simple drawings. Even the making of bags, boxes, and baskets at home is described, the work being such as small growers and cottagers can well undertake in the winter months. In some places small growers can find markets close at hand. In other cases they can work up a trade by advertising, then in well-packed utensils sending by carrier or by rail. Of course, good fruit can only be obtained by good culture and growing the best varieties. A. D.

NOTES AND REPLIES.

Nailing trees to walls.—I have fruit-trees growing on a stone wall and find a difficulty in tying them to it. The mortar will not hold nails, and I cannot get nails to drive into the stone—they all turn up. I suppose I must use wire; but I do not like it, as it cuts the trees. Please advise me. Is there any nail that will drive into and hold in stone?—*H. SHAWCROSS.*

[If your wall is built of soft stone then the cast wall nails should answer, but we should advise you to have the wall properly pointed and wired, giving the wires two coats of white-lead paint. By this system nails and shreds are dispensed with, the walls are not injured in any way, and insects are not harboured. The tying of the trees, too, can be done more quickly than by the old system of nailing.]

Pruning newly-planted trees.—When, and how much, should I prune fan-trained Peach, Apricot, Plum, and (dwarf) Cherries which were planted in the middle of this month against a wall? In pruning Peach-trees, should they always be cut to a triple bud?—*R. W.*

[There is always a certain amount of doubt in the minds of amateur growers as to the amount of pruning that should be done in the case of newly-planted trees. The question depends entirely on the state of the trees themselves to be operated on. Some received from the nursery are from their treatment there in such a state that no pruning is called for at all, and a tree that a nurseryman has been devoting time and labour to to mould it into a good shape certainly ought not to need much aid from the new owner. In the case of a trained tree, however, a better course can be taken than to follow the

rules set up in the nursery. The extremities of leading shoots may be shortened if the branches are not uniformly disposed, and in cutting a Peach shoot it is always desirable to cut to a wood or a triple bud, or not to cut it at all. Weak shoots are always best cut back somewhat hard, for if allowed to grow unpruned they do not break evenly, and the basal buds, which are the most important ones, will fail to break at all. The object in training trees should be to make sure of getting them well furnished at the base. The pruning may be done at any time from now till next February. Before nailing the trees make sure the soil is settled and firm, for it sometimes happens that after a tree is fixed to the wall the soil, if at all hollow, will settle down and leave the root unsupported, with the inevitable result—collapse.]

St. Joseph Strawberry.—In a 10-20 number damp is given as the cause of mildew attacking this. I do not think this is the cause. In this district hardly a fruit has come to perfection, even in the very dry years we have recently had—in fact, growers have noted them up wholesale. The district I write from is a limestone one; I have heard of this variety doing well on dry, sandy soils. I have tried it under glass, and cannot get a fruit without it is mildewed.—*NORTH CORNWALL.*

Alpine Strawberries in greenhouse.—I have a few dozen plants of alpine Strawberries—St. Andrew, Ladoue, and St. Joseph—which were potted up last August and are now well established. Would these varieties succeed if forced on gently in an ordinary greenhouse, placing them inside, say, in February or March, so that all blooms showing before that time be picked off?—*E. W.*

[These introduced in February or March should succeed very well under ordinary greenhouse treatment. Much, however, depends on the greenhouse itself as to what success is likely to be obtained. With a nice light and warm greenhouse, having shelves to stand them on, these perpetual Strawberries by some can be grown during the winter months, but though some succeed, others would fail. There is every willingness on the part of the Strawberry to fruit—that is to say, flower spikes are formed freely, and fruits swell up a certain size—but when they approach their ripening period they slow down and do not always realise the anticipations of the grower. When in March the days lengthen, and the sun has more power, there are more life and progress in Strawberries of every sort. It would be as well to remove the present formed trusses of flower from those you propose to fruit in March, and some of those fruiting freely now could, if you so wish, be kept steadily moving in the greenhouse. You may then get a few ripe fruits early in the New Year. Those to remain for later use should have some protection from frost—the pots, if nothing else can be done, should be plunged in ashes, leaves, or Cocoa-fibre, or the pots may suffer as well as the roots should frost set in with any degree of severity.]

GARDEN WORK.

Conservatory.—Pelargoniums, especially those for early blooming, should be in their flowering pots. When potted late they do not flower so well, and the growth is less robust and dwarf. Firm potting is essential to freedom of flowering. Where the plants are well done they do not appear in the conservatory till the flowers are on the point of expanding. A light, airy house is the place for Pelargoniums, with a night temperature of 45 degs. to 50 degs. now, and till the days lengthen water is being given only when dry, and then all the soil must be moistened. A keen watch should be kept upon insect life, and the vapourer used when the first fly is seen. Under such conditions the Pelargonium is a tower of strength in the conservatory, and will give a brilliancy equal to the Chrysanthemum at less cost. Give Geraniums, Arum Lilies, Cinerarias, and other plants coming into flower weak liquid manure. I am going to recommend any special kind of manure—chemical or otherwise—to make liquid manure. Those who have a farmyard, or a deer park, or sheep pasture to run to may generally obtain what stimulates them, requires without incurring much expense. These chemical or proprietary manures are all rather dear, but I am not sure if there was a general run-

for them they might doubtless become cheaper. All are good for certain plants and purposes, and when it is necessary to make a supreme effort to win a prize sulphate of ammonia will be useful in giving the finishing touches to the blossoms. Cleanliness is as important in plant houses as in the structure where human beings live. Dead leaves should be removed at sight, green, slimy pots should be washed, and borders should often be freshened up with the rake. These and other little matters, which the good cultivator understands the value of, must have attention from time to time. In sweeping paths in the conservatory avoid raising dust, which often clings to the leaves and stops up the pores and gives the plants a forlorn appearance.

Ferns under glass.—A good collection of Ferns has a special interest in winter when in good condition, and the way to have and keep Ferns in good condition is to have a young plant or two of each kind continually coming in, and to discard the plants of the same variety or species when they get old and out of condition. Of course, now that Ferns are so much used for indoor decoration, there will probably be many duplicates of certain kinds available for that work. These for the most part will be found among the greenhouse species. Where there is much indoor decorating to do there is not likely to be too many Maidenhairs, especially of the old familiar types—cuneatum and elongatum. Maidenhairs of small sizes are useful for table decoration, and, if they suffer injury, they soon recover when taken back to a warm-house. Among the Pterises, cratica major and cretica cristata are most useful, because they can be kept in condition longer than most. Pteris tremula and argyrea are exceedingly useful for a change; the last-named has broad, variegated fronds, very striking, but will not last so long in a room as the hardier forms of Pterises first named. Phlebodium aurum has a striking appearance, but will not last so long in a low temperature as others named. One of the most useful and hardiest of Ferns is known among connoisseurs as the Holly Fern (*Cyrtium falcatum*). I have seen this Fern in sheltered places doing well outside. It is one of the few Ferns that keep in condition where it is burnt, because of the hardness of its foliage. If the thrips get established on its hard, glossy points, the green matter is soon eaten away. This is the one enemy to this very useful Fern. More loam is used for this class of Fern than was usual years ago, and the plants in consequence produce more robust and amply foliage, which renders them useful to the average grower.

Early Peach-house.—This house will now be ready for starting, and if the trees have been forced in previous years the buds will start at the right time without much forcing. Cleanliness everywhere is most important. Trees, paint, glass, and walls should have undergone the usually preparatory routine of cleaning. The border, also, should have been renovated, so far as the surface is concerned at any rate. It is always a good plan in the case of all fruit-houses to remove, at least once a year, the exhausted soil from the surface of inside borders, and replace it with good loam, enriched with bone-meal or some other suitable manure. The red-spider is often a troublesome enemy in the early Peach-house, and some rains should be taken to clear it out now, to save labour and trouble in summer. One cause of the presence of red-spider is dryness at the root, and every dry spot in the Peach borders should be hunted for and moistened now, even if in using the fork some little disturbance of the roots should take place. Any little damage is soon made good if the soil is thereby made more suitable for the roots to work in. A temperature of 45 degs. at night will be high enough to start with from fire-heat. During the late mild weather our houses have often stood between 45 degs. and 50 degs. without fire-heat; but this does no harm. Use the syringe as often as is necessary to keep the atmosphere sufficiently humid to give strength to the swelling buds, and ventilate at 60 degs.

Late Grapes.—Perfect ripening is necessary to long keeping. This has not been a good season for ripening late Grapes, especially where Gros Colman and Lady Elizabeth were

started late. It is better to use fire in the spring than put it off till the days are shortening in October. All that can be done now is to keep the atmosphere of the house dry; fire-heat will not avail much now beyond what is necessary to dry up damp.

Window gardening.—A stand in a light position arranged with Chinese Primulas, Cyclamen, and Roman Hyacinths, with a fringe of Ferns, is always pretty and interesting, and the fragrance is grateful without being too powerful.

Outdoor garden.—Roses may still be planted. The introduction of Rambler Roses has led to the planting of Rose screens or hedges in many gardens, and beautiful they are. They may be used to form backgrounds anywhere. All one has to do, after having selected the site, is to trench and prepare a space a yard or so wide and plantsuitable Roses. For tall screens, 10 feet or more high, the tall Rambler Roses should be used, the base being filled in with Chinas or Polyantha Roses. Hybrid Sweet Briars are also being planted to form hedges. I saw a hedge of this character the other day, very thickly covered with scarlet H.P.'s, very bright and attractive. In the summer this hedge was even more attractive, with its various coloured blossoms, several varieties having been planted. Those who have dwarf walls to cover will find the various forms of Eonymus very dressy and effective. The Laurustinus makes a very effective shrub for a wall up to 8 feet or 9 feet. It is best to start with quite a young plant. Berberis stonophylla is a specially valuable wall shrub, and there are now several varieties of Yrus japonica well adapted for covering low walls. For covering low terrace walls and the side walls of the steps, the various forms of Cotoneaster are very suitable, because they want no training, and consequently always look natural. Cotrus atlantica and its variety glauca are among the most beautiful of lawn trees, and are hardy.

Fruit garden.—Peaches may be pruned on open walls now when the weather is not frosty. These are generally left to the last, because it is necessary to cut to a wood-bud, and this is seen better when the buds are getting a little prominent, otherwise there is no reason for delay, though when there is much pressure of work something has to be postponed. I never knew a gardener that was good for anything that ever had much leisure at any season. During the autumn the pruning of the roots of the over-luxuriant trees needs attention, but for trees of a moderate size I prefer lifting and replanting, bringing the roots a little nearer the surface. When we dig round a tree and cut the roots which are running down, we check them for the time being, but it does not alter their downward course in the same way that lifting does. Then when the roots have been attended to the branches receive their annual thinning and shortening. There is no difference of opinion about the treatment of wall-trees and espaliers, but there is still too much knife-work done to pyramids and bush trees. This is more seen now in suburban gardens than where a good man is placed in charge. Even in the case of wall trees it is an advantage to rearrange trees when crowded on a wall, and give each tree more space to cover rather than cut back.

Vegetable garden.—When taking up Seakale for forcing, the thongs or small roots removed from the strong stems should be cut into lengths of 4 inches or 5 inches, and laid in sand outside, and a little litter laid lightly over them. During the winter crowns will form at the upper end of the roots, and if planted in February or March in rows about 15 inches apart, strong crowns suitable for forcing will be available next year. All available frames will now be in use for sheltering such things as Cauliflowers, Chervil, Parsley, or for forcing Asparagus, or anything else for which a demand may be expected. In country places, where there are many trees, the leaves form a valuable crop worth gathering and taking care of for forcing, and afterwards are valuable as a manure. It will require a warm-house to produce French Beans now, and the pots or boxes should occupy a position near the glass, and the individual plants not crowded. The principal demand now for the

choicer kinds of vegetables will be for Mushrooms, Seakale, and Asparagus. These may be produced at a reasonable cost, but French Beans are costly to produce in the dead of winter. In consequence of the scarcity of good Apples, Rhubarb should pay to force early, and those who have plenty of strong roots might start at once. E. HOBDAY.

THE COMING WEEK'S WORK.

Extracts from a Garden Diary.

December 8th.—Vaporised Cinerarias and Pelargoniums. Finished potting Hyacinths and plunged in fibre in cold-frame, with lights off for the present. A few Strawberries have been started in a leaf-bed in a pit, where there is a gentle fermentation going on. The watering will be carefully done, as an excess of moisture will cause too much leaf development. Mico have been helping themselves to the red berries of Solanums, and traps having failed, and the matter being urgent, we have been obliged to use poison. This has checked their work.

December 9th.—As soon as pruned, Gooseberries and Currant-bushes were dressed with lime and soot, scattered over the trees when the branches were damp. The dressing has some value as a cleansing and manuring agent besides its deterrent effect upon the birds. Roses in pots and also those planted out under glass have been pruned and top-dressed. A few have been potted up from outside for late blooming and to come in for early flowering next year.

December 10th.—Endives are taken to the Mushroom-house a few at a time to blanch. Rhubarb and Seakale roots are introduced at necessary intervals to ensure a succession. When a Mushroom-bed ceases to bear, the material is removed and the space filled up again from open shed near where it has been fermented in readiness. We are still using retarded Lily of the Valley crowns for forcing, although our autumn stock has come to hand.

December 11th.—I thought, a few days ago, we had finished planting Roses, but fresh sites have been found for pillar Roses and Ramblers, and these are so beautiful and free, one is tempted to plant them wherever a support can be found. We have generally a piece of ground waiting for trenching. There are days when the ground is too wet for surface work, but trenching can be carried out, even in wet weather. Rearranged stove to give growing plants more room.

December 12th.—Carted in a lot of turfy loam from the surface of a pasture, and placed in ridge-shaped heaps. One heap has been mixed with alternate layers of horse-droppings for Polargoniums, Fuchsias, Chrysanthemums, and other things. This, when chopped down in six months' time, will be ready for use. Pot-Vino house is kept at a temperature of 30 degs. at night. Buds are swelling. A little air is given at 65 degs. when the sun shines. Figs in pots have been pruned and top-dressed.

December 13th.—In bad weather the sponge is used among Palma and fine-foliaged plants. Liquid-manure is given to Camellias swelling buds. Fern spores which have come up thickly have been transplanted in patches or colonies into shallow boxes and kept on shelves in warm house for the present. When the days lengthen the patches will be broken up and extended. Mustard and Cress are sown in shallow boxes twice a week in warm house. Seeds are not covered.

LAW AND CUSTOM.

THE GARDENER AND THE CITIZEN.
COURT OF KING'S BENCH. MAXFIELD C. ROSS.
MR. GARROW observed that this was an action brought by the plaintiff, a gardener, to recover of the defendant the sum of £11, the balance of £26 for fitting up his garden at the back of his house. The defendant had paid £16 into Court, and contended he had been overcharged the other £5. The plaintiff, said the learned counsel, was one of the most eminent in his ancient and honourable profession; he had been for years employed in keeping in order

the delightful garden, which constituted the ornament of Queen's-square, and it was no small proof of his superior ability that he had the cultivation and improvement of those sweet and pleasant gardens, more fresh than the Bower of Irem, the air of which gave mildness to the spring, and the scent of whose herbs refreshed the spirits, and conveyed perfume to the very soul; in short, he had been selected, by the noble lord who presided in the Court opposite (the Court of Chancery) to decorate the enamelled spot in which his lordship unbent his mind, after the painful labours of his professional duty; to speak in plainer language, he was gardener to Lord Eldon, and, consequently, must be supposed to be a man of character, and one who would not make an unjust charge. The defendant was a gentleman of fortune, residing in Red Lion-square; and, being desirous of uniting in his town house the pleasures of a country one, applied to the plaintiff to afford him, by the exercise of his art, all the advantages of a *rus in urbe*. He was one of those London-country gentlemen who wished to have—

"Within their walls their shady groves and
Their flow'ry gardens and their green alleys;
In midst of winter to enjoy the spring,
And hear the captive birds in cages sing,
The city air perfumed with sylvan sweets,
And rural walks combin'd with crowded streets."

Such was the ambition of the defendant, and the plaintiff had completely gratified it. He had converted the limited space behind the defendant's house into the most delightful garden imaginable—Rose-bushes, Jessamine, and sweet flowering shrubs were planted along agreeable walks and alleys green; and whatever could charm the senses of the defendant, or make him imagine himself another Rinaldo, in the Bowers of Armida, was profusely provided. Having completed his task, he naturally expected to be paid, but the defendant, though he had expressed himself perfectly satisfied while the work was going forward, refused to remunerate him, alleging that his charge was exorbitant. Lord Ellenborough made a few observations to the jury, who immediately found a verdict for the plaintiff.—*Times, 1802.*

CORRESPONDENCE.

Questions.—Queries and answers are inserted in *GARDENING* free of charge if correspondents follow these rules: All communications should be clearly and concisely written on one side of the paper only, and addressed to the EDITOR OF *GARDENING*, 47, FURNIVAL-STREET, LONDON, E.C. Letters on business should be sent to the PUBLISHERS. The name and address of the sender are required in addition to any designation he may desire to be used in the paper. When more than one query is sent, each should be on a separate piece of paper, and not more than three queries should be sent at a time. Correspondents should bear in mind that, as *GARDENING* has to be sent to press some time in advance of date, queries cannot always be replied to in the issue immediately following the receipt of their communication. We do not reply to queries by post.

Naming fruit.—Readers who desire our help in naming fruit should bear in mind that several specimens in different stages of colour and size of the same kind greatly assist in its determination. We have received from several correspondents single specimens of fruits for naming, these in many cases being unripe and otherwise poor. The difference between varieties of fruits are, in many cases, so trifling that it is necessary that three specimens of each kind should be sent. We can undertake to name only four varieties at a time, and these only when the above directions are observed.

PLANTS AND FLOWERS.

Michaelmas Daisies (E. S. W.).—Good varieties are: *Aster Amellius*, A. *lesparabicus*, A. *acris*, A. *cordifolius elegans*, A. *Coombe-Pishare*, A. *lavis*, A. *Novae-Angliae*, W. *Bowman*, A. *Novi-Belgii*, Robert *Parker*, A. *Shottii*, A. *Chapmani*, A. *diffusus horizontalis*, and A. *eritoides*.

Achimenes (W. W.).—Start your tubers of *Achimenes* and *Tydaea* next February in boxes filled with leaf-mould, Coco-nut fibre, or some other light material, potting afterwards into turfy soil, well-rotted leaf-mould, and sand. If you wish to grow the *Achimenes* in baskets, place the tubers all round so that at the blooming season little of the framework may be seen for flowers.

Roses for seaside (L. Sweeten).—Where the soil is good there should be no difficulty in cultivating Roses in close proximity to the sea. There may be a small amount of truth in the statement that the salt spray in the air has a somewhat deleterious effect on the plants, but we have generally found that where flowers by the sea have failed, the shallow and chalky soil has been responsible. Recently we found Roses flourishing beautifully around Eastbourne, some masses of such lovely kinds as William Allen Richardson, Laurette Messimy, Perle d'Or, etc., being most profusely in bloom and in rude health. Doubtless Tea, Hybrid Tea, China, and Polyanthus are the best to grow in seaside districts, and as the collection is now so numerous, a beautiful Rose garden can be formed of these plants.

Ixias in pots (Mab).—Seeing that your Ixias are showing growth, you should remove them from the plunging material and place them on a shelf in a cool greenhouse near the glass. Water moderately, and, as the shoots advance, give liquid-manure at alternate waterings. Water less after the flowers fade, and, as the leaves show signs of yellowing, withhold water altogether, and keep the bulbs quite dry until the potting season comes round again.

Lilium longiflorum (P. L. L.).—This is one of the most manageable and least capricious of the Lilliums. Its large, white, trumpet-shaped blooms are very handsome, and as the plant itself is a moderate grower, the flower-stalks do not run up so high as is the case with many kinds; the flowers, therefore, are not so likely to become bruised in stormy weather. This Lily likes a good, sound loam to grow in, and prefers a partially-shaded, somewhat cool situation. There are many varieties of it.

Sweet Peas in winter (Frankley).—There is always the risk of severe weather and mice and other pests destroying Sweet Peas which have been sown now. You can assist them by protecting with coal-sashes along each side, and putting some small bushy stakes to them. A far better way is to raise in pots under glass in spring, and plant out, so long as the weather is the usual way, and thus keeping up a succession of bloom.

Treatment of Oleander (L. Bentley).—The Oleander is naturally a tall, loose-growing bush, and, if kept dwarf it is at the expense of bloom, for it is on the upper part of the long, flexible, Willow-like shoots that the flowers are borne. In all probability, the failure of the flowers to open is due to the non-ripening of the wood. Leave the flowers as they are, and give it as sunny a position as you can. In the summer stand it outdoors in a sunny place and water freely.

Flowering Stephanotis floribunda in small pots (J. M.).—This may be done by obtaining strong young plants and growing them on in a moderate temperature, where they can obtain plenty of sunlight and air. In summer they may be placed out-of-doors in a sunny spot, where the wood will get well ripened. This side shoots should then be spurred in to within 1 inch of the main stem, and early in September the plants should be removed indoors, and their shoots tied up to a trellis near the glass. If a little heat be applied in summer, the shoots will be emitted at every joint, all of which will flower profusely.

Cobaea scandens (Luty).—This is a capital climbing plant for a cool greenhouse. It also thrives against an outside wall in favourable localities in southern and western counties, and it will cover a considerable space of trellis-work during summer. It should be planted in light, rich soil, and, if watered liberally during the growing season, it will soon cover a large space and flower freely. If afforded some protection it will survive an ordinary winter. Plants of it may be easily raised from seed, which should be sown during spring in a frame or handlight. Cuttings also strike readily in a brisk heat in spring. This variegated form must be raised from cuttings.

Own root Roses (Duplex).—Roses "on their own roots" have many advantages over those that are budded, the most important being their ability to reproduce themselves from the base, even though a sharp winter cut down the growths to the ground. We do not recommend own-root Roses for very heavy soil. By throwing up a succession of shoots, a more continuous blooming is assured, and, when once established, the plants grow and flower freely. Tea Roses are especially good on own roots, but as these in our climate must of necessity be produced under glass, they should either be planted in summer or late in spring.

Forcing Gladiolus Colvillei The Bride (Tom).—This plant requires a varying degree of moisture, according to growth and the season—little at first, to be increased with growth, and the soil maintained fairly moist up to the appearance of first blooms. Towards the end of April ample supplies are essential. If the soil is good there is no need for artificial manure, but if used it is best in solution—guano, for example. The plants should flower during April with fair treatment, in which we include the avoidance of too high a temperature. You will find a great lapse of time between the production of the last leaf and any sign of the coming flower-spike, and it is at this period that many mistakes are made in the culture of this useful plant.

Chrysanthemums—a good bronze Japanese sort, dwarf-growing and spiky (A. Cooper).—We are somewhat at a loss to know what you mean by "spiky." In the first place, however, we assume your plant must be a double one, and, in consequence, a freely-flowered specimen; and, in the second place, we also assume the florets of the blossoms must be stiff and straight, as nearly alike to a *Cactus Dahlia* in form as possible. If this is what you desire, we can recommend *Vivid*. This is not a bloom with pointed florets, yet it has stiff and straight florets of the kind likely to suit you. This colour is chestnut-bronze. A variety with twisted florets is *Sourire d'Or*, and, when grown freely, should develop blooms of a "spiky" kind. The colour in this case is an old gold.

Chrysanthemums—when to propagate early sorts (Voicer).—There is a tendency on the part of some growers to commence the propagation of early *Chrysanthemums* now, but such early work is a mistake. As a rule, the old plants are worth propagating at the close of their flowering season, and, in consequence, it would be better to shake the old stools out of their pots and plant them out in frames or on the bench of a cool greenhouse, leaving them thus until January. By the last-mentioned period new growth of a most desirable kind will be found breaking away around the base of the old stem. It is from cuttings of this kind that real progress is made. During January, February, and March, cuttings, if inserted with care, will root quickly enough, and, if potted on as soon as ready, will develop into sturdy little plants in a short time. It is surprising what a number of plants can be raised from a few old stools treated as here prescribed. Shallow boxes are useful in propagation, as, too, are 5-inch and 5-inch pots. The cuttings, if dibbled in 1 1/2 inches apart with rather more space between the rows in the boxes, succeed very well and rarely fail.

Chrysanthemums Soleil d'Octobre and Ralph Hatton (A. Cooper).—Both of these varieties mentioned above are worth cultivating. Soleil d'Octobre

as its name implies, is an October-flowering Japanese kind, of a lovely shade of canary-yellow colour. This plant is of very easy culture, and may be grown to develop large blooms, either in the orthodox manner, or on simple stems in 6-inch pots. As a plant for decoration this variety is also largely grown. Ralph Hatton is one of the newer incurved sorts, and is a bloom of large size and of excellent form. The colour is a purple-lilac, with more or less reverse to the very smooth florets. To see this variety at its best, and in the early days of November, the plants should be pinched or stopped towards the latter part of March, and second crown-buds retained.

Roses with divided centres (M. Cockle).—One of the strong doses of liquid-manure would certainly be one cause of the defective blossoms, and the want of artificial heat to enable the very double kinds to expand would be another. In unheated greenhouses it is always best to avoid very double varieties such as M. Cochet, Catherine Mermet, Ecole de Lyon, etc., but kinds such as *Cawley*, Westcot, Mme. Hoffer, Anna Ollivier, Mrs. W. J. Grant, France, etc., are always easy of culture. Of course, there are several Roses habitually addicted to come with quartered or divided blossoms, and no amount of care can prevent it. Such Roses should be banished, although it is only fair to say that the same Rose is not so defective in all counties. When pruning, cut back the current season's wood rather severely, and the out the plant so that the new growth may get the full benefit of sun and air.

Rose Marechal Niel as a bush plant (G. B.).—If you prefer a short standard Briar for this Rose, the bush or dwarf form will succeed almost equally as well, provided it be on a Briar root, or on its own roots, and planted in a good border. Splendid plants may be purchased, grafted on the Briar, that are specially grown for greenhouse culture. These usually have growths some 10 feet to 12 feet long, and, being well-ripened, prepared to give some good blossom the first season. The truth is to remember with this Rose is to give it a good border, be it indoor or in a cold-pantry, the Rose stems be protected from injury by frost, and the border covered over with corrugated iron or similar material to ward off superfluous moisture. Where artificial heat is not provided, we always advise planting this Rose inside, and a half-standard. This hedge Briar seems to possess more rooting power, a circumstance very desirable for a vigorous Rose as *Marechal Niel*.

TREES AND SHRUBS.

Arucaria falling (Monkey Puzzle).—As a rule, this soon presents an unhappy appearance, and is therefore, not to be recommended. It was killed in great numbers during the severe winter of 1890, and is no longer worthy of its popularity in the garden, being really a tree, of a climate quite different from ours. We fear we can do nothing to help your specimen, as it is apparently all but dead.

FRUIT.

The heaviest Gooseberries (A. Burns).—It is well-known that very fine fruits are produced for exhibition in Lancashire and Yorkshire, but this is only done by excessive thinning and special cultivation. We do not think the variety has so much to do with size as most think. We are not anxious to encourage Gooseberry culture for the production of huge berries, as it is better to produce the fruits in abundance for market or home use. Besides, the richest flavour is always found in those fruits that are relatively small, yet abundantly produced.

Pruning Vines (Heating Vinery).—You can prune your Vines at once. Cut off all the shoots on which the fruit has been to one eye or bud from the main stem. If you care to, you may leave two buds, and rub them weaker near where the Vines start into growth in the spring. If there are any insects in the house, you must wash down all the paint and glass, and also draw the rods with some insecticide. All you need do in the way of firing is to keep out frost, a temperature of about 40 degs. to 45 degs. being quite sufficient for your *Pelargoniums*, etc. Wrap something round the pieces of stem about that is exposed, otherwise frost may injure the Vine when the sap begins to rise. An old mat or piece of canvas will answer the purpose.

Manuring Apple-trees (H. H.).—In applying artificial manures to fruit-trees, especially those which like yours, are from three to ten years planted, and therefore have roots a long way below the surface, it is necessary to give a dressing fully double the quantity of manure that would be needed by vegetables or shallow-rooted crops. We usually advise the application of so much of these artificial per rod, and if you top-dress an area of 3 yards square about each tree, you should apply 3 lb. of the manure—viz. basic slag 2 lb., and kainit 1 lb., well broken and mixed, then lightly forked in. You can add with advantage 1 lb. of sulphate of ammonia in May. This is a dressing at about the rate of 1 1/2 lb. per rod, whereas for vegetables, 6 lb. would suffice. Apply the two last-named manures at once. Give Peas just the same. Turn the roots near the surface, one half the quantity would suffice. As it is, we fear the roots have gone deep.

VEGETABLES.

Caterpillars on Cabbages (Belle Isle).—The only remedy is to catch the moths before they deposit their eggs, which they do in the summer on the lower leaves, or handpick the caterpillars. Another remedy is to use fine salt, sprinkling it freely over the Cabbages in the evening, then washing it off the next morning with clear water.

SEEDT REMPLIS.

A. Wingrove.—See reply to "Davies" in our issue of Dec. 6, p. 524, re "Weeds in lawn."—*M. Brown.*—It is very difficult to advise without seeing the Vine. Ask the advice of some practical man in your locality.—*Edith Shirley.*—The Ivy will cling, but you will have to be careful by nailing it at first. The *Eunymus* must be exterminated from the wall. It makes a good wall covering.—*Caroline.*—We do not know any of the varieties of *Caroline* you mention, neither can we find the Rose in any catalogue we have.—*N. V.*—By reversing, you will find it very useful for striking cuttings and for placing it over the plants in which the cuttings are in a warm-house.—*Tracy.*

-We cannot undertake to name Potatoes.—*Paddy*.—See article in present issue, re "Lilium giganteum," p. 537.
 -C. A. Phipps.—The competition only closed on the 20th. Result will be announced in our pages in due course.—E. W.—No; keep the faggots out and substitute brick rubble or rough stones. The wood as it decays will only breed fungus.—*Mela*.—Not a gardening question.—*Mab*.—1, You will find a note dealing with "Raising Ferns from seed" in our issue of Oct. 19, 1901, p. 41, which can be had of the publisher, price 13d. 2, See note in issue of Feb. 15 of this year, p. 67, re "Raising Tuberosa Beronias."—W. E. Mason.—Try Amos Perry, Windmoore Hill, London, N., who showed the Poppies you mean.—W. Godfrey, Egmucuth, also showed Oriental Poppies.—W. J.—"V.M.H." stands for Victoria Medal of Honour; 3, You can fasten roses to the fence you mention, and they will, we think, take no harm, as the creosote will have soaked into the wood.—A. Burns.—See reply to "T. Maxwell," re "Increasing Clematis," in our issue of Oct. 25, p. 452. You will find an article on the best dark H.P. Roses in our issue of Sept. 20, p. 385. These numbers can be had of the publisher, price 13d. each.—A. L. Plumbridge.—You had better get someone in your neighbourhood who is used to such work.—S. O.—Cannot you manage to burn all the refuse you speak of, and not apply the ashes to the ground? If not, withhold the dressing of farmyard manure for one year, and give a good dressing of freshly-slaked lime.—B. E. Moore.—"The English Flower Garden," from this once, price 10s. 6d., post free.—*Guendolen*.—It will be advisable to leave them till the spring.—*Inkstand*.—1, The paint when thoroughly dry will not injure the plants. 2, Raise the pipes just off the ground on two bricks, taking care that the bricks have a solid foundation.

NAMES OF PLANTS AND FRUITS.

Names of plants.—*Bob*.—You have evidently got your names mixed. 1 appears to be Mrs W. Trafford, and 2, Charles Davie, badly grown.—*Belle Isle*.—*Helianthus scaberrimus* var. *Melish*.—*Sarnia*.—1, *Adiantum concinnum latum*; 2, *Adiantum concinnum*; 3, *Begonia incarnata* var. *maculosa*; 4, *Arecia* sp.—*Faircross*.—*Aparagragua plumosa*.—E. Seggore.—The Dittany of Crete (*Origanum Dictamnus*).

Names of fruits.—J. R. Huckleby.—1, King of the Pippin; 2, Northern Greening.—W. Wright.—1 and 2, Evidently small fruits of Northern Greening.—*Oxford*.—Small fruits of Ecklinville seedling. In sending fruit for name it is well to send really good specimens.—T. Brown, Burford, Oxon.—1, John Apple; 2, Manx's Codlin; 3, Adam's Pearmain; 4, Small's Admirable.

Rotting leather.—Will you kindly tell me if you can recommend any method by which leather scraps can be made to rot more quickly? I use a quantity of fine leather dust as manure, but large pieces can be bought more cheaply, and, if they can be made quicker in action by the addition of acid or other means, a considerable saving in manure bills would be effected. Should you be unable to give me any information, do you know anyone who could?—H. B. POLLARD.

THE HOLLY BOUGH

has already been marked for the adornment of the home, and paterfamilias is perhaps thinking of his last struggles with the sprays of shining leaves and glistening berries. But Mother is a trifle perplexed about the menu for the children's parties. As, however, Chivars' Jellies are sure to find a place in her list, she need not worry about the rest. The "Gentlewoman" says: "Chivars' Jellies are delicate luxuries." They are absolutely pure, and are favoured with ripe Fruit Juices. Ask the Grocer, and you will find he stocks them in various flavours in pint and quart packets. For a perfect beverage for the youngsters, Cambridge Lemonade is the thing. "It heals all." Chivars and Sons, Limited, Histon, Cambridge. First English Fruit Growers' Jam Factory.

CHARMING XMAS GIFTS.

CAMPBELL'S GENUINE COLUMBIA GRAPHOPHONES

and COLUMBIA RECORDS are the best in the World. Gained the Grand Prix, Paris Exhibition, 1900.

A Fascinating & Unrivalled Entertainer for the Home Circle.

YOU CAN MAKE YOUR OWN RECORDS

CAMPBELL'S Columbia GRAPHOPHONE

Is the best Talking & Singing Machine in the market. Special Xmas Price to readers of GARDENING, £2 15s. Carriage Paid, with 3 Records free. Sold only by Campbell and Co., Musical Instrument Makers, 116, Trongate, Glasgow. (Estab. over 50 Years.)

N.B.—Beware of worthless German imitations extensively advertised, which are mere toys.

The following are Campbell's leading cheap good lines in "C.I." TALKING MACHINES. (COUPON.)
 The "Lyra" Graphophone, with 2 Records, 1 15s. 0d.
 The "Gem" do. with Recorder & 2 Records, 1 10s. 0d.
 The "Favourite" do. do. do. 2 2s. 0d.
 The above sent carriage paid in Great Britain.

Beware of the German-made rubbish so extensively advertised by nondescript dealers. We are Musical Instrument Makers & Talking Machine Experts, and understand all about the goods we sell. 10,000 London-made Records to select from at 1s. each. Send for our New Price List for 1902 of all kinds of Musical Instruments and Talking Machines. Sold only by CAMPBELL & CO., 116 "A," TRONGATE, GLASGOW.

TWO GOOD GIFT BOOKS.

5/- each, nett. Post free, packed in box, 5/6 each.

The Amateur's GREENHOUSE.

By T. W. SANDERS, F.L.S.,

No. 73.—SPAN-ROOF GARDEN FRAME.

 4ft. by 6ft. £2 11 6 12ft. by 6ft. £5 12 6
 6ft. by 6ft. 4 2 0 18ft. by 6ft. 7 5 0

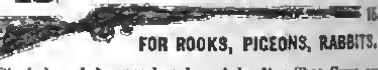

Patent Greenhouse BOILERS.

 The special merits of our Boilers are—
 1.—Long Burning.
 2.—Even Temperature.
 3.—No Trouble.
 4.—The Feeders being hinged can be pulled forward when desired, completely exposing fire-box.
 In these particulars our Boilers are beyond competition.
 Guaranteed Minimum Burning 12 Hours Without Attention.
 It goes without saying that the large reserve of fuel in the Feeder insures burning for at least four times longer than is possible with ordinary boilers. Unsatisfactory Boilers can be replaced in a few hours' work without moving existing pipes.
EXTRACTS FROM LETTERS RECEIVED:—
 "My gardener says he never had such a stove before, so easy to work, and does its work so well." "Does its work splendidly, and is certainly the least trouble of any stove I ever had." "My maids manage it." "The last No. 2 I had from you always goes 24 hours at a stretch." "I never look at it but once a day, and have a good even heat the whole 24 hours."

FRUIT. APPLE CULTURE IN S. WALES.

Years ago, I bought the following trees, selecting them myself the previous summer at local nursery: Two "Alfriston" and two New Hawthornden" (standards), one "Stirling Castle," one "Lord Sutfield," and one "Keswick Codlin" (bushes). Of the two last, after planting, I tied out all the side branches. The trees were by the side of the path, and I cut away all that were—as I may term it—behind them, as my idea was to form them into espaliers. When expanded some of them were 2 feet to 7 feet from one side to the other. I tried to bend one branch on Lord Sutfield, which grew right out from the front and snapped it nearly off. However, I did not like doing it, so, by chance, I stuffed some clay all round the break, and tied it up; to-day it is the best branch on the tree. The soil in this garden is a good loam, with clay about 15 inches deep. Before putting in the trees I was advised to place bricks and stones in the holes, and put the roots on them. This I did; I have carefully pruned these two trees every year. In July I cut away almost every new growth on two or three eyes—finishing in November—and I have kept extending and adding new shoots. The branches on "Lord Sutfield" number now seven on one side and eight on the other, and average about 9 inches apart, and measure 8 feet in length on each side of the trunk. This has bloomed well every year, and when the fruit has to be thinned before it is fit for use. The Keswick Codlin has eight branches on each side, and nearly all are 8 feet in length. This has never failed to produce a good crop. This year has been the worst; but a good picking. The trees of Alfriston I have not pruned at all. They only bear a good crop every alternate year, this being their good one. Stirling Castle I have kept well under with the scythe every year, and have not had one bad crop. This year, although it is only 7 feet in height, and about 4 feet through at the bottom, I have picked over a bushel, besides quite as many that fell. The New Hawthornden (one especially) has always cropped well. I prune these very little, only to keep them of a good shape. Last year on one tree I had some very large specimens—two were a pound each—and this year I weighed nine of the largest, and they turned the scale at 17 lb. Last November I bought at a sale in Cardiff six cordons. Apple-trees, which I planted—as I did the others—three on one side of the path, and three opposite on other side. My idea is to arch them over the path in time. They are only 15 inches apart. They were sadly knocked about in the sale-room and in their journey to me, but for all that I had sixty-seven fruits on the six-seventeen on Yorkshire Beauty, fourteen on Lady Sudeley, eleven on Newton Wonder, eight on Warner's King, sixteen on Lane's Prince Albert, and one on Peargood's Nonsuch, this one weighed a pound. I attribute the cropping of these to their being kept moist at the roots. I give them a good bucket of slops and soap-suds every week all through

the year, and in April manure-water, and never use the spade nearer than 4 feet from the trunk.

C. PERRY.

PEAR PITMASTON.

As regards size, I think this may be truly styled the king of Pears, for no other kind that I know can compete with it, given special treatment in its season of growth. In my notes on Pears (page 307) reference is made to some which in September of this year weighed nearly 2 lb. each. From this same tree I have in former years seen enormous Pears; in fact, the largest I can ever remember to have met with, if my memory serves me correctly, turned the scale at 3 lb. each. Now while the grower would naturally feel very proud of his marked achievement, many were heard to say, what is the value of such fruits? They certainly are not fitted for the dessert table, except as an ornament, which in substance was probably true; but who, it may be said, would not be proud of such giants could he point to the tree in his own garden which bore them? Judged from a quality point of view Pitmaston cannot be considered first-rate. There are many judges of fruit at autumn shows, who will pass over Pitmaston as being beneath their standard of quality. Even as lately as the third week of November this year, I overheard enstic remarks from milkers who criticised the judgment in a collection of Pears where this variety was included, and which gained a favourable position. Opinions differ widely in the matter of quality in Pears, and this, too, as affecting varieties usually above the average. I will give one case in support of this remark. A gardener sending fruit to the family who were away from home received a message complaining of the quality of the Pears he was sending. The variety was Burrell Superfin, and the fruits typical in size and maturity, and as I was privileged to try them myself I could vouch for their superiority. Its name certainly ought to place it above complaint. This and Pitmaston are two out of three so highly spoken of by your able correspondent, "East Devon," on page 548, one who not only grows Pears well, but who knows also what the points of a good Pear should be. I had never before heard a complaint made against Burrell Superfin as regards its quality. These 3 lb. Pitmaston Pears were the outcome of a course of irrigation, the water given being slightly diluted with drainings from a cow-yard. The natural soil was fertile, overlying gravel. The surface roots were preserved by a mulching of strawy manure, and the tree a young and healthy one.

NOTES AND REPLIES.

Grape Lady Downe's.—When at Bliton lately, I observed a fine lot of late Grapes. Lady Downe's was in fine condition, though the house is not in the best position for its growth. In former years Mr. Mayne has been troubled with mildew, but this year he resolved to give more air, closing the house much later in the afternoon. This has been productive of much good.—J. CROOK.

Pruning Plum-trees.—I have just planted some young Plum-trees (mostly Victoria) against a garden wall. They have each six or seven branches about a yard long trained fan-shape. The gardener wishes to cut them

all back to about 3 inches from the root. Is he right? Should they not be left as they are, to form the tree and rather encouraged to grow longer? I have two standard Plums, planted four years ago. They have flowered two or three times, but no fruit ripened. This summer a great many branches were a yard long. I cut them back a third of their length and trimmed the trees to balance them nicely. Could you kindly direct me how to prune the young trees the first few years?—HARR.

[Even if your Victorian Plum-trees planted against a wall had not been just planted, yet being young, and having to be pruned to make permanent trees, would have to be pruned somewhat hard. But when trees are newly planted and roots etc. of course, pruned, and reduced also, it is of the first importance that the lead or branches be reduced also, to make root and head equal. For that reason it is needful that the branches on them maintaining the season be shortened back to about 9 inches to 10 inches each, the weaker ones being shortest. Were the branches left as they now are, there would be poor root action, as the new shoots made from every bud would be weak. By cutting back to a few lower buds, these are induced to send out several strong shoots, and these react on the roots and cause them to make strong growth also. It is a matter of the first importance with young trees to cause them to become well established at the outset. With regard to pruning your standard Plum, four years planted, hard pruning is hardly the course to adopt to secure fruitfulness. These trees are now well rooted and carry good heads. The proper treatment for them, therefore, is spurring back weak inner shoots, those which break from the sides of the main branches, to two or three buds, and the leading strong shoots about one-third of their length—that is, of shoots 3 feet long, cutting them back to 2 feet. That removes points that may not be well ripened. Later, as the heads become larger, all that is needful is to keep the branches moderately thinned, leaving the shoots alone, as they will then be probably less strong. Very hard pruning of well-rooted trees tends to cause them to reproduce wood-shoots. Light pruning then induces fruiting, and fruiting becomes the best of all pruners.]

Fruit not ripening.—My fruit-trees, Pears, Plums, Peaches, and Nectarines, have been rather a failure this year, and the fruit has not ripened, although allowed to remain on the trees later than usual. I think they must require a change of treatment. Can you give the name of any manure or chemical likely to benefit them?—T. W., Hastings.

[Although the past summer has not been an ideal one for outdoor fruit in general, we have heard but few complaints as to the fruit not ripening properly, except in the case of very late Peaches, and the wet, sunless autumn would account for this; but in the matter of Pears and Plums we must look to some other cause. You mention about manures or chemicals, so conclude the trees are not so healthy as they should be. If this is the case, we would advise you to prick up with a garden-fork the top 3 inches of the soil the trees are growing in, and take out a trench 1 foot wide, 13 inches deep, 4 feet away from the bole of tree, taking every care of all fibrous roots, and replacing the former soil with good turfy loam, with a fair sprinkling of wood-ashes, bone-meal, and a little soap, with the addition of lime or mortar-

rubble for the stone-fruit. Make the soil quite firm, but do not undertake such work during wet or frosty weather. We could have advocated more drastic treatment of your trees, had fuller details been sent, so assume that they have given general satisfaction up to the past season. Crop lightly next summer, and endeavour to keep the trees free of insects, and if the trees show signs of improvement, you may assist them by giving manurial waterings two or three times during the growing period. A light sprinkling of guano or Thompson's Vine-manure occasionally, well watering them in, would benefit the trees. Avoid all this feeding if the trees show signs of growing too strongly, which they are not likely to under the treatment advocated above. Get the trees pruned, cleaned, and put in order, after seeing to the roots, avoiding treading much on the borders.]

APPLE PEASGOOD'S NONSUCH.

THIS is too well known to need a lengthy description. It is good for either dessert or cooking use, and is at its best early in November. It does best as a bush or espalier, while

Apple Peasgood's Nonsuch.

in cold localities a west wall would be well occupied by a tree of it. In some seasons the fruits colour grandly, when they have a noble appearance. The tree is inclined to grow strongly, so should be root-pruned every year or so, should such be the case.

EAST HEVING.

Curl in Peaches.—For the last few years the outdoor Peach and Nectarine-trees have suffered from excessive attacks of the disease known, I believe, as "curl." This appears now to be attributed to a fungus growth more than to the effect of cold winds. The trees here are on the south wall of a very sheltered garden, and are protected in spring by double folds of netting. They receive a wash of a mixture of sunlight soap, paraffin, etc., before the blooms show. There is usually a splendid show of bloom, and at first a healthy growth of foliage, but later the "curl" sets in and the trees become almost bare of leaves. Perhaps some of your correspondents may have discovered an effective preventive. I should be grateful to hear of any.—G. H. N.

Defoliating Vines.—The Vines I had in my eye at the time of writing had neither been hard-fenced nor heavily cropped. It was sim-

ply a question of two evils—either go without the Chrysanthemums or reduce the leafage—and I know more than one instance where the cultivator, in his anxiety to give his Chrysanthemums every bit of light, has reduced the leafage below three eyes, and this on Vines where the foliage was very green. I am far from believing that to reduce to three eyes when the foliage is fresh and green is good for the Vines. The best Grapes that I have ever seen and the largest-sized Vines were those on which the foliage was allowed to ripen naturally.—J. CROOK.

PLANTS AND FLOWERS.

INDOOR PLANTS.

NOTES AND REPLIES.

South African bulbs.—In your issue of GARDENING, dated Oct. 6, 1902, p. 416, you kindly replied to a query of mine, re "South African bulbs." You stated that the different kinds of *Cyrtanthus* do not require drying off. Please tell me if all the rest are to be wholly dried off, and the best temperature the year round?—JACK.

[As stated in the reply to your previous question two years ago, the different species

folia (which we had beautifully in flower in October in the warmest part of the greenhouse) should even in the winter be kept somewhat moister than the others, and in the summer it should be watered freely. In your previous communication you mentioned that a temperature of 59 degs. to 55 degs. could be maintained during the winter, and if such is still the case it will be suitable for all the plants you mention. The warmest part of the greenhouse is just the place for them, and as spring advances the day temperature may, with sun heat, run up to 65 degs. or 70 degs. or even more. By the middle of May fire heat may be discontinued till the cold autumn nights set in.]

Eucharis amazonica falling.—Kindly tell me the reason why the leaves of *Eucharis amazonica* die off so fast as they grow, so that there are only three or four in a 4-inch pot at a time? I am told the plants have many flowered. They are potted in equal parts loam and peat-mould, with a little sand (min. temp. 65 degs.). What heat do they require, also soil? Should they be dried off and when? Any information will oblige.—ARON.

[It is quite obvious on the face of it that your plants of above are in a low and weakened state. From your description, we imagine the bulbs have very few, if any, good root fibres attached to them. This is the main reason of the foliage failing to develop. These things are due to a variety of circumstances, though chiefly overmuch water and too little heat. It is in these conditions that the bulbs become a prey to the mite, and then it is almost as cheap to throw them to the fire-heap. Some years ago, however, we had just such a lot of neglected bulbs, nearly 2000 pots each 10 inches in diameter being quite full of bulbs, and hardly a green leaf upon them. These plants had occupied a front stage in a Gardening-house and apart from a very generous watering for the *Eucharis* alone, the plants came in for most of the moisture that in syringing fell from the Gardening. An examination of many pots revealed a very sour condition of soil, and being winter time, and no good loam available for repotting, other means had to be adopted. It so happened, however, that a long bed in a propagating-house was well supplied with bottom-heat, and no sooner was this realized than the whole of the pots of bulbs was quickly transferred. The pots were immediately plunged to half their depth in tan bark and fibre-refuse and no water was given to the roots. The pots were set down on a bottom-heat that rarely fell below 85 degs. Top-heat, meanwhile, was at 70 degs. to 75 degs., and a semi-moist atmosphere maintained. From the moment of introduction to this bottom-heat, the syringe was used at least three times each day, notwithstanding it was mid-winter. In a very short time one or two good leaves appeared, not weakly, but strong and permanent and of a good colour, and in six weeks the plants had so developed that three times the original plunging room was required for them. Perhaps the most remarkable thing in bringing this large and valuable lot back to health was the fact that in all those weeks the plants had never been watered at the root at all. The light spray of the syringe was all the moisture given, and the spray from it was so fine that hardly any water would travel to the bulbs. While we do not believe in bottom-heat where the bulbs are in good health, we have every reason to regard it as the best of means to bring sickly and poor plants back to health. This large lot had been kept far too wet and much too cold. Your plants appear in a similarly weak state, and we strongly advise you to do what is already stated, if you can. If you have not the bottom-heat, increase the temperature to 70 degs. and treat generally as follows: If no bottom-heat, raise the plants on pots so that the base of the pot is clear of the stage. Suspend all root-watering for several weeks, and until you have really fine foliage. Where no bottom heat exists the syringe must not be employed as we have stated above. The soil you mention is quite good and suitable, and we have little doubt your failure is due to too much root moisture and too low a temperature. In a temperature of 65 degs., very little water at the root is required at any time, but it is not a safe temperature by any means. Given a temperature of 75 degs., and the pots of bulbs—that is, the healthy plants—standing on open wooden stages, free watering is only necessary where

of *Cyrtanthus* do not require drying off during the winter, but, of course, as they are in a partially dormant state they do not need as much water as when growing freely; indeed, enough should be given to keep the soil fairly moist, but no more. We have several pots of *C. lutescens*, *C. McKoni*, and *C. parviflorus* that have been treated in this way in a structure where a temperature of 50 degs. to 60 degs. is maintained, and most of them are just now commencing to push up their flower-spikes, so that before January is out the earliest should be in bloom. Of the others, *Crinum Moorei* and *Bowiea volubilis*, both of which have large fleshy bulbs, will, unless they are in a particularly dry part of the greenhouse, not need any water till the commencement of February, and then only just sufficient to maintain the soil in a slightly moist condition till growth recommences. The *Gladiolus*, too, may be kept dry, while the following are all the better if the soil is kept slightly moist, not by any means wet, but just enough to prevent them becoming parched up: *Kempferia natalensis*, *Hemantthus natalensis*, *Hemantthus hirsutus*, *Littonia modesta*, *Gloriosa virescens*, *Sandersonia aurantiaca*, *Anoctanthus breviflorus*, *Begonia geranioides*, *Eucomis undulata*, and *Eulopia speciosa*. The *Stenoglottis longi-*

growth is rapid. With the foliage matured, much less water is required, and for a long period, but no actual "drying off" must ever be practised. A good rule is, that with a temperature of not more than 65 degs., root-moisture is not much required, and at this temperature the plants would be safer if not watered for a month. For growing plants, however, a temperature of 75 degs. is a much safer one, for it is not possible in these lower temperatures to gauge the degree of moisture, which less easy is it when the pots are associated with other things in the greenhouse. If you can follow the instance recorded here, you will be able to improve your plants quickly.]

FERNS.

BIRD'S-NEST FERNS (ASPLENIUM NIDUS).

These plants are easily grown into large and some specimens; their roots require good and careful drainage, because if this becomes clogged the chances are that the plants will grow up deformed fronds, which spoil theirauty, and render them eyesores instead of

australasienn will stand very well outdoors in the summer time if not exposed to the full sun. Great care should be taken to keep away slugs and woodlice, which are exceedingly fond of the young fronds. The best way to prevent these pests getting at the plants is by placing the latter over a pan of water on three inverted pots, so as to prevent the bottom of the pot touching the water, but at the same time leaving a liquid barrier of 2 inches all round to keep off all intruders.

WINTER TREATMENT OF MAIDEN-HAIR FERNS.

All the Maidenhair Ferns require a period of rest, and in none is this more evident than in *A. cuneatum*. Plants which have been growing freely during the latter part of the summer and autumn should be well exposed, and when the fronds are well matured the cooler the plants can be kept the better. If gradually hardened off and kept fairly dry, they will keep well where the temperature does not fall below 40 degs. Fahr., the fronds changing to the pale-green hue which florists prefer. It is no doubt owing to the fact that they have found

preferable. *A. elegans*, which has large and more spreading fronds, is now extensively grown. *A. scutum* is also valuable for cutting, the large spreading fronds being very effective and lasting longer than those of most of the Maiden-hairs. In the spring this makes a very pretty plant for decoration. The young fronds of plants grown in a light open position are prettily tinted. Of the smaller-growing Maiden-hairs, *A. mundulum* is the most useful. It makes a very compact and pretty plant, and the fronds are of a useful size for button-hole bouquets or any other purpose where perfect little fronds are desirable. In winter this requires some care, as it is much inclined to damp off. The plants should be stood up on pots and have sufficient room for the air to circulate among them, and in watering care should be taken not to wet the fronds.

ROOM AND WINDOW.

FLOWERS IN THE HOUSE.

PROBABLY more flowers and plants are required for decoration at this season of the year than at any other. For a fortnight before and as long after Christmas, there is a constant round of festivities of one sort or another. In order to make the most of everything some little ingenuity is necessary in the use of the flowers, whilst if it be frosty weather additional care is needed to preserve the plants, which are taken out of their growing quarters from coming to any harm. At such times it is an all-important matter to have a good supply of such plants as need not be afterwards kept for use another season. These can then be consigned to the rubbish-heap, save only sufficient to work up the stock another year. As much as possible plants of comparatively hardy constitution should enter into the arrangements so as to preserve others that are of a more tender character from injury. More depends upon proper care and attention in the preservation of decorative plants than is at times credited thereto, whilst in the use of cut flowers some considerable amount of forethought is necessary both in the selection and the disposition of the material at command.

FLOWERING PLANTS, ETC.—With nothing more than the average convenience of a well-ordered garden, it is possible to have Poinsettias of good quality, the old variety and *P. plonissima* (the double form) being the best late kinds. With a reserve for next year's stock it will not matter if a few of these do come to grief; this they will not do very quickly provided they are well-rooted plants and that they are not over-watered. Primulas, both single and double, are invaluable, but the plants should not be in large pots, those 4½ inches in diameter being quite large enough. The same applies to Cyclamens, except in the case of extra good plants, which may be used when in 6-inch pots. *Erica hyemalis* and *E. gracilis autumnalis* will be just in their full beauty; so also will the earlier of the Epacrises. These will all last well if looked after carefully. Turning to bulbs, we can obtain an invaluable supply from Roman Hyacinths and *Duc van Thol* Tulips (various colours), but notably the scarlet and the yellow. As decorative plants these should be kept as dwarf as possible, whilst 4½-inch pots will be far more useful than larger ones. Turning to berried plants, the most important as well as the hardiest yet in season are the Solanums, which if well established will stand well. Berried Aucubas will also be useful. Both *Rivina humilis* and *Ardisia crenulata* are valuable as a change in the form of berried plants.

Unsuitable vases for cut flowers.

—Those who have much to do with arranging cut flowers must have noticed how unsuitable many of the vases, etc., are for this purpose. Frequently one has to arrange large flowers in long, narrow receptacles. Many of them that are wide at the mouth taper to the bottom, so that only a few of the stalks can touch the bottom, and as only a few of the stems can reach the bottom, and as these generally hold only a small quantity of water, the flowers soon flag. A worse type is those with wide legs and bottom, with a narrow neck. Only recently I saw some 7 inches to 6 inches across

The Australian Bird's-nest Fern (*Asplenium Nidus australasicum*).

elements. The soil must be made sandy, and could consist of light turfy loam and peat, with some leaf-mould and good sharp sand.

A. NIDUS.—An interesting East Indian species, popularly known as the Bird's-nest fern, from the remarkably peculiar manner of its growth: produces entire fronds about 6 inches in length and 4 inches in breadth, which rise up from the crown, leaving quite a hollow centre at their base, formed by the fronds of equal breadth throughout, growing horizontally at first before taking up their upright course, thus leaving a large, open centre.

A. NIDUS AUSTRALASICUM.—This fine evergreen plant (here illustrated) is a native of New South Wales, and may possibly be only a variety of the preceding species, from which it differs greatly in its fronds being of larger dimensions and of an elliptic lanceolate shape, instead of being of a uniform breadth. Besides the above characters there is one point essentially distinct; the fronds, instead of growing horizontally at first, are produced all round the rhizome and take an upright direction at the first start, so as to leave the crown elevated and exposed, thus making the hollow centre more funnel-shaped. Although requiring more heat to grow and develop properly in winter the best part of the year, *A. Nidus*

the pale-green fronds so much more durable than the deeper green ones that the change has been brought about. For early spring use another batch of plants should be grown; these should be kept in cold-pits and as dry as possible without injury to the roots. They may then be started in warmth late in the autumn, and under fair conditions will make good fronds, and either for cutting from or as pot plants will come in for use about February and March. Like those for autumn work, these should be hardened off after the fronds are fully developed. It is useless to try to get good results from plants which have been kept growing throughout the year; the growth these will make during the last three months of the year will be weak and imperfect, and they will also have become so exhausted that it will be late in the spring before they will make any progress. All *Adiantums* should be kept moderately cool and dry at this season, and will then, if given a little more warmth, make good growth as soon as the days begin to lengthen. Where the pots are well filled with roots a little artificial manure may be given occasionally while they are growing.

A. cuneatum still holds first place among Maiden-hair Ferns for decoration, though several others which are for many purposes

at top and bottom, and in the centre not more than an inch wide. How is it possible to get enough stems into this space to make the vase look well? Much of the material made to hold out flowers is more ornamental than useful. Surely those who value flowers are not concerned with the appearance of the vases? If we can have nice-looking vessels and equally useful then there is a gain. The same may be said against a large number of the ornamental pots to put plants into. Vessels that are simple in make, with a broad base, and that hold a good supply of water are the most suitable.—J. CUMK.

OUTDOOR PLANTS.

ARABIS (ROCK CRESS).

WHILE the common *Arabis albidia* will always be found in cottage gardens and in market gardens where propagated in immense quantities every autumn, it will long also find a place in ordinary gardens not only as an early border flower, but also for growing on rockwork. For flowering, the green form is much better than the silver-leaved or variegated variety, though that too grows strong and flowers freely. If needed for its leafage, then the flowers should be gathered. But for edgings and especially for its foliage none are better than the close, compact, and almost rosette-like golden variegated, sometimes called *mollis variegata*. This should not be allowed to bloom, indeed does not do so much. The plants should be lifted and be replanted every October, both to have them very evenly placed and to increase the stock. The variety does not increase fast, but in a few years a very fine stock of plants may be secured. Once obtained it will be hard to lose if but ordinary care be taken to keep the plants safe.

HARDY FLOWER NOTES.

HELEBORUS MAXIMUS.—The giant-flowered Christmas Rose is undoubtedly the finest late autumn-flowering hardy plant we have. When conditions are suitable, one may have first-class blooms from the latter end of October up to January. I have at the present time

if the glass is shaded from the time the buds appear, the pink tinge will disappear. I think the flowers are most beautiful, as they expand naturally in the open air, but it is a pity to expose them to the influences of our uncertain climate. Cold winds, heavy rains, and snow destroy the beauty of the flowers, so that some provision should be made for sheltering them. Like all members of the family this variety loves a little shade during the hottest month of the year. It should be planted where the sun goes off by midday. Heavy, moisture-holding soil should get a liberal dressing of leaf-mould, and very light sandy soil should be enriched with good loam.

POLYGONUM BERNONIS is another autumn-blooming plant of considerable merit. It is in the way of some native Knotweeds, the foliage being dark green and carpeting the ground thickly. The flower-spikes, thrown up some 18 inches above the leaves, are rosy-pink, deepening in colour as the season advances, becoming quite crimson by the end of October. They are quite weather proof, heavy rains having no effect on them and autumnal frosts seem to intensify their brightness. This Knotweed should be planted where the underground stems can run without hindrance, and where the plant can remain undisturbed for some years. It is one of those things that do not care for frequent root disturbance. It likes moisture, but will do very well in a sunny position on light soil.

PLUMBAGO LAURENTE.—I made acquaintance with this plant some forty years ago, but can say that I have not seen it in really good form more than three times. It is by no means a difficult thing to cultivate, but it frequently disappoints, and comes in time to the rubbish-heap, especially in the colder districts of Great Britain. In the south of England the flowers do not begin to open before the middle of September. This season with me they were only expanding the first week in October, and are, therefore, liable to be cut off by hard frosts. It is, therefore, necessary to select a warm, sunny, well-sheltered position, so that the plants make an early well-ripened growth. This will hasten the formation of the flower-

time blossoming in a manner that affords the liveliest satisfaction. The fact of its blooming so freely outdoors at this season of the year, when flowers are scarce, and following so closely on the heels of the border varieties of *Chrysanthemums*, must be my apology for again calling attention to it.—A. W.

BLUE CUPIDONE (CATANACHE CERULEA)

(REPLY TO "PENTH.")

CATANACHE CERULEA (see illustration) is an old border plant, about 2 feet high, flowering

The Blue Cupidone (Catanache cerulea).

in summer. The flowers are a fine blue, and grows freely in corners and on margins of shrubberies. There are a white variety, which is as common as the blue, and a bicolor one. It is a native of Italy and the South of France, growing quickly in any soil, and is easily raised from seed.

DWARF PHLOXES.

IN the autumn of 1901 I planted a number of these attractive spring-flowering subjects in the rock garden. These blossomed in due course most freely, and have since grown into good-sized clumps, and give promise of a fine floral display next season. Each plant was set out in a "pocket" filled with prepared soil, the site for each being carefully selected, so that they would, when established, be able to display their trailing growths on and clothe the face of the rock forming the front of the "pockets." This they have done in a most satisfactory manner, and have largely assisted in hiding the inevitable bald appearance of newly-constructed rockwork. Among the varieties deserving of special mention are *P. amena*, a low-growing plant which is entirely covered with light pink blossoms early in May. *P. reptans* flowers later than the preceding, the colour being rosy-purple. It flowers quite as freely, but in habit of growth it is more loose and trailing, and does not form dense clumps. *P. subulata* has purplish-pink flowers with a dark eye or centre, and grows into a spreading mass not exceeding 6 inches in height. This flowered after the others were past their best, and is valuable, if only to prolong the season. *P. Nelsoni*, or *P. s. alba*, is a very effective variety having white flowers with pink centre, while *P. nivalis* is pure white, and flowers in the greatest profusion. This last is of very prostrate growth, and is, in fact, the dwarfest of all. *P. proemmensis* has pale lilac flowers, and sends out long, wiry, trailing growths, quickly hilling stones and rocks in their proximity. *P. frondosa* is another dense prostrate growing sort having light rose coloured flowers, and is a worthy companion to *P. amena*. The next two are more erect growers, and, although admirably adapted for growing on rockeries, are not so useful for the purpose named in the opening sentences of this note. One is *P. divaricata*, which has lilac mauve flowers, and the other *P. ocaia*,

The White Rock Cress (*Arabis albidia*). From a photograph by Miss Vaughan, Whittington Lodge, Worcester.

(Nov. 7th) plants carrying half-a-dozen good blooms, and they will continue to throw up until February. The pink tinge which distinguishes the flowers of this variety is very pleasing. In the open air this is very pronounced, the reverse of the petals being stained, but when the plants are sheltered by hand-lights the blooms come much purer, and

make note of it. To ensure good growth it is well to top-dress annually with leaf-mould or well-rotted manure. J. CUMK.

Wallflower Earliest of All. True to its character for flowering in advance of other varieties, this Wallflower is at the present

Original from the University of Urbana-Champaign

the colour in this case being deep rose, and is most effective. The individual flowers of both varieties are much larger than any of the above, and are borne in panicles, while the leaves are very large, compared with those of the trailing kinds, they being round at the base, and from about midway or half their length they narrow off to a point. These two varieties can also be employed for the embellishment of the fronts of flower borders with most satisfactory results. They all appreciate a light rich soil, and during hot, dry weather should not be allowed to suffer from want of water. On the approach of winter it is time well spent to afford the plants a light mulching of leaf-soil or, what is still better, Cocoa-nut-shire, which prevents frost and snow from injuring them to any appreciable extent, while it encourages roots to form wherever the growths come into contact with the soil.

A. W.

THE HERBACEOUS PHLOX.

THIS handsome plant, particularly valuable in the garden owing to the bright effect it produces during the summer and early autumn, between the seasons of the spring-flowering subjects such as Rhododendrons, Azaleas, Lupines, Delphiniums, and such-like plants, and of the autumn-blooming Michaelmas Daisies or Starworts, and perennial Sun-flowers, is, unfortunately, but rarely accorded the liberal treatment that its merits deserve. In the majority of gardens the erroneous impression apparently prevails that herbaceous Phloxes will succeed anywhere, and one consequently sees them languishing in shrubberies, barely keeping alive during hot, dry summers in unmanured, shallow beds, or struggling for existence in close proximity to plants of rampant growth whose far-reaching root-fibres absorb all the nutriment that should be reserved for the Phloxes alone. Such treatment is unworthy of such a decorative plant as the herbaceous Phlox, which, to be seen at its best, requires every whit as liberal allowance of food and moisture as do herbaceous Peonies and Delphiniums. In light soil this is specially imperative, and a heavy dressing of cow-manure should be placed at a depth of 12 inches to 15 inches, which will tend to keep the ground cool and eventually feed the roots, while, in filling up, the soil should be mixed with a good proportion of well-rotted hot-bed manure. In addition to this provision of rich food copious supplies of water will be needed in dry weather, for many of the Phlox roots are but just beneath the surface, and the upper rootlets soon shrivel if exposed to the burning rays of the sun day after day without being moistened. For this reason it is advisable to have the beds so constructed that the water does not run off them, but will sink into the soil. In heavy, holding soil these precautions are not so necessary, but even in this case the more liberal the treatment the more satisfactory will be the display.

Phloxes are far more ornamental in their effect when they are massed in separate colours so that they will afford breadths of one colour than if forms of varied tints are planted together, when they give the impression of a spotty medley of hues very different from the grand coloured-masses of crimson, salmon, or white which are provided when the former plan is adopted. Badly-coloured Phloxes of washed-out purple, dull magenta, and allied tints are often seen, but there is no reason why these should exist in any garden of to-day when varieties of the best colours are so easily obtainable. All dull or crudely-coloured forms should be banished from the garden, and none but the best introduced.

some hundreds, but the few here mentioned will be found good in their respective colours. *Red*: Coquelicot, vermilion suffused with orange; Etna, almost identical with the last named, but perhaps not quite so bright; Flambeau, large flowers of fiery orange-red. *Pink*: Baronne de Kessel Zeutsch, salmon-pink; Le Soleil, rose-pink, white eye; William Robinson, cerise-rose, crimson eye. *Purple*: Gretchenette, bright purple, white centre; Lord Raleigh, deep violet; Sesostria, violet-purple. *Lilac*: Escarmonde, soft lilac; Lucio Baitet, pale lilac-blue, white centre. *White*: Mrs. E. H. Jenkins, splendid white; Avdanche, Miss Robertson, very large flower, white with coloured eye; Madame Antoine Denis, white with crimson eye; Countess of Aberdeen, white with pink eye; Fille de l'Air, white carmine eye. In light soils herbaceous Phloxes may be planted either in the autumn or the spring, but in heavy soils spring planting is preferable. A mulching of rotten manure in June, and frequent waterings with weak liquid-manure from that time until the blooms are about to expand will increase the height of the flower-

niums. As far as it went my plan was very successful, but I quickly saw that my tubs had a "futuro" if managed with care and skill. The first winter the tubs, as seen from the house, were an eyesore when the kindly trails of Ivy-leaved Geraniums were destroyed by frost and then consigned to the rubbish-heap. The green paint, in all its hideous crudeness, could not be endured for so many months. The effect produced by several naked tubs was too artificial and formal to please anyone, and I therefore planted Ivy round them, and by the second winter the offending paint or form of the tubs could scarcely be seen. I had some of the beds turfed over and others filled with shrubs, leaving any Rose-trees suitably placed. Then I ennobly introduced two or three tubs, covering the sides with Ivy of different sorts, Ampelopsis Veitchi, Periwinkle, etc., keeping to ever-green creepers as much as possible for the sake of the appearance in winter. Ampelopsis Veitchi is, however, too beautiful in summer and autumn to be discarded.

The tubs can be kept bright and gay both in

Phlox Tapis blanc in Mr. Gumbleton's garden at Belgrove, Queenstown, Ireland.

stems and the size of the individual blossoms. Phloxes may be propagated by cuttings taken off the old plants in the autumn, these being the growths that shoot from the stem after the flower-head is removed, and kept under glass through the winter, or by those made after growth has started in the spring, which latter must be kept for a month or so in a frame before being planted out. Side growths appearing from the ground near the parent plant may be severed with good roots and soon make nice plants. Old stools may also be divided and replanted.

S. W. F.

THE GARDENING.

HAVING a flower garden too large for me to keep up in anything like good order with the limited amount of labour at my command, I began, two or three years ago, to brighten up neglected corners by tubs filled with flowers

spring and summer with very little care beyond watering. This is more than can be said for plants in a border, where a rat of water serves only to sprinkle the leaves, whereas the same quantity given to flowers in a tub goes home to their roots - no mean consideration this in a dry season. In starting the tubs care must be used. A surface of fine ashes must be first laid on the ground to keep out worms; then the tub, in the bottom of which at least a dozen holes must have been drilled, is placed in position, large crocks placed on each hole, and further a layer of broken crocks to ensure efficient drainage. On the crocks place a layer of rough, unscreened soil, so that the tub is filled to one-third of its depth, after which fill up nearly to the top with good garden soil, which, if possible, has been mixed with leaf-mould, silver-sand, and well-rotted manure. Unless the drainage be good and the soil well prepared and mixed you

will be disappointed in the quality and quantity of your flowers.

It would be beyond the scope of this letter to enumerate all the plants which may be advantageously used in succession in these tubs. Crocuses, Daffodils, and Hyacinths are amongst the bulbs which answer well; and close planting will give a better result. The brilliancy of a tub of yellow Crocuses peeping up in spring from what appears to be a clump of Ivy is very charming. At the end of May have your Zonal Ivy-leaved Pelargoniums, Heliotropes, Fuchsias, etc., ready, and after stirring up the soil when the bulbs have been removed, and reovating it by the addition of a little manure and any good compost, take the plants out of their pots and plant the Ivy-leaved Pelargoniums round the edge of the tub to allow them to trail down into the Ivy; then the Zonals, reserving a properly trained upright Ivy-leaved Pelargonium for the centre of the tub. Six Ivy-leaved Geraniums will be none too many for a tub, and the same number of Zonals. The arrangement of colours will be a matter of individual taste. A tub filled with Asters later in the season makes a good show, as also Stocks and many other annuals, which often fail in effect when scattered broadcast in a flower-bed. No one with any gardening capabilities at all can fail to secure brilliant patches of colour at a minimum of labour in gardens large or small. Ivy soon covers the tubs, starting off on its own account over the ground, and when it becomes too rampant is easily clipped into shape. The soil in the tubs during a dry season does not become so dry as might be expected, the Ivy or creeper outside helping largely to prevent evaporation. I cannot conclude without giving two pieces of advice. Hide the tubs by creepers as quickly as you can, forcing the growth by doses of liquid manure. Never throw away a paraffin cask, but have it sawn in half, and fill it with flowering plants. NIX.

Herts.

BOUARDIA LONGIFLORA OUTDOORS.

I do not think it is as widely known as it should be that this variety of Bouvardia can be easily induced to afford a great wealth of its beautiful white fragrant blossoms outdoors through the late summer and autumn months, and that without much trouble. Such is, however, the case, and the precaution is taken to select a site for the plants where they will be sheltered from the north and east, such, for instance, as a border in front of a greenhouse or a range of glasshouses. Here, if planted in a light, rich compost and afforded ample supplies of water during dry weather, they will thrive and make such growth as will astonish those who have not hitherto attempted growing them in this way, while from the middle of August until the middle of October—when they are best lifted and taken indoors—they will produce their trusses of long, tubular-shaped flowers in the greatest profusion. Of course, many will say we have an abundance of flowers at that period without troubling to grow anything so choice as Bouvardias, but although such may be the case, a border filled with them forms so beautiful and pleasing an object both to the eye and senses at the season mentioned, that if they could but behold them such objections would at once be dissipated. They give no more trouble in the way of labour and attention, and, in fact, do not require nearly so much care as many summer bedding plants, and all that is necessary is to keep them moist at the roots, and free from weeds by occasionally stirring the soil. A compost made up of loam, leaf-mould, and spent Mushroom dung in equal parts, with a liberal addition of river-sand or road-grit, suits them exactly, and in it the roots will ramble so freely that they can be lifted with balls of soil large enough to fill 10-inch pots by October. I use "cut-backs" for this purpose, and plant them in a border fronting a Peach house rather close together, so that they ultimately form quite a low hedge. Planting was done early in June, when the shoots were about 5 inches in length, and by the middle of August they had grown to such an extent that the growths were quite 3 feet high, and each plant 15 inches

through. Since then, although quantities of flowers have been cut for house decoration, the border has been quite a feature in the garden and has come in for a large share of admiration. The plants continue to afford flowers for some time after being lifted, if accorded warm greenhouse treatment. After they cease to bloom they should be gradually dried off and kept quite cool until March next, when they may be gently started into fresh growth, and finally hardened off so that they may be transferred to their summer quarters early in the month of June.

Most varieties of Bouvardias make excellent growth if planted out in the summer months; in fact, many gardeners grow their stock in this way for autumn and winter blooming, but none of them make such growth and produce such a profusion and continuity of bloom as does the variety under notice. Such a success has it been the past two seasons that provision for making a still greater display with it will be made between now and next summer. Those who are called upon to furnish an abundant supply of scented white flowers in late summer and autumn months should make a point of growing this Bouvardia on the lines indicated, and they will not, I venture to think, be disappointed. A. W.

HERBACEOUS BORDERS.

If evidence were needed to convince anyone of the superiority of borders of hardy herbaceous plants over summer bedding, one has only to learn a lesson from the past season. In not a few gardens where Pelargoniums, Calceolarias, Lobelias have helped to form the display, the dull, wet weather we have had has contributed to abnormal growth, with a falling off in bloom. On borders, however, where hardy plants have been, this has not obtained in anything like the same degree, and, generally speaking, notwithstanding much adverse weather, hardy flowers have been as plentiful as ever; indeed, in some respects the rain has proved beneficial, particularly in the case of Pyrethrums and Campanulas which were cut down after their first flowers. These furnished many useful blossoms in September, which one cannot always guarantee in a dry season. But now the glory of our herbaceous borders is past, and we are face to face with the season when planting may be done. There is pleasure to be found in a garden at all times—in the autumn, when the plants are resting, as well as in the summer, when their blossoms are on every hand. Just at present few flowers are to be seen, but now is the time to extend borders and enlarge one's collection. Specimens possibly we saw in bloom last summer will be added, clumps in our own borders that long have needed dividing will be dug up and split, and so the beauty of the garden will be further enhanced. It is a good plan to go over all herbaceous plants at this season and renew any labels that are nearly obliterated, so that during the winter there will be no possibility of our disturbing plants in mistake. One may instance Pyrethrums, Starworts, Chrysanthemums, and Phloxes that benefit frequently in being divided. We, doubtless, each have our own ideas as to the

ARRANGEMENT OF HERBACEOUS PLANTS.

It is nice to have as long as possible some flowers in the borders. In too many gardens there is a galaxy of blossoms from June to September, but in the interval there is an entire absence of bloom; but this need not be, having regard to the many that flower early and late in the season. We close the year with the Hellbore, whose blossoms open pure, even amid frost and snow. Why not augment the display by introducing one or two shrubs like the Winter Sweet (*Chimonanthus fragrans*), or the yellow Jasmium (*nudiflorum*), especially if we have a wall at our disposal? Then early bulbous things, as Aconites, Scillas, and Chionodoxas, will keep borders bright for many weeks. In the colour scheme of one's borders, too, it is largely a matter of taste. Pæonies, Oriental Poppies, or Kniphofias would not offend some if planted in close proximity to the walk, whereas others would consider them ill-placed in any other position than a distant one, where their tints are somewhat subdued. Again, one should, if possible, avoid having too many of the same colour in the border. What is

method and order should be manifest in every garden, one should remember that the best effects are not produced by endeavouring to grow every plant in a straight line. Some plants need full exposure to light to bring out prominently every detail, and some flowers with quiet tints need to be planted on the fore-front of the borders. With certain flowers their beauty is considerably enhanced when others intervene. It should ever be a question of harmony, and not of great contrasts. After all, what are really the happiest recollections of gardens we have seen? The blaze and garishness of some place where crude designs in carpet bedding exist for a time? I think not. Rather is it, to my mind, the garden where hardy plants bloom in succession, and come again year after year. WOODBRISTWICK.

NOTES AND REPLIES.

Agrostemma coronaria Walkeri.—This is a hybrid between *A. coronaria* and *A. flos Jovis*, and is a great improvement on both, the offspring having a neat, compact habit of growth, and possessing the good feature of lasting in flower until late autumn. The flowers open in rosy-crimson, and deepen in colour to purplish-crimson before fading, and a clump in full bloom can be seen a long distance off. The height is 18 inches, consequently it can be planted in the front row with telling effect. A. W.

Gaura Lindheimeri.—How beautiful and free flowering this has been during the past season. In fact, been in flower more or less since the middle of June, and only succumbed when cut off by the sharp frosts experienced the third week in November. All having a herbaceous border should make a point of growing it, not as an isolated plant, but in clumps, when they will be found self-supporting, or only needing four or five stakes and strings round the outside. It then rewards the owners with great quantities of spikes of the beautiful white and slightly rosetinted blossoms, and gives a long succession of them into the bargain. A. W.

Helianthemum.—Are these, in your opinion, worth sowing as hardy perennials, say in April next, and if they look well on comparatively small rockeries? I should get a packet of mixed seed. F. ALKXANDER.

[The *Helianthemum* is a plant of sub-shrubby habit, rather procumbent, and spreading freely. The blossoms are rather more than 1 inch across, mostly single, and appear several at the tips of the rather wiry stems. The plants are very hardy and true perennials. We should not be tempted to use them on quite small rockeries (there are so many better things), but on those of a rougher type in a less frequented part of the garden. Seeds of these may be sown any time during winter, and the earlier the better, for at times they are of uncertain germination. Any good seedsman will supply the seeds.]

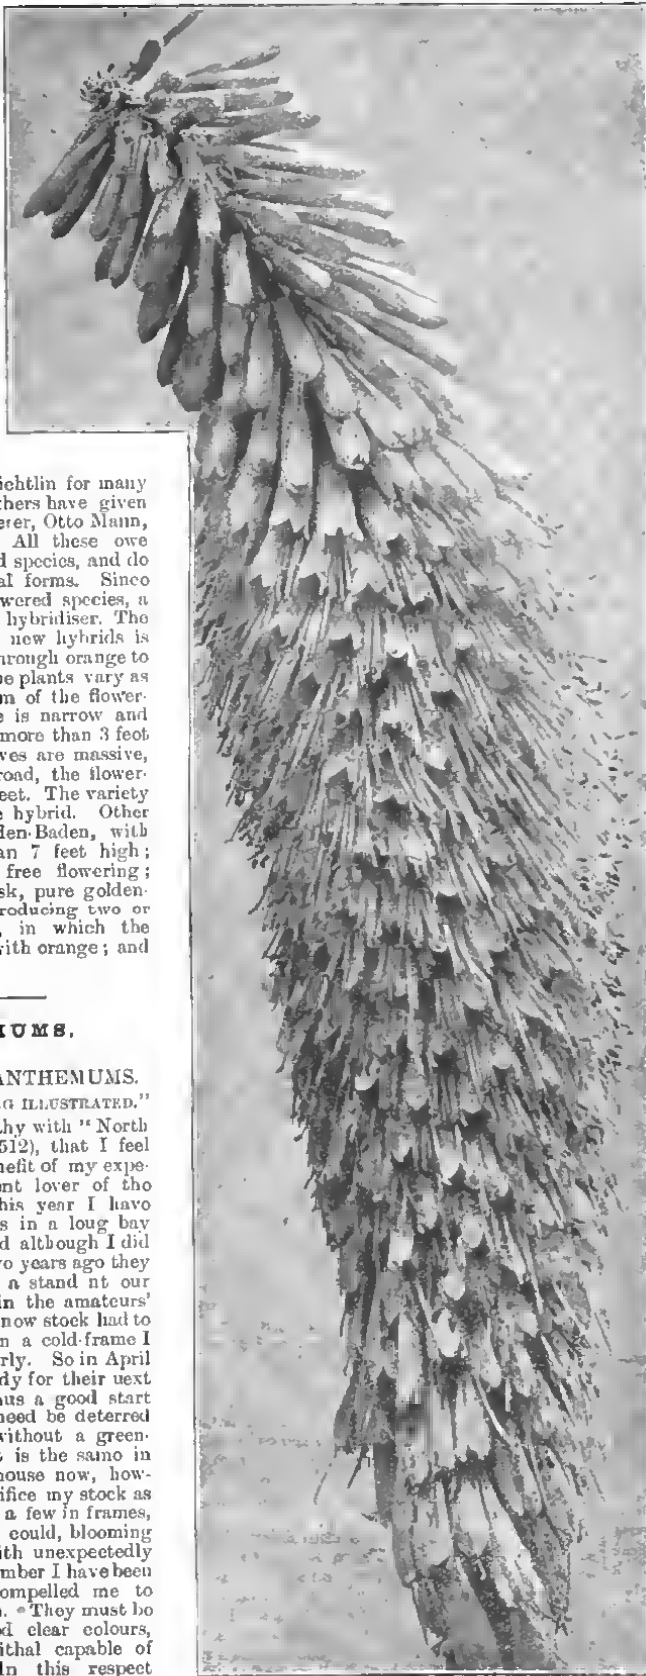

Treating seedlings of biennials.—I have recently bought "Hardy Flowers" (Wm. Robinson), the admirable clearness of the instruction in which renders it infinitely more valuable than the small sum (1s. 6d.) it cost me. I notice in the sowing of hardy perennials it favours the plan of leaving the seedlings in the seed-bed until autumn transplantation. Would you have the kindness to say if, in your judgment, this should be adopted in the case of hardy biennials, such as *Honesty*, *Cantabrigia*, *Bells*, and *Sweet Williams*? As you know, some authorities counsel these being transplanted once into reserve beds before being finally planted out. F. ALKXANDER.

[Exactly what is best to be done with all seedlings and with quick-growing plants in particular, depends on the seedlings alone, and especially as regards size and age. To keep certain things of naturally quick growth confined in the seed-pots or boxes for a prolonged period would, in not a few instances, mean partial ruin. This is due to the inability of the plants to develop afterwards. Seedlings sown in the open ground and quite thickly would not generally come under this head, and with the plants named, as *Honesty*, *Sweet Williams*, etc., by reason of the soft nature of the stems, these would take no harm. The same things in pots or shallow boxes would simply be starved if allowed to remain in such receptacles. An excellent plan with all these quick-growing subjects is to transplant when quite small into a prepared bed in the open, giving room for development, so that when the time arrives for transplanting to permanent quarters a good ball of earth and a tuft of roots provide us with a satisfactory material check.]

HYBRID FLAME-FLOWERS (KNIPHOFIAS).

LAST beautiful hybrids have, within the past few years, been raised, but if one only had the old Kniphofia Uvaria it is a plant capable of yielding very fine effects when planted in groups along with other suitable vegetation. All the hardy kinds do well in deep, well-drained soil. Once well planted Kniphofias form an effective mass of colour, and their beauty is visible at a long distance. A bold group of flame-flowers, backed or partly surrounded by amboos, is, in October, when in bloom, very effective.

We are indebted to Max Leichtlin for many of the hybrid forms, while others have given such varieties as John Waterer, Otto Mann, and Leichtlin, and others. All these owe their origin to the red-flowered species, and do not vary much from the typical forms. Since the introduction of yellow-flowered species, a new field was opened up to the hybridiser. The prevailing colour in all these new hybrids is now in all shades, varying through orange to crimson. In habit the plants vary as much as in the colour and form of the flower-stems. In some the foliage is narrow and deciduous, and the spikes not more than 3 feet high, while in others the leaves are massive, the spikes reaching a height of 7 feet. The variety figure to-day is a very fine hybrid. Other kinds are Star of Baden-Baden, with orange-yellow spikes more than 7 feet high; or, orange-yellow, very free flowering; or, deep yellow; Obelisk, pure golden-yellow, strong spikes, often producing two or three smaller spikes; Leda, in which the flowers are coral red tinged with orange; and Meteor, deep red.

Kniphofia hybrida Triumph. From a photograph by G. A. Champin.

CHRYSANTHEMUMS.

AMATEUR'S CHRYSANTHEMUMS.

THE EDITOR OF "GARDENING ILLUSTRATED."
I feel so much sympathy with "Northwood" (Nov. 29th, page 512), that I feel tempted to give him the benefit of my experience. I am such an ardent lover of the Queen, that until this year I have raised my Chrysanthemums in a long bay window facing south-west, and although I did "grow for exhibition," two years ago they were so good that I entered a stand at our garden and gained first prize in the amateurs' class. The trouble was that a new stock had to be bought every spring, as in a cold frame I did not strike sufficiently early. So in April I bought plants in 60's ready for their next year, and thus a good start was made. Indeed, no one need be deterred from growing a few, even without a greenhouse, as summer treatment is the same in all cases. I have a greenhouse now, however, so do not have to sacrifice my stock as a novice. I, of course, saved a few in frames, and cuttings, as early as I could, blooming plants in 6-inch pots with unexpectedly good results. The limited number I have been able to accommodate has compelled me to make a very careful selection. They must be of dwarf, strong habit, good clear colours, easy doers, and yet withal capable of producing large blooms. In this respect I am misleading to a novice a visit to a show. We see Mme. Carnot or Mrs. H. Weeks all their massive, yet chaste beauty. We do not know how many plants of each the breeder grow to obtain these grand blooms in time, or how he manipulated them. We then, with the result, probably, that the breeder produces a bloom like a "Catherine Wheel," and the other shows a bud on a set high plant about Christmas; if therefore I send a short list of such as I have found to

do well under ordinary treatment (do not translate this to mean spasmodic attention), and without scientific cultural knowledge. For whites, I head the list unhesitatingly with Miss Alice Byron, then Miss Nellie Pockett, Mrs. G. Henry, and Snowdrift. UN

believe Miss Elsie Fulton will prove an amateur's friend; it is exquisite. Good yellows are President Nonin, Lord Ludlow, M. L. Remy, and Mabel Morgan. Pink or lilac: Mrs. Coombes, Mrs. Barkley, Mrs. George Mileham, and Louise. Amaranth shades: M. T. Carrington and Millieent Richardson. Of dark varieties I have tried and discarded many. W. Seward is of a good colour but weak in the stem, John Shrimpton a strong-growing variety useful for decoration. In selecting a typical amateur's bloom I look for one which does not produce quilled petals too freely, or one in which the dark colour is inside and is lost. For example, the Hon. W. F. D. Smith, unless well grown, shows so many quilled petals as to look more golden than Ormiston. So also Lady Roberts. At a local florist's last week I saw a bloom on a dwarf plant of Violet Lady Beaumont, which seems just what we want; a large reflexing bloom, well filled centre, showing all the crimson, etc. I was assured it is a good doer. Having tried W. R. Church I can strongly recommend it. It will be noted I do not mention V. Movel and its sports, as probably every collection includes these standard sorts.

The foregoing is a limited list, but I have tried them all, and know their merits. Struck sufficiently early they will break naturally. If not, I pinch in early April for second crown bud. This puzzles a beginner, and I hesitate to mention "buds," so usually advise, if there is no sign of second break end of June or early July, to pinch again then, and a bud is sure to appear during August or early September in good time. There is such a chain for some in incurred that I advise all to try a few. Mme. Ferlat, C. H. Curtis, Hanwell Glory, and Fred Palmer are a range of colours and easy to grow. In conclusion, large blooms can only be produced on well-grown plants, no matter how good the variety.

ANNIE E. WHITEHOUSE.
Baball Heath, Birmingham.

LATE CHRYSANTHEMUMS.

I SHALL be very glad if you will kindly give me the names of the best late Chrysanthemums for market?—SUSAN JERRA.
[As the number of late kinds has increased considerably during the last few years, it is rather difficult to say which are the very best. I do not, however, see how L. Canning can be dispensed with. It is not quite so vigorous as could be desired, and florists complain that the flowers do not keep well, but one can always depend upon getting a supply of good blooms through January. Mme. Ad. Chatin is much in favour with market growers just now. It is of dwarf, compact habit, and the flowers are large and finely-formed. The late white of the future is probably Tuckwood White, raised from seed saved in Australia. As regards habit of growth, quality, and quantity of bloom it appears to be almost perfection, plants in 8-inch pots producing up to fifty good blooms. It is of easy culture, does not take mildew, and the blooms are almost damp proof. It would be difficult to name a Chrysanthemum endowed with more good points than this one. Boule de Neige is an old and very useful variety for cutting in December, but it cannot be relied on after Christmas. I cannot recommend it for the London markets, the blooms are too formal and not large enough, but in the provinces, where the standard is not quite so high, I should certainly advise a few plants being grown. It produces a large quantity of blooms, very pure and

worthy Rambler, Mme. Isaac Periere, Robusta, Parity, and Mrs. Anthony Waterer; and as bushes we can recommend the following as being hardy and suitable to your locality:—Grace Darling, Caroline Testout, Clio, Captain Christy, La France, Mrs. John Laing, Dr. Andry, Dupuy-Jamain, Ulrich Brunner, Gruss an Teplitz, Marie d'Orleans, Mario Van Houtte.]

Six Roses for pots in small greenhouse.—Kindly give me names of the best six pot-Roses to grow in house, span-roof, 12 feet by 8 feet, by 7 feet high. I want those that are continuous bloomers, rather small than large blooms preferred for cutting and buttonholes, and free-flowering. As the house is small they will require to be dwarf growers? Would Liberty, R. A. Victoria, Perle des Jardins, and Niphetos be suitable? Hints as to general culture will oblige. In winter I can keep house heated to 15 degs. to 50 degs. in severe weather.—G. H. S. USARINE.

[Liberty, Perle des Jardins, and Niphetos would be excellent. Three others we should recommend are Mme. Hoste, Mme. Jules Grolez, and Papa Gontier. This would give you a range of colour—white, yellow, pink, and crimson. Kaiserin Augusta Victoria is rather a late Rose, and being so very double, somewhat difficult to expand in midwinter, unless in great heat. It is a splendid kind, but one we could hardly advise you to attempt. Although you ask for pot-Roses, it is just possible, in this small structure, that you could prepare a bed in the centre, so that plants could be planted out. If this is practicable you would

ing directly they are pruned, and when new growths are just breaking give them a good watering. After this water very carefully, the syringing being almost sufficient moisture until foliage is well developed. If you commence by giving plenty of air both at side and top, you will have very little trouble with mildew, and the syringing with cold water on every favourable occasion will still further ward off this fungus, as it has a tendency to harden the foliage. Be on the alert for the first appearance of green-fly, and immediately fumigate the house. This must be done in the evening. You will find the plants will require from twelve to fourteen weeks to get them into bloom from the time they are pruned, but when growths are well advanced the plants will bear more forcing should you require them earlier. When flower-buds are seen tie out the growths to small sticks, in order to afford ample light and air to the foliage, and they may then have weak doses of liquid manure about once a week at first, then, as buds swell, twice a week.]

Rose La France de '89 (H.T.).—A magnificent Rose, marred by its absurd name, which misleads many individuals, they mistaking it for the old La France. The colour is brilliant red, flowers of immense size, drooping, and Prunus-like in form. To see this showy Rose to perfection one should plant it against

consequently you cannot cut these back as advocated above. An alternative plan in order to make the most of the growths now upon the plants is to leave them untouched with the knife, and when they start into new growth to rub off the bottom shoots, which will have a tendency to make them break higher up. The varieties upon the south wall will be all the better if the growths are cut back to about half their present length, but you must not do this until end of February or beginning of March.]

TREES AND SHRUBS.

TREE BORDERED WALKS.

In most gardens there occur spots either bordering or within sight of frequently used paths where, although the ordinary herbaceous border would be out of place, the informal grouping of flowering and fine foliaged plants would add greatly to the effect. Strong growing subjects of both kinds are eminently adapted for such places and where only partial shade is thrown by deciduous trees flowering plants may be massed with excellent results in the open spots. Serried ranks of white Foxgloves bearing aloft tall snowy spires have a charming appearance in such a site, and groups of white Honesty (Lunaria) are also telling. Great Maheins with grey-green foliage and towering yellow flower-spikes are noble plants, and the Flag Irises will give colour in the early summer, while in the spring, before the leaves of the trees expand, the stronger of the golden trumpet Daffodils will display their glowing yellow. Solomon's Seal is a graceful plant and succeeds under trees, especially if the soil be somewhat moist, and many of the Michaelmas Daisies appreciate partial shade. Beo Balm or Bergamot (Monarda didyma) is most effective when massed in a position where it can enjoy full sunshine for some hours of the day, and provides a breadth of rich crimson; while Campanula latifolia and its white variety, Geranium pratense, Centaurea macrocephala, Scabiosa elata, Bocconia cordata, Telekia speciosa, and other strong-growing perennials are well suited by the surroundings of the semi-wild garden, provided they get a fair amount of sunshine. Of fine foliaged plants we have the Yuccas, Acanthus latifolius, Heracleum giganteum, only suitable for a wild spot, the Globe Artichoke, a plant grand in form and soft in colouring, Silphium perfoliatum, the Compass-plant, Rhubarbs, of which one of the best is Rheum Emodi, Crambe cordifolia, Angelica, Funkias, Molospermum circutarium, and many others. Where paths lead from the well kept pleasure ground to the wild garden, the planting of their verges and surroundings should be arranged so as to gradually lose the appearance of formality until it merges into the absolute freedom of natural grouping. S. W. F.

Tree bordered walks. Engraved for GARDENING ILLUSTRATED from a photograph sent by Mr. G. P. Stanton, Townham, Gindfield, Sussex.

achieve greater success. It is surprising to what vigour such plants will attain when thus planted out, but you need not fear the kinds named would grow too high. Supposing, then, that you are able to make a bed for the Roses, the first step will be to remove the old soil to a depth of 2 feet 6 inches or 3 feet. Put in the bottom 6 inches of rubble, such as broken bricks, clinkers, or large stones. Then procure some turves, and place a layer of these grass side down. Fill up the remainder of the bed with good loam, two parts, and well-decayed manure, one part, adding about a 6-inch potful of 1/2-inch bones to each barrowful of the compost. This may seem rather an elaborate preparation for a few Roses, but we can assure you it pays best to begin well. You can plant out bushes grown in the open ground, but the very best would be those grown in 8-inch pots under glass be careful, however, to procure them on the Brier, unless own root plants are obtainable. The Manetti-stock is very useful for one season, but Tea Roses grafted upon it are very short lived, although they force better for the one year. If, however, you elect to grow the plants in pots, we should advise you to obtain these extra sized established plants in 8-inch pots. The treatment in both cases would be to prune moderately next month and keep house as cool as possible, provided no frosts enters, until new growths are about an inch in length. Syringe the plants every five morn-

a wall, for it makes quite a good climber. The foliage and growth are very distinct, and clearly prove it to be a Hybrid Tea. It has been particularly good this autumn, and I can recommend the variety as being one worth growing, especially where a showy Rose is desired. It objects to the Manetti as a stock, seemingly thriving best on the De la Grifferaie. Doubtless it would be a great success on its own roots.—R. S. A.

Pruning newly-planted Roses.—I have just planted the following Roses—Maréchal Niel, Niphetos, Gruss an Teplitz, Madame Lambert, Etoile, Climbing La France—out-oh a cool greenhouse and intend bringing the roots in and training over the roof. How and when should I prune them? Also the following on the south wall of the house—Sempervivum, Climbing Crazeville-Supérieure, Caroline Pillar, Bevoisensis, Mrs. W. G. Grant, Blaul No. 2, Crimson Rambler, Yellow Rambler, and various Ayrshire Roses.—BILLE ISLE.

[The varieties planted near the greenhouse with a view to bringing them inside would be best if cut back next March to about half their present length, but we fear with such kinds as Mme. Lambert, unless you have planted extra strong plants, you would be unable to bring the growths inside the structure. Such varieties as the last-named are excellent for climbing moderate heights, but when used for the purpose you have in view it is always best to make a border inside and plant selected pot-grown plants which have growths 2 feet to 3 feet in length. Of course, such kinds as Maréchal Niel, Etoile, etc., are pruned with growths some 3 feet to 5 feet in length,

Desfontainea spinosa grafted on Privet.—I looked eagerly for the answer and am disappointed, for you have, for a wonder, altogether missed the mark. I do not want "help" about the shrub—it is growing very well. What I called attention to was the fact of a great woody shoot of Privet growing out of its root stem, just below the soil, and then the Desfontainea bearing Privet flowers (in clusters, not spikes). Surely these two things are worthy of note? They seem to me extraordinary, and naturally the former just suggested the idea of grafting, as how else could it occur? I should be pleased to see some remark or explanation such as you often give to correspondents on things not wroo peculiar. I could not send specimens of both plants. I hewed off the Privet bough and am not aware that any other has grown out, as I have not seen it very lately.—M. A. II.

[It is quite impossible for us to form any correct idea unless you send us specimens of both the plants you refer to, but we do not think that the Desfontainea is grafted on the Privet.—Ed.]

Request to readers of "Gardening."—Readers, both amateur and in the trade, will kindly remember that we are always very glad to see interesting specimens of plants or flowers to be illustrated. We will kindly send them to our office in as good a state as possible. URBANA-CHAMPAIGN

VEGETABLES.

EDIBLE-STEMMED PLANTS.

Just now a plant of exceeding value, the Celery, is being largely consumed for its blanched and delicately flavoured, crisp-eating stems. Very soon we shall be employing the blanched stems of Rhubarb in tarts, stewed or otherwise, presented at table as a pleasant sweet. So, too, will be the white stems of the leafage of Seakale, a remarkably valuable winter product, also of Asparagus, which, if but partially blanched, gives quite delicious food. Beyond these, very nice for stowing, are the solid white stems of Leeks, when well blanched, and even the equally well-blanched leaf-stems of Chicory form delightful salading. When it is remarked that some of these vegetables can be had in gardens all the year round, and all are most wholesome food, we need not be too fearful of famine. Very recently mention has been made of an Australian Rhubarb now being grown here, that changes the order of the seasons and makes its stem growth naturally in the autumn and the winter. This is just as good a variety as is any of our summer Rhubarbs, and is called the Christmas Rhubarb. It is but needful to turn over plants of it in October tubs without tops or bottoms to protect it from frosts, and later, if the winter be more severe, to pack litter or Fern round the tubs, to keep the stems naturally growing. With ordinary Rhubarbs, if it be wished to have some early forced, a few of the strongest roots may be lifted, be put close together in a warm, dark place, with soil about the roots, and well watered; growth rapidly follows. But this should be done only where there is a large stock of roots, and some smaller or divided ones are put out into fresh soil every year to keep up the supply. Where roots are few, covering them up with tubs and a thick coating of warm manure and tree-leaves is the best way to force early stem growth. Seakale, a singularly useful stem plant, is easily produced in quantity. A sowing of seed thickly in drills, 2½ inches apart, in April, on good, deep, well-marured soil, the seedlings being thinned out to 12 inches apart, will give over 150 plants to the rod. If these be lifted in the winter after the leaves have ripened they will be found to have many side roots. These should all be cut off close to the main stem and be laid one way, then the main roots and crowns laid into soil thickly, ready for use, to blanch in a dark, warm place, and in soil during the winter, as wanted. Each root will give a good head of blanched stems, and when that is cut the roots may be thrown away, fresh ones taking their places. The root pieces should be made into cuttings 5 inches long, and be laid in thickly in the ground for the winter, the tops just covered with soil. There the tops and bottoms will callus over. Then they should be planted just as advised for the seedlings in April. Asparagus is best partially blanched by causing the stems to come up through some 3 inches to 6 inches thickness of soil, only the tender tops being greened. Leeks need treating as Celery is—that is, planted out into trenches, and as they grow earthed up. Then, when well blanched, the stems stewed are delicious.

A. D.

NOTES AND REPLIES.

Twin Cucumbers.—I enclose herewith as a curiosity a photo of a twin Cucumber, which grew in my garden this summer at Wingfield House, near Trowbridge. In one photograph I took it in the frame, in the other picked and held by the gardener. —(LADY) LILY V. CAYLAND.

[Twin fruits occur occasionally in all phases of Cucurbit culture. —E.]

Lifting Rhubarb roots.—I have about a hundred good roots of Rhubarb, which I intend to lift and force, and, as a constant reader of your valuable paper, should feel greatly obliged if you would kindly inform me, in an early issue of same, how they should be kept when lifted—if left on the ground in the open, or kept in the dry before being forced?—J. P. M., Tamworth.

[Lift the roots and place them under a wall or in some sheltered position, covering up with soil and some litter, so that, in case of severe weather, you can get them when you want to put any into heat for succession.]

Globe Artichokes from seed.—In severe winters these have suffered badly, and in many cases seed sowing has been resorted to for the production of stock. It is not advisable to obtain plants from seed if it can be

helped, as the seedlings are often so poor that it pays well to obtain suckers or offsets, even if the expense is much greater. The great objection to plants from seed is their inferior quality. Those who only have room for a limited quantity and are getting short of plants would do well to carefully detach the small suckers of this year's growth before covering up the plants. These may be potted up and kept in cold frames, and will make nice plants for spring planting if a small ball of earth is taken with the roots at the time of potting. Little water will be required during the winter.

Spinach in exposed positions.—How much better this vegetable stands severe weather if not coddled in any way and kept clean and thin. For early sowing in the spring a sheltered spot may be beneficial, but for the winter supply coddling is a mistake. A well-drained quarter is much better than shelter overhead. Of course, with winter Spinach more depends upon the time of sowing than upon the variety, as nearly every kind is hardy. It is the excessive wet combined with insect attacks at the root that often injures the plant. Sowing on firm land is of great advantage, the growth being hardier, the foliage thicker, and less liable to injury.

Moss-litter-manure.—Can you advise me how to make the best use of Moss-litter-manure in the garden? I tip it into a place about 6 feet deep and it keeps hot. My gardener complains that it heats too fast for hotbeds, and then goes off. I have about three of Oak-leaves, and a few Beech leaves. Would it be a good plan to mix leaves with it in the heap?—(Col. H. JONES).

[The better way to treat the above will be to mix the manure and the Oak and other leaves in layers, and with every layer of a thickness of 4 inches well water it. A better place than the pit, unless the latter is roomy, would be any open place that is rather lower than the general surroundings, so that the entire heap could be turned at least once every ten days. The great heat and the sudden subsidence of it are due to a lack of moisture in the heap. Mixed with the leaves, thoroughly moistened and incorporated, a steady and uniform heat suitable for hot-bed could be maintained for a long time. How long depends not a little on the making of the bed and, of course, the thickness also. Moisture, however, must exist in a degree sufficient not merely to generate the required heat, but with the subsidence of this to set up a process of decomposition also. Minus moisture the heart of a manure-heap will soon become a dry mass, impervious to further decay or greater warmth.]

Celery.—This is good this year, the wet season having suited it. The crop for late spring supply ought soon to be earthed up now, as much frost plays havoc with it, especially after a wet, mild autumn like the present, with the exception of a few frosty mornings the third week in November. A fine, dry day must be chosen; in fact, several days will be necessary on heavy soil ere such work can be undertaken, and it will be prudent to scatter a little lime between the plants, as slugs are abundant. Let this be the final moulding, as the plants make very little more growth from this date, smoothing the soil with the back of the spade so that rain will quickly run off.

The mild autumn and its effect on vegetable.—I do not remember in my gardening experience of over 40 years having seen the summer vegetables hold out so late in the season. This will do much to reduce the need for using roots, etc., giving a fine store of these, should we have a severe winter. I had a continuous supply of Peas from mid-June till the close of the second week in November. This arose from growing somewhat dwarf kinds on a rich, warm border, close by the glass-house. Runner Beans were sent to the dining-room on the 18th of November, and although these were late in coming into use in summer, this was compensated for by their lateness. The late supply was obtained from a sowing made on deeply-worked land at the end of the first week in July. Some may say this was too late to sow. I am aware it would be useless in a general way, but surely a small sowing is not ruinous, and certainly it is worth trying to continue the supply of this, the best of all Beans? New Zealand Spinach, again, has been most abundant, and helps to save the autumn-sown kinds in cold comers.

It is to be regretted this is not more grown, for no Spinach is so productive, and I never hear any complaints of its flavour. Now, 29th of November, I have many good patches under handlights. Nothing could be more satisfactory than the Autumn Cauliflower and the Self-protecting Broccoli. In early summer the plants made but little progress, but when their roots got down into the bottom spit, where the food was, they made headway, and produced enormous heads. When the cold began, middle of November, I took up all that were headed in and placed them together, heeling them into the soil, and covering with mats in cold weather. From these I shall have a supply till the new year. Lettuces have been splendid, both in my own garden and several others I have visited. Hicks' Hardy Cos I grow for autumn.—J. CROOK.

Green house for Tomatoes, etc.—I am going to build a greenhouse for growing Tomatoes and forcing Rhubarb and raising flower-seeds. The house will be 20-100, 14 by 9, 7½ at the back, and 4½ at the front. The tent will be half glass and half board, and I am going to heat it, having a flow and return pipe along the front. The house will face south and will have sun early and late. Do you think I shall be successful with it, and when shall I have to start Tomatoes for profit?—ESQUERRA.

[We have not the least desire to discourage your very laudable efforts in growing these plants for profit, but the number of plants you could grow in such a house as you describe will be very small. The only possible chance for "profit" at all in these days of overwhelming competition is that of ripe fruit in May, or even earlier. To obtain this the plants are already of fair size and in their fruiting-pot. This early-fruiting batch requires a good deal of heat in winter, and this would not be forthcoming from the amount of piping you intend putting down. Ifad the house had quite twice the amount of piping the necessary heat may, with good stoking, be forthcoming. In the circumstances you will be only able to get a summer crop. For this the seed may be sown in January or early February, in rather dry soil, keeping the house as warm as you can. As the seedlings come up and attain 2 inches in length, prick them off into pots, say, four in a 3-inch pot, placing them around the inside of the pot. If you sow the seeds at 1 inch apart in shallow boxes the plants could remain much longer before potting off. This is important, and many seedlings perish in the spring of the year, especially when made too wet. In your case your best plan will be to plant one row at the front and train the plants up near the glass roof. By taking up only the main root or vine you could plant at 1 foot apart. You may also fruit a few in 9-inch pots placed on the floor, not allowing more than four bunches of fruit to each plant. No shading whatever will be required for the Tomatoes.]

Artichokee—Jerusalem and the Globe.—The former, with me, has produced very fine tubers this season, owing probably to the frequent showers during the past summer. I still cling to the old purple variety, this being preferred to the white one recently introduced. If not already done, the growths should be cut close to the ground, and after taking up a supply for a week or so, and placing in the root-store, the quarter should have 3 inches or 4 inches of partly-decayed leaf-soil scattered over as a mulch, not that this tuber is likely to get spoilt by frost, but should severe weather set in the roots can be much easier taken up than is possible when the ground is frozen hard. The Globe, on the other hand, is often much damaged, if not actually killed outright, in some of the cold northern counties unless precautions have been taken to put up a reserve stock, keeping these in a brick pit, plunging the pots in leaves or coal-ashes, and covering the glass lights during much frost, but exposing the plants to full ventilation whenever the weather is favourable. It plunged as advocated, with an inch or so placed over the pot, no water will be necessary for the next two months. In warmer localities all that is necessary is to pack straw litter, Braeken, or fresh-fallen leaves well in among the old stools, putting a few forked or branched sticks around to keep the wind from blowing such protection about the garden. This should remain until March or until severe frosts are no longer the order. Some gardeners push it aside when a spell of mild weather sets in, but it is a tricky job.

as it may be overlooked when King Frost appears in earnest, and I do not find such protection do any harm during the next three months.—J. M. B.

GARDEN WORK.

Conservatory.—A little more pressure must now be placed upon the forcing department. Bulbs must be moved into heat. Double and single Narcissi that were potted early and have filled pots with roots may have a temperature of 60 degs. and be well supplied with moisture, with liquid-manure once or twice a week. If the bulbs are allowed to get too dry the flower-buds may die and wither without opening. The Italian Hyacinths in various colours are very useful, and come in soon after the Romans, which, though called Romans, are usually grown in France. The Bleeding Heart (*Dielytra*) forces well when thoroughly established in 6-inch pots. The roots of this plant can be bought very cheaply on the Continent, and though these imported roots will not force the first season, they will flower very well in a cool-house, and if hardened off and plunged out during the summer, they may be had in bloom early the following season. This is a very useful plant for the unheated conservatory. Tree Carnations are now very sweet and nice where well done. They must have the best loam mixed with a little very old manure and enough sand to keep the soil open and sweet. I do not care much for nostrums of any kind, but a dash of soot and a little bone-meal at the last shift will be useful. Free drainage and firm potting are necessary, and a light position when coming into flower; in fact, light in abundance is at all times necessary to obtain the best results. The Orange-tree has almost disappeared from the modern conservatory. It is sometimes found in old-fashioned places in the country, and very sweet and refreshing its fragrance is, and when the plants are large one can generally have blossoms and fruit on the same tree at the same time. The Orange is not at all difficult to cultivate. To grow good Oranges there must be warmth, but for decoration an ordinary greenhouse temperature will do. I think I have read somewhere that Orange-trees from seeds are more profitable to the Orange grower than grafted trees. Under artificial conditions, though Orange-trees are very easily raised from seeds, they are a long time coming into bearing unless grafted. But what a charming background to a large conservatory seedling Oranges would make, and some day they would flower and bear fruit in abundance. They should be planted in good loam and helped after they begin to bear.

Stove.—Heat and moisture will push things forward, but in cold weather it will be better not to waste the fire in securing high temperatures. Anything over 60 degs. may be considered a high temperature when the thermometer outside registers nightly 10 degs. or 12 degs. of frost. If it were possible to use covers outside the glass at night, it would save fuel, and the plants would be benefited thereby, as the conditions of growth would be more genial. When work is at a standstill outside, use the spare hands to sponge plants and wash pots in the houses. Stakes can also be prepared, but Bamboos and wood sticks can be bought so cheaply that, unless there are plantations of Hazel available, it will be cheaper to buy sticks, and labels also can be bought more cheaply than they can be made at home. Drainage material can be prepared for potting by-and-bye. This will save time when the busy season comes round. In the management of fires, flues and chimneys should be regularly cleaned. When flues around boilers are permitted to get encrusted with soot, some of the fire must be wasted. A good deal of fuel is wasted by having boilers too small for the work, or erring in making provision for sufficient lengths of piping where forcing has to be done. Gardenias and Eucharis Lilies will be coming into bloom now where the plants have been rested sufficiently before placing in heat.

Keeping Grapes.—When the bunches of Grapes in any house are much reduced in numbers, it would be more economical to cut the few bunches remaining, and place the ends

of the shoots in bottles of water in the Graperoom. Then the Vines can be pruned and the house cleaned, inside borders renovated, and the houses used for storing bedding plants, Geraniums, etc. Alicante and Gros Colman Grapes may be left on the Vines another month yet. The best temperature for keeping Grapes is about 45 degs.

Mushroom-house.—If the temperature falls below 50 degs. the Mushroom will not grow very fast—55 degs. is a suitable temperature for production, and in a well-constructed house this temperature can be kept up, except in severe weather, without fire-heat, but, of course, during frost fires must be lighted if possible, or production will cease. There will be a demand for Rhubarb, and relays of strong roots should be placed in the Mushroom-house. They will do in any corner, or in groups on the path. Rhubarb may also be forced in any warm structure. It comes best in the dark. The same remark applies to Seakale and Chicory, or Dandelions, which are useful for winter salads, and are not much trouble to produce.

Early Tomatoes.—Sowed a few seeds very thinly in pots or boxes in a warm house on shelves near the glass. There is plenty of good kinds that will set well in heat if treated carefully. The earliest crop is best grown in pots in a mixture of good loam and a little old manure and a sprinkling of bone-meal. Pot firmly, and leave space on the top for top-dressing. We have sometimes, when growing in less than 10-inch pots, run a strip of zinc round the top of the pot to hold the rich top-dressing. The young plants should be shifted on twice before the final potting into fruiting pots:—first into 3-inch pots, and then into 5-inch pots, and when these are filled with roots the days will be getting longer, and if potted into 9-inch pots and on the floor of a span-roofed house they will set and swell the fruit.

Win low gardening.—When severe weather sets in move the plants to the centre of the room over night and cover with several thicknesses of paper. Keep everything on the side of dryness at the root during frost. Plants wintered in the spare room should be placed upon an old carpet in the centre of the room and covered with paper. They will take no harm if covered for several weeks.

Outdoor garden.—Bulb beds should now be comfortable with a mulch of Moss-litter, manure, or something that will enrich the soil and shelter the young growth coming through. Hitherto we have not had much frost, and the Carnations that were planted in October, early in the month, have got fairly established, and will to a great extent be able to resist the lifting power of the frost when it comes. An inch or so of good loam on the surface will be a great help if it is free from wireworm, and after a frost of any severity a little pressure may be brought to bear round the plants to firm them again. All recently-planted things should be examined after frost and made firm. This is a suitable time to apply top-dressing to weak lawns. Quick-acting stimulants should not be given now, as the rains may destroy their effect before they have time to work. Bone-meal and basic slag may be applied now. Wood-ashes, garden rubbish, which has been charred, passed through a sieve, may with advantage be applied to lawns where the Grass is thin and weak, and something quicker in its action given in February or March. Soot is a cheap and useful manure, and 3 lb. of nitrate of soda per square rod will be effective any time in spring. Use the roller when the surface is soft, but it is possible to use the roller too much where the Grasses are weak and thin. It is necessary, for the sake of neatness, to remove the dead tops from hardy plants in the borders, though this craving after neatness may in some cases do harm by removing Nature's covering, in case of severe weather setting in.

Fruit garden.—Though the autumn is the best season for planting fruit-trees and bushes, there are often good reasons for planting later, and any time when the weather is open hardy fruits of all kinds may be planted, Strawberries perhaps excepted, as after the middle of November we prefer to wait until

February. Of course, the rooted runners are planted in a nursery bed and making roots, and will lift with balls, and may be moved any time in spring when the land is in good condition for planting. All Strawberry plantations not yet mulched may have attention at once. The Strawberry, under ordinary circumstances, is perfectly hardy, but sometimes, during the hoeing and cleaning in autumn, some of the surface roots may be exposed, and a top-dressing of manure is very beneficial now or earlier. There is still some pruning to do in many gardens, and though perhaps it may not be desirable to prune when the thermometer falls below 20 degs., there is no reason for stopping the work when the frost is not so severe, as when the earth is stiffened by frost the work can be easily done without treading the land into a quagmire. In the midland and northern counties Figs outside should be sheltered in some simple way during severe frost. The covering may consist of overgreen branches, which while sheltering the wood will not altogether exclude all circulation. New plantations of Raspberries should be cut down to within a few inches of the ground the first year to get established and make strong canes for next season.

Vegetable garden.—In frosty weather wheel manure on to the land ready for digging in when the frost goes. Trenching may be done, even if the land is a bit frozen, though it is not wise, especially if the land is of a clayey nature, to bury snow or frozen earth far from the surface. If weeds or decaying rubbish are trenched into the land, this should be wheeled on as soon as the frost sets in, and then the trenching may proceed, even if the frost is very severe. Jerusalem Artichokes left in the ground should have a covering of littersy manure placed over them, and the roots can be lifted any time as required. There will be a great loss among Cauliflowers and early Broccoli if the precaution was not taken to lift the plants with balls and plant in deep pits or trenches. But the wise man keeps an eye on the weather office, and when news arrives of cold weather on the Continent, no time should be lost in making things safe. As a rule, the low temperature reaches Germany and France before we feel it, and we have generally two or three days to get things in order ready for the low temperature when it comes. This is the time to make preparations for forcing various crops in frames on the hot-bed system. Get a heap of stable-manure and tree-leaves shaken together ready for beds of Potatoes, Carrots, Radishes, Lettuces, etc. E. HOBDAV.

THE COMING WEEK'S WORK.

Extracts from a Garden Diary.

December 2nd.—During frosty or bad weather generally, Pea-sticks are carted home and prepared for use. Bamboo canes are cheap now, and these are used to some extent, but young Hazel rods are even cheaper in country places, and are used for many plants, and in bad weather they are prepared and tied in bundles to save time in the busy season. This is a time, too, when plants in stoves and elsewhere are sponged with an insecticide to get rid of mealy-bug, if any are present, and there are not many collections of stove plants altogether free.

December 3rd.—Sowed seeds of Lobelias of several kinds. We do not altogether depend upon seedlings, but we want several thousand, and seedlings from carefully-selected plants are good enough. The seed-boxes are placed on a shelf in a warm-house. Cyclamens and Primulas are now making a good show of colour, and make pretty groups in the conservatory. We sow Cyclamen seeds early in August, thinly, in boxes, and keep the plants moving slowly in heat on shelves near the glass. Yearling plants produce the largest flowers.

December 5th.—There is always a lot of decoration to do at this season, and the demand for plants and cut-flowers is very considerable; good hardy Palms, especially Kentias, are the most useful for Christmas decorations. With a few good-sized Palms and Chrysanthemums, both of which are hardy enough to last for some time, the tender things can be kept in the houses for use at another season. Among hardy things which may be grown in pots, we

find many of the Japanese shrubs very useful. Moved bulbs, Spireas, and Rhododendrons from cold-pits to house.

December 20th.—Vaporised Cucumber-house, as a fly or two was noticed. The Cineraria-house also was vaporised at the same time. Bahay nights are selected for this work. Mixed a lot of stable-manure and leaves together in a heap, ready for making hot-beds. Cut the remainder of the Hamburg Grapes and bottled them. Pruned the Vines. Shall get the Vines washed, the house cleaned, and the borders top-dressed, as the house will be used for storing Geraniums.

December 21st.—All spare time is devoted to trenching vacant ground, preparing manure-heaps for wheeling on the land in frosty weather. Fig-trees on walls have been sheltered with Spruce branches. Night temperature in pot-Vine-house is 50 degs. at night; bulbs are swelling. Early Peach-house, 47 degs. Cucumber-house, 43 degs. No air is given now to Cucumbers, and a little warm compost is scattered over beds occasionally. Potted more French Beans, which are brought on on shelves near the glass wherever there is room in warm-houses. Mushroom-house, 53 degs.; beds are covered with hay to keep in warmth and moisture.

LAW AND CUSTOM.

Nature and conditions of tenancy (S. S. G.).—It is very difficult to give you an answer without referring to the facts, but in my opinion the usual rule does not apply, and a jury would be directed to find that you held under a yearly tenancy, without any agreement whatever except as to rent. Neither your landlord nor yourself would be bound to do the repairs (if such become necessary) to which you allude. The tenancy would be determinable at the end of any year of the tenancy by either party giving to the other half a year's notice for that purpose. In such a case as this it was most unwise to leave any of the terms or conditions of the tenancy "in abeyance," as it becomes an open question whether the proposer of the conditions, etc., did or did not actually waive or withdraw them. My opinion on the facts stated is given with considerable diffidence.—K. C. T.

Trespassing sheep.—My garden and my neighbour's garden run parallel to a Grass field occupied by a farmer, my neighbour's garden being between the field and my garden. The farmer's sheep passed through the dividing fence and entered the garden, and did much damage to my crops, but, practically speaking, did not injure my neighbour's crops. This was not the first time the sheep had been out, and when I remonstrated the farmer merely said he did not want to be troubled about the matter. On this last occasion the sheep destroyed a whole bed of Cabbage plants, which cannot be replaced, and it was about ten o'clock at night when I found them in my garden. It was useless to drive them back into the farmer's field, as they would return again to the garden, and as his premises are 15 miles distant, it was impracticable to take the sheep there at that hour, so I drove them into a private road near and left them there. The next morning my neighbour told him what had been done. He never came near me, and after a week had passed I wrote to him, telling him he ought to have come and offered me some compensation, but he replied that I should have gone to him. I then said that if we could not settle the matter I should sue him for damages. Will you tell me the proper procedure to commence an action in the county court to recover damages? What expenses will be incurred? Must I employ a solicitor? Can I recover the full value the Cabbage plants would have possessed next spring, or is my claim limited to the cost of the seed and the labour of preparing and sowing the ground? Was I bound to drive out the sheep, or should I have let them till the farmer came for them? Can he sue me for driving the sheep into this private road?—R. B.

[The first question that arises is this: To whom does the fence between your neighbour's garden and the field belong? If it belongs to the farmer, there is no question as to his liability to you. But if it belongs to your neighbour, then it is a question whether your neighbour is bound to maintain the fence against the farmer's stock? If he is so bound, your neighbour is the person responsible for the trespass of the sheep, and you should sue your neighbour. If, however, your neighbour is under no obligation to maintain a fence against the farmer's stock, the farmer is liable to you in damages. If you wish to enter an action against the farmer, you should make up your mind what sum you will claim as damages, and you may then go to the office of the registrar of the local county court and simply state that you wish to enter an action to recover damages

from the farmer. The registrar or his clerk will fill up a plaint note and give you any instructions that may be necessary. You will be charged a small sum for the entry of the plaint, the amount of the charge varying with the amount of damages claimed, and if the case goes to trial you will have to pay a further charge (poundage) when the case comes on, called the hearing fee. It is unnecessary to employ a solicitor, but it may be advisable to do so if there is any dispute about the liability to maintain the fence. The measure of damages will be the actual pecuniary loss to you plus a further sum for annoyance; it will not necessarily be the probable value of the Cabbages next spring, because you may be able to put the land to some use in the meantime, but the damages will not be confined to the cost of seed and labour. You were not obliged to remove the sheep from your garden, but you acted properly in removing them. As you know to whom the sheep belonged, you were bound not to put them in a place of peril; it seems, however, that they sustained no injury in the road, and so their owner has no cause of action against you, but the owner of this private road might sue you if he chose.—K. C. T.]

BEEES

Preparing wax from old combs (J. B.).—By the use of the wax extractor all the waste and trouble incidental to the various old-fashioned processes of preparing wax are avoided, and by the improved method the wax produced is of a good colour, and free from all impurities. The extractor consists of an outer tin cylinder, very much resembling an ordinary potato steamer, having a tin dish inside, provided with a spout. Between the dish and the outer cylinder the bottom is pierced to admit steam. A basket of perforated zinc fits over the tin dish. This basket being filled with old combs, the whole is placed over a saucepan half filled with water, and put on the fire. The steam passing through the perforated zinc, melts every particle of wax, which oozes through and drops into the dish, and through the spout into a basin or other receptacle, which has the inside oiled, and contains about 2 inches of hot water to keep the wax from adhering. If an extractor is not used the combs may be put into a clean saucepan, with as much soft water as may be necessary to prevent the wax burning. Place the saucepan over a slow fire, and stir occasionally until the combs are melted, then strain through a fine canvas bag into a tub of cold water, laying the bag upon a piece of smooth board of such a length that one end will rest at the bottom of the tub. Then compress the bag of hot wax with a wooden roller; the wax will ooze through and run down the board into the cold water, and set in thin flakes upon its surface. When all is finished collect the wax from the surface of the water, put it again into a clean saucepan, with a little water, and melt very carefully over a slow fire, taking off the scum as it rises. When sufficiently melted, pour it into wetted moulds, and let it cool slowly to avoid cracking. Still another way, where a large quantity of comb has to be melted, is to put the broken-up combs into a copper, pressing them into as small a compass as possible. Then cover a wooden hoop, the diameter of the copper, with cheese cloth, which place over the combs, keeping them down by weights. The copper being nearly filled with water and brought to boiling point, the wax separates from the refuse and rises through the cheese cloth to the top of the water. When cold it can be taken off in a solid mass, remelted, and poured into moulds.—S. S. G.

BIRDS,

The Brambling Finch (Fringilla montifringilla) (F. L. O. J.).—This handsome bird is a winter visitor to this country, being a native of the mountain districts of the northern regions of Europe. Although it seeks its food in wild districts, feeding on Beech-mast and the seeds of Grasses, in severe weather it visits the lowlands, where it may be seen in small flocks, frequently in the company of Chaffinches. The Brambling is a favourite as a cage-bird more on account of the beauty of its plumage than for its talent for song, although in the spring

it utters a pleasing warble. The male of this species in his summer plumage is a very elegant bird, the head being black, the chin and throat orange-fawn; back grey and black, beautifully scalloped; wing-coverts black, tipped with fawn, while bars of yellowish-white cross the wings; the tail black and somewhat forked. In winter its plumage is not so bright, and the black on the head is mixed with yellowish-brown. It exceeds somewhat the Chaffinch in size, being 6½ inches in length, of which the tail measures 2½ inches. The hen is somewhat smaller than the male, and is duller in the tints of her plumage, which does not vary throughout the year. The young resemble the female in plumage. Although this bird does not readily become tame in confinement, nor easily accustom to its surroundings, it will, with proper care and attention, survive many years. It will eat all kinds of seeds, but Hemp must be sparingly supplied, as this seed has a tendency to cause over-fatness. In its wild state the Brambling adds insects and berries to its diet, and in captivity will enjoy better health where a like variety of food can be supplied. These birds seldom breed with us, but on their return to their home in the far north construct their nest in the fork of a Fir or Birch—a handsome structure composed of Moss, Lichen, bark of the Fir-tree, and lined with feathers and wool. The eggs are of a greenish tint, spotted and streaked with reddish-brown, and are usually five or six in number. A good-sized cage should be provided for this bird, for, being of a restless nature, it likes plenty of exercise.—S. S. G.

POULTRY.

Ducks (L. J. G.).—It is safer not to allow more than three ducks to one drake if the eggs are required for setting. In its wild state the duck pairs with a single mate.—S. S. G.

Breeding Hamburgs for show.—There are several varieties of this family, which are known as the Pencilled, Spangled, and Black, with the sub-varieties of Gold and Silver in the two former. The Black is the largest, and produces a greater number of eggs than either of the others, although all are excellent layers, the fact of their being non-sitters allowing them more time than most breeds for egg-production. The best to breed up for show form is the Golden Pencilled. To insure success, however, it is important that the stock birds be judiciously mated by crossing a cock of a deep red-lay with hens of a rich golden lay. The male should have a short back and prominent breast, and be held in carriage. The comb should be large, even in shape, and gracefully tapering to a point at the back, and firmly fixed on the head. An important point is spotless white ear-lobe. These should be smooth, and as round in shape as possible, legs moderately long and slate-blue in colour, neck arched, and covered with an abundant lackle of a rich, deep bay colour. The tail should be full, with long, broad sickles, and carried rather upright, but gracefully, while the side tail feathers should also be arched and in keeping with the sickles. The feathers of the tail should be black, and the sickles and side feathers evenly edged with red-brown sharply defined. The head, lackle, breast, saddle-lackle, and thighs should be of a deep red-lay, without pencilling or marks of any kind. The inside web of the flight feathers should be black, and the secondaries barred with black, every separate feather having a black spot at the end. The under parts of the body should be covered with brown-red plumage, every feather being pencilled or barred with black. In the hen the lackle of the neck must be a clear golden-bay, and the whole of the remaining plumage of the same colour, but each feather evenly pencilled with black, the markings being as clear and distinct as possible, and appearing to stand out from the ground colour. The comb should be neat, firm, and small, square in front, and tapering to a spike at the back, and having the appearance of a piece of coral, with numerous small spikes throughout. The wattles should be small and well rounded. A well pencilled tail is often difficult to obtain, while the breast frequently proves very faulty in its markings. Spotted luckles are also great defects, although very common.—S. S. G.

CORRESPONDENCE.

Questions.—Queries and answers are inserted in GARDENING free of charge if correspondents follow these rules. All communications should be clearly and concisely written on one side of the paper only, addressed to the Editor of GARDENING, 17, Furnival-street, Holborn, London, E.C. Letters on business should be sent to the PUBLISHERS. The name and address of the sender are required in addition to any designation he may desire to be used in the paper. When more than one query is sent, each should be on a separate sheet of paper, and not more than three queries should be sent at a time. Correspondents should bear in mind that, as GARDENING has to be sent to press some time in advance of date, queries cannot always be replied to in the issue immediately following receipt of their communication. We do not reply to queries by post.

Naming fruit.—Readers who desire our help in naming fruit should bear in mind that several specimens at different stages of colour and size of the same kind really assist in its determination. We have received from several correspondents single specimens of fruits, naming, these in many cases being unripe and otherwise poor. The difference between varieties of fruits are, in many cases, so trifling that it is necessary that three specimens of each kind should be sent. We can undertake to name only four varieties at a time, and these only when above directions are observed.

PLANTS AND FLOWERS.

Cinquefoil (Potentilla) (Potentilla).—The double Potentilla are very showy, lasting in perfection, both on the pots and when cut, longer than the single sorts. There is a great number of named kinds, all of which can be obtained from any of the large hardy plant nurseries. See represent every shade of size and colour that it is possible to obtain. Potentilla luxurians in a light, deep soil and exposed position.

Propoleum tuberosum (M. H. Maurick).—This tuberous-rooted climber from Peru, with slender stems set to 12 feet high, and bearing in summer a profusion of its scarlet and yellow flowers. It should be grown in pots on the poorest of soils, allowing its branches to hang the ground, or supporting them in some way. It is not hardy in all soils; it is desirable to lift in the autumn, store in a dry place, and plant out in the spring.

Mistle for greenhouse (B.).—If your oil stove heats the plants dry, it is clear you do not manage it rightly. To have the water too high will cause a nasty all and a sooty settlement upon all the occupants. If low, you burn just as much oil, and again get an aromatic and nasty smell. Quite a small stove should do a house 5 feet by 6 feet. The question of wooden is immaterial.

Setting bulbs (J. P. T.).—It is getting very late, yet you still put up Hyacinths, Tulips, Narcissus, etc., setting them in Co-pas-beds or ashes until the pots have one well filled with roots, and placing them in heat as I want them. The temperature you give is too high, as it will draw them up and spoil them. You will find an early dealing with the culture of Narcissus in *Jardinier's* for June of May 25, 1901, which can be had of the publisher, price 13d.

The Scarlet Clematis (C. coccinea) (Woodhouse).—This is a distinct and beautiful species. Its stems grow from 6 feet to 10 feet high, and, as a rule, in a country die back to the ground in winter. It is a native of Texas, the flowers varying in colour from rose to scarlet. They are swollen at the base, but run towards the top, as it is never, the tips of the petals are recurved. These sepals are very thick and set a lethargy and catch over an inch long. We have figured it.

Twenty good standard Roses (Worcestershire).—The following are all good and proved kinds: Courard F. ter, Caroline Testout, Charles LeFebvre, Dr. Andrey, Prof. Jamain, Duke of Edinburgh, General Jacqueminot, the Duke of Devon, Grace Darling, La France, Mme. Lambert, Mme. Cochet, Marie Van Houtte, Mrs. John Laing, Mrs. G. Sherman Crawford, Souvenir de S. A. Prince, Ich Brunner, Viscountess Polkstone, White Maman hat, and William Allen Richardson.

Darguritis Carnations falling (Manzmann).—It is not the least doubt you have been keeping your plants too moist and close, not allowing sufficient air to the plants cool and free from damp. To cultivate carnations well, you must always stand them where the air circulates freely among the plants. The fruit stage of your carnations would be very suitable if you could get a great ventilation. It is a mistake to place among plants, as they are sure to damp off owing to the heat arising from other things.

Rose Xavier Oilbo (Woodhouse).—This is not all a good Rose for the novice to grow. It is of a very beautiful colour, and when seen at the Rose shows a splendid bloom, but its growth is so weak that unless it can be added annually it is not worth the trouble to cultivate. A good rich land, if budded on the Brier and allowed to remain where budded without transplanting, this and a number of other bad growers succeed fairly well for a year or two. The following are first-rate dark Roses, and can be depended on to grow well—namely, Abel Carriere, Baron de Fontenay, Charles LeFebvre, and Prince Carulle de Rohan.

Foxgloves (Rorie).—No, they will not bloom in the manner treated as you say. The seed being so small is best sown in pans or boxes under glass early in May. When the young plants are well up, they should be placed out-of-doors to get thoroughly hardened before being put to their flowering quarters. It is always advisable to sow some seed annually, and if seed is plentiful, scatter it in woods or coppes where it is wished to establish the plants. Self-sown seedlings come up everywhere in the neighbourhood of a flowering plant, and in many cases such seedlings are the best, being strong and vigorous.

Chrysanthemums on single stems in 1-inch or 7-inch pots (An Old Reader, Walthamstow).—The varieties, which we give in detail in another paper to a question of yours, may be treated as follows: Those in the first of the three series should be sown in late March, and the first buds subsequently developing should be retained. The cuttings of the plants in the second series should be inserted about

the third week in April, or a trifle earlier, and the last lot should be taken in hand during the closing days of April or the first few days in May. When once these cuttings become rooted the young plants must be handled carefully, and, when established, should be grown on with all possible vigour.

Potting Camellias (E. Jones).—Camellias are best repotted as soon as the bloom is off and new growth is pushing. They are rather impatient of root disturbance, and will do a long time in the same soil, if helped with a slight dressing of soot, or soot-water. They must be well drained, for, although enjoying abundance of water while growing, the least suspicion of stagnation is fatal to their thriving. Use a compost of fibrous or turfy loam, with a little peat. A dash of sharp sand, not too fine a compost, and firm potting are great aids. Camellias often fail through change of position and temperature. A cool and moist bottom, with plenty of overhead syringing and the avoidance of a sodden soil, are important.

Malmalson Carnations falling (G. E. T.).—A light, airy structure is very necessary for this class of Carnations, and failure to open is caused by a moist, stagnant atmosphere. The buds are so hard and massive that they often set in at this season before the flowers expand, even in structures that are built especially for their accommodation. The Malmalson section of Carnations is not naturally winter-flowering, being at their best, as a rule, in June and July, at which time the warm, summer weather assists the expansion of the blossoms. For this purpose they are layered as soon after flowering as possible, and shifted on when sufficiently strong to be wintered in their flowering pots (6 inches in diameter) in a greenhouse temperature, where there is a little fire-heat in order to keep up a circulation of air. If old plants are kept over they should, in September, be cleaned and repotted, taking away as much of the old soil as can be done without seriously disturbing the roots.

Rose Armosa (Woodhouse).—In its way there are few more beautiful autumnal Roses than this good old variety. Although grouped with the Bourbons, for all practical purposes it is a Bourbon or Monthly Rose. There is not quite the continuous blossoming we get in the old Bush Monthly, for during August the plants are almost devoid of bloom. They, however, make up for it later in the season, when every Rose is so much valued. With this Rose, as with many of the Teas, the continuity of blossoming may be assisted by cutting off the flowers with a fairly long stem as soon as the frills has developed. Some growers may even be cut back before they develop if the plant is bearing a profusion, as it should do. The colour of Armosa reminds one of the H. P. Mrs. Sherman Crawford. The form is very regular, and it is fairly double. Perhaps no Rose is more lovely when used for table decoration.

TREES AND SHRUBS.

Clipping Hollies (H. O. H.).—The best time for cutting Hollies is early in the spring, about the end of February, before they have begun to grow. Never clip them with a shears, but cut them in with a sharp knife.

Increasing Fernetyas (L. R.).—Fernetyas are easily increased by layering the roots in autumn, or by sowing the seeds in spring in sandy peat in cold-frames, or in gentle heat in pots, afterwards pricking out the seedlings carefully when well above the surface of the soil.

FRUIT.

Hedge of Gooseberries (E.).—It is not likely that you will be able to get bushes of a bearing size trained in the way you propose. There is, however, no difficulty in starting with young trees to bring them into the form you want, as any nurseryman would make a suitable selection for you. Early Sulphur will probably make the best cordou form, as the growth is stiff; but others will not be difficult if you commence training the branches while they are young.

Vines in pots (A.).—Seven-inch pots are not large enough for Vines to fruit in. If they are sown the pots should not be less than 12 inches across the top; the weaker canes would do in pots an inch less. When the canes are well ripened—say, towards the end of September—they should be stood out-of-doors at the foot of a south wall and freely supplied with water during hot and dry weather. The pots ought to be protected from frost during the winter with leaves or partly-decayed manure.

Pruning young Currant bushes (M. E. C. Moss).—Generally, with newly-planted things, bushes or otherwise, it is best to allow a few weeks to elapse from the planting until the pruning is done. That not only enables the soil to become settled and firm, but the roots to push down growth, and, in that way, become partially established in the soil. Then, when the pruning is done, and the end of February or early in March is soon enough, new growth soon follows, and root-let-down and wood growth are alike good. Your object in pruning these young bushes is to enable proper heads to be formed; hence, in cutting back the existing shoots to about one-third their present length you compel the lower buds to break into three times the number of shoots, thus laying the foundation of good bushes. Those may still following winter be cut back to one-half their length. Black Currants, later, need not be shortened—only just topped, and kept fairly thin. Old Red Currants, summer shoots, after a good bush is formed, should be quite hard cut back each year, as these bear fruit only on spurs on old wood.

VEGETABLES.

Moss-litter-manure (R. N. S.).—The value of Moss-litter is found in its capacity to absorb animal manure, which it does thoroughly, and it, after such use, it is put into a heap, turned two or three times to cause it to sweeten, but not to heat, then it answers fairly well for mulching, but it is not so valuable for digging into the ground as straw litter.

The use of Kainit (A. S. G.).—You ask "In what proportion Kainit should be mixed with (1) ordinary garden soil; (2) with manure in order to sterilise." We confess our inability to understand your meaning, and we shall be glad if you will explain. Kainit is a potassic manure of much use in various soils and for particular crops, and the proportion in which it should be used will depend on the soil and on the crop for which it is applied. But what is the object in sterilising may be well to con-

Parsley unsatisfactory (A.).—Parsley suffers from drought in poor soil, and a check sometimes leads to canker or insect attacks. Wood-ashes has a good effect in keeping Parsley free from canker at the collar, and watering with soap-suds tends to prevent attacks from insects. It is too late to sow again now, but it is possible if some of the roots were taken up, dipped in strong liquid-manure, and planted in a frame, they would start away in the fresh soil and make a lot of useful growth. If the plants are cleared where they stand of all discoloured leaves, and well soaked with soot-water, a beneficial change will be effected.

Decayed Parsnips (W. D.).—The brown spots seen on your Parsnips are the products of a fungus, usually generated in the soil by too much wet, or too rich dressings of manure. It is well not to have Parsnip soil too highly manured, as large roots not only are likely to be thus affected, but they are relatively softer and more watery than are roots rather smaller, and grown somewhat closer together. To have Parsnips good when cooked they should never be too large to boil whole, and should be merely scraped and not peeled, or cut through the centre. If your roots are still in the ground give them a thorough dense dusting with fresh slacked lime. Also another autumn give a couple of such lime dressings a month apart, hoeing in the lime between the roots. That helps to destroy the fungus and sweeten the soil.

SHORT REPLIES.

Wood Anemone.—No, Clematis indivisa is a greenhouse plant and will not do in the open air. Winterhill.—See note on "Tree-leaves" in issue of December 13th, p. 538. Ater.—Yes, cut it down and will start from the root-stock in the spring. M. H. McWilliam.—Impossible to name from specimen sent, which had fallen to pieces. Kuoiv.—Do not understand your query. Kerry.—It is very probable that the Chrysanthemums were named differently, but, unfortunately, they seem to have been all the same sort. Had you verified the colours the previous season? Does on their own roots will not behave as you say. Those grafted may do so, the stock taking the place of the graft in many cases if the suckers are not pulled off. D. S. T.—You will find an article dealing with "Raising Ferns from seed" in the issue of Dec. 13th, 1901, which can be had of the publisher, price 13d. We doubt if you can buy Fern spores in A. E. Bennett's. Yes, we believe so, but only in the case of some persons. Manzmann.—1, See reply to "L. Lambly," re "Treatment of Oleander," in our issue of Dec. 13th, p. 514. 2, Yes, plane off the surface and rub over with white-lead paint. 3, Put in the cuttings of your Chrysanthemums at once. These you will find springing up from the old stool. When you have got sufficient stock throw the old plants away. See article "Preparing for next season," in our issue of Dec. 6th, p. 538. Thomas.—The only thing you can do is to grub them up. If not, they will all spring from the bottom again. J. W. W.—See article on "The Mistletoe," with illustration, in our issue of Jan. 5th, 1901, which can be had of the publisher, price 13d. Pencil.—A warning, not in gardening, question. We have handed your query to the author of *Frame and House*. Nottingham.—We shall be glad if you will kindly give us the original query, and we will try and help you. Toby.—You ought to put on a good dressing of rotten manure, and allow the winter rains to wash the goodness from this into the soil. Weak liquid-manure in the spring, when the plants are to full growth, will do good. Standard.—See reply to "Worcestershire," re "Twenty good standard Roses," on this page.

NAMES OF PLANTS AND FRUITS.

Names of plants.—Miss F. L. Clark.—The Hoop-in-Hose Polyanthus.—Oxfordshire.—1, Phacelidium aureum; 2, Adiantum concinnum latum; 3, Petal serrulata cristata; 4, Libonia floribunda. Thanks for such fine specimens.

Names of fruits.—Geo. Goldard.—Apple Kentish Filibasket.—J. H. Marshall.—Probably Allerton.

Book received.—Official Catalogue of the National Rose Society. Fifth and revised edition.

Catalogues received.—Dicksons, Chester.—Catalogue of General Nursery Stock.—Hange and Schmidt, Erfurt.—Trade and Retail Catalogue for 1902.—Ernst Benary, Erfurt.—General Trade Catalogue of Seeds for 1902.—S. F. Richmond, Osest, Yorks.—Pisicripic Catalogue of Chrysanthemums.—Viliorin, Andreux et Cie, 4, Quaidala Bergeserie, Paris.—Catalogue of Seeds.

United Horticultural Benefit and Provident Society.—The monthly committee meeting of this society was held at the Calsonian Hotel, Adelphi-terrace, Strand, on Monday evening last. Mr. C. H. Curtis presided. Twelve members were reported on the sick fund. Seven new members were elected. Two members were granted £1 10s. each from the convalescent fund. A cheque for £79 18s. was granted to a lapsed member, being the amount standing to his credit in the ledger.

A FAMILIAR NAME

awakens old memories. Do you remember the children's party of thirty years ago when the jelly wouldn't "Jell," as cook said in an awestruck whisper to her mistress. We never think of Table Jellies without remembering that tragic event. Such a thing could not have happened if Chivers' Jellies had been, but they were not to be had then. There is that to our advantage now. These Jellies are absolutely pure and reliable, and are flavoured with ripe Fruit Juices. Sold at the Grosvenor in pint and quart packets. For the children's parties you should have Cambridge Lemnada. "It beats all." Chivers and Sons, Limited, 11, Abchurch Lane, Cambridge. First English Fruit Factory, Ltd., Factory.

HARTLEY & SUGDEN, Ltd., HALIFAX

WROUGHT IRON BOILERS

FOR HEATING GREENHOUSES, CONSERVATORIES.

CATALOGUE on application.

HALIFAX BOILER.

THE LOUGHBOROUGH BOILER.

20,000 IN USE.

The Pioneer of Cheap, Simple, and Effective Heating for Small Greenhouse.

The immense sale of this Boiler, and the numerous imitations of it sent out in recent years, afford abundant testimony of its undoubted success.

No. 1, to heat 100 feet of 2-inch pipe	£2 17 0
No. 2, " 200 " " "	3 12 0
No. 3, " 400 " " "	5 10 0

Also in larger sizes, heating up to 1,000 ft. of 2-inch pipe. Complete apparatus for £4 16s. 6d. Illustrated Lists and Estimates on application.

Patent Greenhouse BOILERS.

The special merits of our Boilers are—

- 1.—Long Burning.
- 2.—Even Temperature.
- 3.—No Trouble.
- 4.—The Feeders being hinged can be pulled forward when desired, completely exposing fire-box.

In these particulars our Boilers are beyond competition.

Guaranteed Minimum Burning 12 Hours Without Attention.

It goes without saying that the large reserve of fuel in the Feeder insures burning for at least four times longer than is possible with ordinary boilers. Unusually factory Boilers can be replaced in a few hours' work without moving existing pipes.

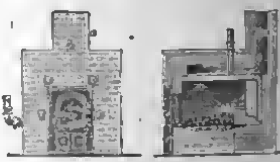

EXTRACTS FROM LETTERS RECEIVED:—

"My gardener says he never had such a stove before, so easy to work, and does its work so well." "Does its work splendidly, and is certainly the least trouble of any stove I ever had." "My maids manage it." "The last No. 2 I had from you always goes 24 hours at a stretch." "I never look at it but once a day, and have a good even heat the whole 24 hours."

For prices, particulars, and Estimates for Complete Apparatus, apply

CHARMING XMAS GIFTS. CAMPBELL'S GENUINE COLUMBIA GRAPHOPHONES

and COLUMBIA RECORDS are the best. Gained the Grand Prix, Paris Exhibition, 1900. A Fascinating & Unrivalled Entertainer for the Home Circle.

YOU CAN MAKE YOUR OWN RECORDS

CAMPBELL'S Columbia GRAPHOPHONE is the best Talking & Singing machine in the market.

Special Xmas Price to readers of GARDENING, £2 15s. Carriage Paid, with 3 Records free. Sold only by Campbell and Co., Musical Instrument Makers, 116, Trongate, Glasgow. *1 Month, over 50 Years.*

The following are Campbell's leading cheap good lines in (Gardening) **TALKING MACHINES. (COUPON.**

The "Lyra" Graphophone, with 2 Records	15 0
The "Gom" do. with Recorder & 2 Records	1 5 0
The "Favourite" do. do. do.	2 2 0

The above sent carriage paid in Great Britain.

Beware of the German-made rubbish so extensively advertised by nondescript dealers. We are Musical Instrument Makers & Talking Machine Experts, and understand all about the goods we sell. 10,000 London-made Records to select from at 1s. each. Send for our New Price List for 1903 of all kinds of Musical Instruments and Talking Machines. Sold only by

CAMPBELL & CO., 116, TRONGATE, GLASGOW.

CHAS. P. KINNELL & CO., LTD., SILVER MEDAL HORSE-SHOE BOILER

(KINNELL'S PATENT).

SECTION OF BOILER, SHOWING ACTION OF HOT BLAST.

Patents 10 398 & 10 674.

AWARDED 3 FIRST PRIZES IN OPEN COMPETITION. Guaranteed 12 HOURS Without to Burn Attention.

SEND FOR LIST WITH FULL INFORMATION, POST FREE. Offices, Warehouse, and Works: **SOUTHWARK ST., LONDON, S.E.**

THE IVANHOE IS THE BEST

for Small Greenhouses.

WILL HEAT UP TO 80° OF 4in. PIPE.

SUPERIOR FINISH! GREAT EFFICIENCY! MODERATE PRICE!

BOILER only, from £3 3s.

Send for LIST and name of Local Agent.

R. JENKINS & CO., ROTHERHAM

16-

FOR ROOKS, PIGEONS, RABBITS.

Single barrel, hammerless, breech-loading Shot Gun, converted from Government Rifle, and fitted to take 12-gauge OF shot cartridges; specially bored by an improved process for long range and great penetration. Unquestioned best for long distance shooting, 15s. each. Double-barrelled breech-loaders from 35s. Air Guns, 12s. 6d. Wadding-clip Gun, 12s. 6d. Alarm Gun, 7s. 6d. Send 3 stamps for Price List.

MIDLAND GUN CO., Bath-street, Birmingham.

A BARGAIN, 9s. 6d.— Powerful 4-gauge BINOCULAR; 9 lenses, 30-mile range, silvered-on-glass shades, leather sling case and straps. **12/6**, extra powerful.

DOUBLE ALBERT (cut), excellent, 12s. 6d. (Patent) sent for inspection before payment.—**MCCARTHY, Pawnbroker, 44, Archway-road, London, N.**

A BARGAIN, 10s. 6d.— Gent's magnificent 18-carat gold-cased KEYLESS BUNTING; compact, jewelled lever balance, perfect timekeeper, 10 years warranty. Also Gent's fashionable 18-carat rolled gold watch.

BLUCHERS.—5,000 pairs sewn down Bluchers, quite new; splendid leather color. Will suit one pair, any size, post free, 3s. 6d. Cash returned if not approved of.—**H. J. GASSON, Government Contractor, Rye.**

TARPAULIN.—I have a great quantity of large pieces of Tarpaulin, some new, but all of the best Navy canvas, purchased from Government, useful for covers for carts, waggons, and machinery, at 25s. per cwt.; 100 suitable for covers for buildings, at 12s. per cwt. Cash returned if not approved of.—**H. J. GASSON, Government Contractor, Rye.**

PLANTS AND FLOWERS.

CHRYSANTHEMUMS.

CHRYSANTHEMUMS FOR COLD GREENHOUSE.

I would be much obliged if you would give me a selection of Japanese Chrysanthemums suitable for flowering in a cold greenhouse? I do not want to grow exhibition flowers, but bush plants with fifteen to twenty fair-sized blooms. I want good, decided colours, not washy tints. Will I be able to grow sorts like Mrs. Coombes, Mr. L. Kemp, Phœbus, Miss A. Byron, and others, or do the big exhibition sorts lend themselves to such treatment? When ought I to buy the cuttings? I have room for thirty or forty plants, but I think fifteen sorts would be enough. I have Vivand Morel, Lady Rowland, Charles Davis, President Nolin, Lady Ridgway, Source d'Or, Mme. H. Bentz, Mrs. S. C. Troby, and Mme. de Sevin, but they were not a success. I planted them out and potted them when the flowers showed colour. They were all pinched end of June, and some before that. Some have quite small buds still. Any of above you think worth growing next year, please include in your selection. They will be grown in pots next year.—*DECONATIVE, Ireland.*

[Gmowers are at last beginning to see that the real value of the flowers is determined more by the freedom of flowering of the plants than in the development of one or two exhibition blooms which, for decoration, have little to commend them. The sorts which we describe have been grown in this way, and have points of merit, in so far as regards colour and form, over many others. There is nothing like commencing in good time. To make big plants, early propagation is important. Therefore, procure cuttings as soon as possible and insert these singly into thumb-pots, using good fibrous loam and leaf-mould in equal parts, adding thereto, very freely, coarse silver-sand or clean road grit. Pinch out the points of young plants towards the latter part of March and take up three or four of the strongest shoots. During June they should each break naturally, and at this time two new shoots should be retained on each of those which were taken up subsequent to the pinching in March. From this point let the plants grow on to the terminal-buds, selecting three shoots and a bud on each one. These terminal-buds always develop blooms of beautiful colour and good form; the blooms also keep fresh for a long time, and rarely, if ever, are known to thump. The following varieties may be obtained cheaply:—

Mrs. ALICE BYRON is a pure white flower. The plant, which attains a height of about 5 feet, has a good constitution.

Mons. CH. MOLIN is of a rich yellowish-orange colour, and on terminal buds very brilliant. The plant is of easy culture, and in height slightly over 5 feet.

Mrs. C. BOWEN—This is a well-known late white Japanese kind, and one of the best for late work. Waxy-white aptly describes the colour, and the height of the plant is from 4 feet to 5 feet.

Mrs. COOMBS—One of the easiest plants to grow, developing pretty, rosy flesh-pink blooms of a pleasing kind. Height about 7 feet.

Mrs. GEORGE MILEHAM—An introduction of last spring, and a decided acquisition. Colour pleasing rose-pink, with silvery-reverse. Height about 5 feet.

Mrs. GREENFIELD—Introduced two seasons since, and an advance upon Phœbus. The colour is a deep rich shade of yellow, and the form is distinctly pretty. Good constitution. Height between 4 feet and 5 feet.

N.C.S. JEMMER—This is a Japanese introduced, and the colour is a dainty shade of silvery-mauve. The plant is of easy culture, and grows rather more than 5 feet high.

SULEH D'OCOTBRE—For late October and early November displays this canary-yellow flower should stand you in good stead. It is of easy culture, possesses a good constitution, and seldom exceeds 5 feet in height.

Bronze SULEH D'OCOTBRE—This is a lovely soft shade of bronze, and is the same in every respect but colour as the parent variety described above.

CHRIMIS SOURCE D'OR—This variety is to be preferred to the parent owing to the glorious colour of the sport. The colour may be described as rich crimson terra-cotta, paling somewhat with age. Habit good. Height about 4 feet.

LIZZIE ADLER—This is a rich yellow sport from Source d'Or, and a decided acquisition to the decorative section of these plants. Habit, constitution, and height identical with those of the last-named.

WESTERN KING—This develops lovely white blooms of good form. Good habit, free, and robust. Rather late. Height 5 feet.

VIVAND MOREL—No collection would be complete without this easily-grown plant. Grow on carefully from free-growing cuttings the plants of this variety and its sports do well. Colour silvery mauve-pink. Height rather more than 5 feet.

CHARLES DAVIS—This is a rosy-bronze sport from the last named, and requires exactly similar treatment. Height also identical.

LADY HANHAM—This variety will develop blooms of a charming golden rosy-corse, although the colour sometimes is cerise on a buff ground. This completes a charming trio, known generally as the Vivand Morel family of plants.

CHARLES LONGLEY—For its colour, which is a rich rosy-purple, this plant should be grown. It is rather tall, however, attaining a height of about 6 feet.

COMTE F. LORANI—Although this beautiful Japanese kind has been in commerce for some time, it has lost none of its charms. The colour is a very pretty rosy-pink, and the drooping form of the blooms is also most dainty. Height between 3 feet and 4 feet.

WILLIAM SEWARD—A deep rich crimson, once very popular for exhibition, but being too small for that purpose now is rarely met with. This is of easy culture, and on terminal buds is slightly above 5 feet in height.

JOHN SHIMMERON—This is a bright rich crimson Japanese, succeeding remarkably well when grown freely. Very dwarf and sturdy, seldom exceeding 4 feet in height.

YELLOW LA TRIOMPHANTE—A rich yellow and free-flowering. It is a sport from the old La Triomphante, which is still largely grown for market. Height rather less than 5 feet.

with flat and rather broad petals. Colour chestnut-bronze, with bronze reverse. Good branching habit. Height about 5 feet or rather less.

LOUISE—A pretty incurved bloom of Japanese form, and when grown freely a valuable decorative plant. Colour flesh-pink. Height about 4 feet on terminal buds.

LADY SALISBURY—The blooms of this are pretty when the plant is grown in bush form, their colour being deep yellow, freely suffused crimson. Height about 5 feet.

MISS W.M. HOMER—A plant of the easiest culture, and useful for late October displays. Colour rich crimson, tipped gold. Height about 4 feet.—*E. G.]*

CHRYSANTHEMUMS—SOME OF THE BEST EXHIBITION JAPANESE NOVELTIES.

Most of the undermentioned Japanese varieties have either received an award of merit from the Royal Horticultural Society, or a first-class certificate of the National Chrysanthemum Society. In some cases a commendation has been made in their favour. In a few instances the blooms from an exhibition standpoint are so unimpressive, that, had they been exhibited when at their best, there is little doubt they would have been recognised with an award of some sort.

GEORGE MILEHAM—This is a very large and handsome Japanese bloom, with long reflexed florets of medium width, making a spreading flower and slightly drooping. The colour is a rich glowing char-crimson with pale bronze reverse, the latter showing on the ends of the lower petals. F.C.C., N.C.S.

HENRY PERKINS—This bloom has been shown in all conditions. From an early bud selection the colour is reddish-crimson on a deep yellow ground, while that from a late second crown bud selection is a rich crimson self. The petals are very long and broad, and build up a bloom of great depth, some 8 inches, and proportionate breadth. The reverse is a golden bronze colour. This variety has been certificated in the provinces.

MISS MILDERED WARE—An English-raised seedling of great promise, certificated by the N.C.S. 27th October last. This is a seedling from Mme. Carnot, and resembles in form that superb sort. The blooms have been aptly described as a Lady Hanham-coloured Mme. Carnot, and as such should be appreciated by exhibitors. The florets are of medium size, and have a golden reverse. Grown either in the orthodox manner, or in 6-inch or 7-inch pots, the plant is a great success, coming good on all buds.

THE HON. Mrs. A. AGLAND—This is a lovely rich yellow Japanese bloom, in colour midway between Edith Tabor and the rich butter-yellow R. Hooper Pearson. The florets are fairly broad and long, incurving at the tips and building up a reflexing bloom of even form and good quality. A.M., R.H.S.

MISS OLIVE MILLER—An English-raised seedling of Japanese origin, large, full, and deep, of pleasing form, having long and fairly broad

florets and grooved, incurving and curling at the tips. The colour may be described as a distinct shade of pale rosy-pink on a silvery-white ground, and with a silvery-white reverse. When finished the blooms are quite 9 inches deep, and correspondingly broad. The plant is of easy culture, and will develop at least five handsome blooms on each plant. F.C.C., N.C.S.

F. S. VALLIS.—A large and refined Japanese bloom. This variety is of continental origin, and bids fair to take a leading position. The colour is a deep canary yellow, and the flower, which is of deep build, is of open form and drooping. Some growers say it is too near G. J. Warreu. Certificated at the Sheffield Show, November 14th last.

MISS NELLIE FULTON.—This is a splendid type of Japanese incurved, having broad petals of great length, building up a beautiful bloom of lovely form. It may be regarded as an advance upon Miss Alice Byron, which it somewhat resembles. Colour pleasing shade of creamy white. A.M., R.H.S.

MME. PAOLA RABANELLI.—This is a continental introduction of superb quality. The petals are broad and very long, slightly twisting and curling, and developing a bloom of high quality and of elegant form; colour soft pearly-pink on a cream ground with a yellowish centre. F.C.C., N.C.S.; A.M., R.H.S.

GEORGE PENFORD.—Another of the Japanese flowers of the season. A very large, heavy-looking bloom, with long and broad strap-like petals of splendid substance curling prettily at the tips, and sometimes showing the rich golden reverse. Colour deep rich crimson. F.C.C., N.C.S.

EDITH SMITH.—A very chaste, glossy, creamy-white Japanese of open form, having long, curly broad petals slightly twisted and curled, and forming a graceful and drooping bloom of good quality. Certificated at Sheffield Show.

MR. T. W. POCKETT.—In Mr. R. C. Pulling's group at the Royal Aquarium Show, on November 14th last, a vase was filled with this handsome Japanese flower. It is a very full bloom of even, drooping form and deep build, with petals of medium breadth; colour deep canary yellow. The plant has a good habit. This variety, I believe, received an award of merit last season.

DUKE OF DEVONSHIRE.—A large Japanese bloom of graceful and elegant build, having long, curling, and twisting florets, and making a charming exhibition flower. Colour yellow in the centre, paling at the edges and tinted rosy-red. The N.C.S. Committee desired to see this variety again. W. V.

How to fix a sport.—No doubt many good Chrysanthemum sports are lost because of the lack of knowledge respecting the treatment necessary to fix them. This fixing of sports is not by any means difficult, and should be carried out in the following manner: Should the plant be growing in a pot, the plant should be shaken out, and the soil slightly loosed. It should then be denuded of all shoots, except the branch on which the sport has developed. Until the bloom is spent it should be permitted to remain, but after this it is better to remove it. Retain the whole of the shoot on which the sport was produced, taking care also to retain the leaves intact. As the plant lies on its side, cover the roots, stem, and shoots with any light and gritty compost. Cocoa-nut-fibre refuse, kept just moist, answers equally well and is less disagreeable to handle than the ordinary light compost. If the plant can be plunged where a gentle bottom heat can be maintained, so much the better. The axils of the leaves, but not the leaves themselves, should be covered with the fibre, as this induces new shoots to break away at their base. Under ordinary conditions the new shoots will not be long before they make their appearance. When they have attained a length of about 2½ inches detach them, with a sharp knife, at one joint removed from the main stem. Trim off the cuttings just below a joint, and insert them in some light and gritty compost, either singly in thin pots, or else a number around

the edge of a 3-inch pot. When propagated and rooted grow on with all vigour. The succeeding season should see each of the propagated pieces bearing bloom, similar to the sport.—W. V. T.

ORCHIDS.

CYPRIPEDIUM INSIGNE HAREFIELD HALL VARIETY.

THE first public record of the existence of *Cypripedium insigne* Harefield Hall variety, so far as we can gather, was that the plant was first exhibited at the Royal Horticultural Society's meeting at the Drill Hall, on December 16th, 1897, as *C. insigne* giganteum. It was exhibited by Mr. E. Ashworth, of Harefield Hall, Cheshire. A second plant was also exhibited by the late Major Mason, from his collection at "The Firs," Warwick, which, when placed before the Orchid committee, scored at

plant being in a 5-inch pot: The dorsal sepal is 2½ inches across and about the same in length, but reflexing at the top causes it to appear shorter. The upper portion and outer margins have a broad band of white, the central area green suffused with yellow, the large blotchings on the central area deep brown, those on the white, purple, as in *C. punctatum-violaceum*. The petals are each an inch broad, greenish-yellow, heavily suffused with polished brown, the lower sepal green, suffused with yellow and spotted with brown and purple.

Like most other varieties of *C. insigne*, the conditions under which the plants are grown had considerable effect on the substance and quality of the blossoms. Many recommend that *C. insigne* and its forms should be grown in a cold-house. I do not advocate their culture in the stove, but I find they do best when they can be accommodated in a house where the normal winter conditions are maintained:

Cypripedium insigne Harefield Hall variety. From a photograph taken in Messrs. Low's nursery at Bush Hill Park, Enfield.

that time be identical. Mr. Ashworth, having considerably improved his plant, exhibited it again on December 13th, 1898, when the coveted first-class certificate was awarded to the plant, under the name of *C. insigne* "Harefield Hall variety." It is the largest of its race, and it is a pity, therefore, that the original name was not adhered to, for none more appropriate could be found. Some have given it as their opinion that this variety lacks the refinement of most other kinds among the numerous desirable varieties of *C. insigne* that have become so prominent in Orchid collections during the last few years. Let this be as it may, that like *C. insigne* Sanloro among the yellows, *C. i.* "Harefield Hall variety" holds its own among the coloured kinds cannot be denied, and notwithstanding the fact that wholesale division has been made, the plant has retained its natural vigour, and it blooms far more freely than the older kinds, flowering as the latter are found to be. To show the proportions of the flower, the following particulars are taken from a bloom before me: The

axils degs., rising to 60 degs. Where such conditions are maintained the plants are not nearly so difficult to manage; the watering may be done with far less restriction than is required with a lower degree of temperature. I have found also that the varieties of *C. insigne* are gross feeders and require repotting annually while in a small state, when grown to a large size less frequent potting will be necessary. The potting compost used must be governed by the conditions under which the plants have to be cultivated. In the neighbourhood of London and other smoky districts the compost must be of a porous nature, so that an over-abundant supply of moisture is not retained about the roots of the plants during dull or foggy weather. Peat, Sphagnum Moss, and a little leaf-soil intermixed with plenty of rough sand I have found the best material to use in unfavourable districts such as mentioned above. In more favourable surroundings, fibrous loam in liberal proportion may be added to the above compost with

advantage. The material should be pressed moderately firm about the roots of the plant, keeping the rhizome a little below the rim of the pot and mounding the compost slightly towards the centre. The pots used should be clean and filled to one-third their depth with clean broken crocks. As soon as potting is completed, thoroughly water the plants with rain water, using a moderately coarse rose on the can. The compost should be kept moist, but not wet, until the plant becomes thoroughly rooted, then more liberal watering may be afforded. The best season in which to repot the varieties of *C. insignis* as early as possible after they have flowered in the New Year. Root action generally commences as soon as the flowering period is over, and the plants are thus enabled to become established without any apparent distress. H. J. C.

Young growths on stems of Dendrobium nobile.—Would you kindly tell me what is the reason of and the cure for Dendrobium (nobile especially) putting out new small growths along the main new stems?—A. R. M.

[There are various causes which induce young growths to appear along the stems or pseudobulbs of Dendrobiums. Like many others who send us queries, you omit to mention under what conditions your plants are cultivated. We cannot, therefore, without knowledge of the system of culture, be of much assistance to you, and can only reply to you in an unsatisfactory, or at any rate an indefinite manner. We append the following causes, hoping that you may be able to ascertain where your treatment has been amiss. One of the principal causes will be found in treating the plants too kindly—that is, affording too much heat and moisture at a season when the plants should be resting. This brings about unripened wood and premature growth. A second cause is brought about by bringing plants that have been thoroughly ripened, and because they show slight indications of the flower buds from the cool conditions in which they have been resting, directly into the hot, humid conditions of the stove. The result is that the buds become too vigorous from the sudden change, and the intended flower buds are under too liberal treatment developed into growth. Another cause will be found in not taking care in applying moisture gradually when the plants are removed from their resting quarters into the warm house. The plants require little more moisture than the humid conditions of the atmosphere to sustain them in their normal conditions at the present season. If the pseudobulbs are found to be shrinking, a slight dip in tepid water soon revives them. It is never safe to water Dendrobiums flowering early in the year until the buds are sufficiently unfolded, so that the flower buds can be distinctly distinguished. After that time more liberal treatment may be afforded. It appears to us that your Dendrobiums have been too liberally treated, or they would not have their flowers sufficiently advanced to cause you anxiety at this early season. February and March are the better season.—H. J. C.]

ROSES.

GARDEN ARBOURS.

SUMMER HOUSES, gazebos, arbours, and such-like resting places, are amongst the most valuable of garden structures, since they provide retreats where shelter from the burning rays of the midsummer sun is afforded while permitting views of the lawns, flower borders, and surrounding features of the garden to be obtained by their occupants. The general effect of a garden can often be better studied by sitting quietly in an arbour than by a tour of the grounds where every fresh stand-point reveals a new prospect. Although the primary object of summer-houses is the very necessary one of affording shade in the summer, they are also useful as shelters from rain, and it is questionable if there is any sensation connected with the garden more delightful than that experienced by anyone under cover in the open air when, after long weeks of drought, the first heavy thunder-shower falls upon the parched earth. The lambent flame of sheet-lightning gleams momentarily amid the purple-black clouds, the distant mutterings of thunder—those "voices calling out of the blue"—

roll afar. The great drops fall perpendicularly in the windless air, and every leaf is vocal in the glad rain-song, while fragrances that have long slumbered in leaf and blossom awake and fill the still atmosphere with perfume. The Sweet Brier's incense steals through the dripping foliage, the damp earth exhales a grateful odour, and on the lawns "the soft rain that heals the mown, the many-wounded Grass, soothing it with the sweetness of all music, the hush that lives between music and silence," descending like a benediction, draws forth halmy scents from every freshened blade.

Arbours should be simply constructed, all needless ornamentation is to be deprecated, though where strong-growing climbers are allowed to ramble at will over the structure, imperfections of design are speedily hidden, and even an erection of corrugated iron, the most offensive material that can be imagined for garden work, has its cheap ugliness soon shrouded from view by the gracious mantle of clambering plants. Of flowering subjects for covering arbours, climbing Roses, Jasmine, Clematises of sorts, Menispermum canadense, Wistaria, Tecoma radicans, in the warmer districts, Solanum jasminoides and Physianuto albens, with the fragrant blossomed Stauntonia latifolia may be mentioned, while of climbers

up the Roses, thoroughly turns the bed over, adds fresh soil, and replants them the following day. This, of course, causes the leaves to wither, they look unhappy, and we get no late Roses. He heavily manures them in winter, prunes in spring, and waters fairly copiously with the hose in summer. Last autumn he did not lift the Roses, and last summer we had fewer Roses than ever. He has lifted them again this autumn. The soil of the garden is good, with a gravelly clay subsoil. The climate is not dry, rainfall a high average. The main characteristic is much grey sunless weather without actual rain, but a moist atmosphere. Our main enemy is strong wind. Can you tell me if this method would be advisable under any circumstances, and if so, when? Other people, whose Roses are not lifted over, seem to get quantities of bloom there.

[As you well remark, the treatment of the Roses is both unnatural and peculiar. We recommend transplanting at intervals of three or four years where the plants appear to require it, but when they grow freely we always advise our readers to let well alone. Some of our best bush plants of the Hybrid Perpetual tribe have not been transplanted since they were planted some twenty years ago. It is true we have a good deep soil and the borders were well prepared, and also receive an annual top-dressing of farmyard-manure, which benefits them considerably. It appears to us that the fault regarding the plants you mention is either in the method of pruning adopted, or in the unsuitability of the varieties,

A Rose covered arbour. From a photograph by Mr. Jas. F. Tyler, Halstead, Essex.

whose attractiveness is due to their foliage there are the Vines, of which *V. Cœnigeticæ* and *V. vitifera purpurea*, the Claret Vine, are valuable on account of their autumnal colouring, as are the Virginian Creepers, now also classed among the Vines, and although these have the demerit of being bare of leaves in the winter, this is scarcely an objection in the case of a summer-house which is untenanted in the cold weather. *Aristolochia Siphia*, the Dutchman's Pipe, is a handsome climber with enormous leaves, and the Ivies will form a perennial covering of glossy green.

S. W. F.

NOTES AND REPLIES.

Six fragrant Roses for trellis.—I shall be obliged if you will give me the names of six scented climbing Roses for training on a trellis work facing south? I want, if possible, six different colours, and to be free-blooming.—CLOTHES-DARK.

[Blairst, No. 2, Gloire de Dijon, Pink Rover, Waldman Number No. 3, Mme. Isaac Perrier, Mme. Alfred Carrière, are all good, and would grow and flower freely.]

Roses not blooming in autumn.—My father's gardener fails to produce what I consider a sufficient quantity of flower on his Hybrid Perpetual Roses. I think his method of treating them unnatural and peculiar, and would like to have your opinion. His method is as follows: He makes a bed of clay about 2 feet 6 inches below the surface, puts very good soil on top, and plants the Roses in it. In one of the beds he gave up the clay formation last year, as some of the roots rotted off. He thinks, about the beginning of November, he

or perhaps both. There are many Hybrid Perpetuals that flower very sparsely in autumn, but others, such as Mrs. John Laing, Marquise de Castellane, Alfred K. Williams, Ella Gordon, Victor Verlier, Victor Hugo, Charles Lefebvre, etc., give us at that season, and also in summer, a rich display of beautiful flowers. The correct method in pruning this tribe is to cut clean away the old wood—that is, growths three years old and more—but the one and two-year-old shoots are retained a good length, say 12 inches to 15 inches for the vigorous kinds, and the more moderate, such as Baroness Rothschild, may be cut down close to the ground, if you like, and they flower freely. The tribe certainly is partial to a clayey soil, but we do not consider the method adopted of putting a bed of clay beneath the better soil at all a good one, as it must tend to hinder the free outlet of superfluous water, the retention of which has doubtless caused the rotted roots. It would be much better if an inch or two of clay were spread on the surface each season before frost comes, and in spring, when it has become disintegrated by frost, forked in lightly with the manure. Then, again, as your district gets rather a heavy rainfall, we should advise a more regular application of water in summer. One really good soaking, if the weather be very dry, would probably suffice, the most impor-

tant item of cultivation being frequent stirring of the surface-soil, which would prevent undue evaporation of moisture. As you are anxious to obtain autumn bloom you should most certainly plant some of the freest-growing and hardiest of the Teas, such as Caroline Testout, Grace Darling, Clara Watson, Mme. Wagram, Augustine Guinoissean, Viscountess Folkestone, etc.]

ROOM AND WINDOW.

POINSETTIA PULCHERRIMA.

From November to the end of January flowers are scarce and valued accordingly. However, during this dull time the Poinsettia is to be had in perfection. The gorgeously-coloured "bracts" of the most intense scarlet are attractive above everything during the shortest days, and even a few of them are capable of brightening up stove, conservatory, or rooms in the most pleasing manner. Everyone who has a hot-bed, frame, and greenhouse should try to grow some of these. The flowers, as a rule, are over by the end of January, and from that time until the beginning of May the plants will remain dormant under the plant stage of a warm house. They will not need any water or other attention at all at this time. About the beginning of May they

bright sunshine for a few days; afterwards they will bear all the light possible. From the last potting until the middle of September they do remarkably well in a cool frame, and they should never be grown in a strong heat at any time in summer, as this causes them to make long, straggling growths, which are neither ornamental nor useful. Dwarf, sturdy shoots always produce the finest heads, and short plants are always more valuable than long ones. Another way of securing serviceable plants is to cut the old stems down to about a foot from the bottom, and allow all the side shoots which sprout out to grow. In this way some of them may have six, eight, ten, or twelve shoots, and as each of these will produce a showy head, very attractive plants are the result. When they are treated in this way it is best to repot the old plants as soon as the young shoots are a few inches long, and they may be potted again when growth is more advanced. As a rule, these branching specimen flower well in 8-inch and 10-inch pots, and apart from allowing the shoots to remain on instead of taking them as cuttings, and the putting them into pots, these plants are subject to just the same treatment as those raised from cuttings. In the autumn they are taken into a warmer and drier atmosphere, and here they soon develop their brilliant heads. Throughout all

three and in single flowers had been worked in as rosettes; similar rosettes were then stuck on at the corners. This tendency to overcrowding is generally rampant at flower shows. Again and again have I seen the most chaste decorations absolutely spoiled because decorators did not know when to stop. Not only is

TOO MUCH MATERIAL USED, but the material is too much mixed. Nothing tends to produce monotony so effectually as the employment of all kinds of plants and flowers at once. It is hardly too much to say that each decoration should consist of one or a few plants only. Not that only one flower may be used, though that often produces the most satisfactory results, but the flowers, foliage, and plants employed in any given decoration should harmonise. Many flowers, however, are strong enough to stand alone, such, for example, as Roses, Camellias, Lilacs, Valley Lilies, Lilies, Cyclamens, Lapagerias, Stephanotis, Passion-flowers, Gardenias, and hosts of other plants. With abundance of their own foliage and a few Ferns or Palms for extra greenery the most exquisite table decorations may be formed. With abundance of verdure it is astonishing how effective even white flowers may appear on a dinner table, especially as they may readily be fringed with bright Coleus, Iresine, Alternanthera, or other leaves. What better table decoration for Christmas than

Poinsettias in vases.

are brought out from beneath the stages, watered thoroughly, and then placed in a frame or house where the temperature is about 65 degs. Here they will speedily begin to grow, and emit young shoots all up the stems. When these are about 2 inches in length they are taken off as cuttings; each one is detached with a "heel"—i.e., a very little piece of the old wood attached—and they should then be inserted into the smallest-sized 2½-inch pots, filled with a half-and-half mixture of leaf-soil and sand. They are then plugged up to the rim of the pot in Cocoa-fibre in a hot-bed or Cucumber-house, where the bottom-heat is about 70 degs. Here they are not allowed to suffer from want of water, although they do not require much of this until the roots are formed, and they are also shaded from bright sunshine. Roots are soon made, and they are then withdrawn from the bottom-heat and placed on a shelf in the pit, and in a week or so after this shifted into larger-sized pots. From 2½-inch pots they are generally put into 3-inch ones, and from the latter into 6-inch or 7-inch ones, and in this size they are allowed to bloom the first year. In

POTTING, use a rough mixture of turfy loam, sand, and leaf-soil. Proper drainage is of the utmost importance, and firm potting aids to success in culture. Poinsettias lose much sap when injured, and this, having a weakening tendency, must be avoided as much as possible. After potting, keep close and shaded from

the period of their growth the greatest attention should be given to watering Poinsettias at the roots, as allowing them to become dry in any way causes the leaves to fall prematurely, and then the heads are poor.

TABLE DECORATION FOR CHRISTMAS.

HAVING long been an advocate for simplicity and lightness in table decoration, I would venture to offer a few remarks on the subject. There seems a natural tendency to run to excess in this matter. Many think that the greater the quantity of beautiful plants, flowers, or leaves on a table, the better the decoration. There can hardly be a greater mistake. As an illustration, I once saw a decoration in progress. Three light glasses occupied the centre of the table; they were tastefully and sparingly filled with a light hand, and fringed with light Fern fronds. Springing out from these towards the finger-glasses, which were filled with choice flowers, were light, delicate sprigs of Ivy, so thin as to end in mere points of verdure. These were sparsely used, and the effect was charming—a perfect blending of lightness and simplicity. Strolling in an hour or two later, the decorators were still at work finishing—i.e., utterly spoiling their work. At the points where the graceful twiglets of Ivy vanished towards the finger-glasses a stiff continuous double line of Coleus leaves had been laid on the cloth; and all among the Ivy, Chrysanthemum blooms in

thickly-burred sprays of Holly and Mistletoe, supported with small bunches of leaves and sprays of Ivy of different colours? For rosettes on the table Christmas Roses and Camellias might alternate.

It is the taste in the arrangement, not the cost nor the mass of material employed, that tells in Christmas and other decorations; and it may be added that the higher and purer the taste, the more sparing of material, and *vice versa*. A few touches of the pencil suffice the painter with genius, but the mere dabbler's brush is ever in motion between the palette and the canvas. It is very much so with table decoration. A few bold touches please, while a multiplicity of intricate details leads to confusion and disappointment.

And what is true of dinner tables and rooms is even more so of churches. The amount of "love's labour" absolutely lost on these at the festive season is appalling. Destined to be viewed chiefly from a distance, the greater part of the labour involved is seen imperfectly or not at all. Simple designs executed in durable material are by far the most suitable. Holly, Ivy, Mistletoe, Yew, Box, should form the staple, the warp of them all; while more perishable or scarce materials, such as flowers and berries, may be used more sparingly as the wool to show up prominently in inscriptions or designs. For the furnishing of fonts, &c., there is no more useful plant than the Ethiopian Lily in flower, used with abundance of its fine

leaves. It also has the merit of bearing the cold and draught of churches better than almost any other plant. Plants in pots, as Yews, Hollies, Cupressus, Retinosporus, Laurustinus, Euonymus, Box, Bays, Myrtles, Acacias, Gum-trees, &c., are also invaluable, as well as the more hardy Palms, Yuccas, Aloes, Ferns, &c. In warmer churches, Azaleas, Camellias, forced Rhododendrons, Lilacs, and any other greenhouse or stove plants may be used. Few plants are more effective than good specimens of Heath and Erica; while Chinese Primroses, Bouvardias, Cyclamens, forced Hyacinths, Tulips, Narcissi, and Crocuses furnish any amount of colour that may be needed. But to mix all these in one church arrangement would be to invite failure. Chrysanthemums are not named, as though several of the later Japanese and other varieties may still be in flower at Christmas, they seem to suggest a dead past rather than a joyous present or a hopeful future. This may be a

OUTDOOR PLANTS.

NYMPHAEA TUBEROSA AND ITS VARIETIES.

THE pure whitotuberosus Water Lily from North America is one of the most beautiful of the wild species known to cultivation. The plant possesses many good qualities that should commend it to all lovers of aquatic plants. It is hardy and free growing, succeeding well in open water in many parts of the British Isles, and produces its large white blossoms during the latter part of July, and from this time onward into the early autumn months. While perhaps it may be said to be less rampant than some of the newer hybrid kinds, it is yet a vigorous growing plant, and produces handsome leaves, each 12 inches across, or possibly more than this. The plant has not the thick strong fleshy rhizome or stem peculiar to a large number of Nymphaeas, but in place thereof

N. T. RICHARDSONI, a variety with very handsome pure white and very double flowers. The white of the petals is very beautiful, and not less so the globe-like symmetry of form. This is produced by the inclination to droop of the outer sepals and petals, while the way the flowers are held just out of the water renders it at once conspicuous. This latter kind appears in the illustration, and is not merely a novelty but a decided acquisition.

These tuberous forms of the Water Lilies may be increased by division, which in the case of plants of any size can be done at any time when the plants are dormant. Indeed, in this these aquatics are not very exacting, and we have taken them in full leafage and divided them when occasion demanded. All the same, there is some possible danger to the foliage at such a time, and for this reason the work is best performed when no such risk is likely. A depth of two feet of water is often found ample for the requirements of a large number, and

Nymphaea tuberosa richardsoni

mere fancy, and it must be admitted that Chrysanthemums last long and are showy in Christmas or other decorations. But a decoration of leaves and berries only is far preferable to one in which flowers already partially faded form any part. D.

Montbretias.—These corms, hailing from the Cape, are exceedingly useful for furnishing quantities of cut-bloom for table decoration, and, as they come into flower at the end of the summer and are not expensive, one is justified in planting them freely. They are best grown on a warm, well-drained south border—mine have done best in a similar position—they are sun-loving and not shade-loving plants, as some appear to think, from the numerous inquiries one hears of them. The corms are best taken up in autumn, when the foliage has dried, and re-planted in March, as, if left too long they become entangled and do not bloom so well. I do not suggest that they will not stand the winter, as, slightly mulched, they take little harm.—TOWNSMAN.

a rather dense mass of tuberous roots. Happily the plant is obtainable at a cheap rate, so there is little reason why it may not figure in all collections. Small plants of it are suited to growing in tanks or fountain basins, and in these latter are very pleasing when in flower. Including the typical species there are only about four kinds, but all of these are worth growing.

N. TUBEROSA has large white flowers some 4 inches or 6 inches across, the sepal and petal arrangement being much the same as in the common large white Water Lily and others. There is a delicate scent to the flowers which gracefully float amid the leafage and just clear of the water.

N. T. ROSEA, as the name implies, has flowers of an exquisite soft rose shade, large and handsome withal. This is a beautiful variety, worthy of a place in the most select assortment.

N. T. FLAVESCENS is a pale yellow variety, and is itself distinct by reason of the colour. But the gem of the group perhaps is

these among them. Loam of a heavy nature is the best, and with the root-fibres fastening on to the rich mud deposited at the bottom, a period of greater vigour and freedom of flowering is assured. E. J.

HARDY FLOWERING PLANTS FOR SHADY POSITIONS.

(REPLY TO R. J. CLEMENTS.)

THERE are many spots in gardens which, owing to their being in partial shade during the summer, are left in a state of neglect through the want of knowledge on the part of the owners as to what will succeed in such positions. The following list, which is based on actual experience, may therefore be helpful to such, as from among the plants to be enumerated a selection can be made, if there is not room to grow the whole of them, which will flower from May till the end of October. There are more subjects suitable for this purpose than many imagine, and there is no reason why odd corners, shaded portions of borders,

and the like, should not be made to look bright instead of leaving them bare and uncare for. The majority of the plants that will be mentioned, once they are established, may remain in position for several seasons, and, in short, they should be treated in much the same manner as are other herbaceous plants. Foremost of these are Aquilegias, which blossom as freely in semi-shade as out in the open, and from a packet of seed many beautiful and various coloured varieties may be had. The handsome *Doronicus* or *Leopard's Bane* also succeed well in partial shade, two good varieties being *D. plantagineum excelsum* and *D. caucasicum*. In a moist position a selection of *Trollius* or *Globe-flowers* may be planted. These are very handsome and flower early, good kinds being *T. asiaticus*, *T. europaeus*, *T. aurantiacus*, and *T. caucasicus*. A group of the *Lenten Rose* or *Helleborus orientalis* in variety, if planted where they will not be too much overshadowed in summer, will prove interesting in the latter end of April and early in May. There are some beautiful varieties among them, the colour of the flowers ranging from the pure white of *H. Professor Schleier* and *Willy Schmidt*, to the rosy-purple of *H. Inspector Hartwig* and *H. Gretchen Heinemann*. Spiraeas of such varieties as *S. japonica*, *S. astilloides*, *S. Aruncus*, *S. palmata*, *S. palmata elegans*, and *S. Umaria* (the *Meadow Sweet*) should also be grown, selecting a spot for all where the soil is inclined to be moist rather than the reverse. The *Canterbury Bells* of all colours make a fine show while in bloom, and each colour should be planted in masses. These must, of course, be treated as biennials, and a fresh stock planted where they are to bloom every autumn. Other species of *Bellflowers* which succeed in shade are *C. grandis*, *C. alliarifolia*, *C. glomerata*, *C. g. alba*, *C. g. dahurica*, *C. heticolor*, *C. persicifolia alba*, and *C. pyramidalis*. These are most effective when planted in clumps, and last a long time in flower. *Centranthus ruber* and its white variety are fine subjects for massing, and flower most freely, even when subjected to a considerable amount of shade, as will also the *Plantain Lilies*, or *Funkias*. The colour of the flowers of the latter are either white, blue, or purple, and there are a good many varieties to select from, but all of them may be employed for the purpose under consideration. A fine, stately-looking subject when in flower is *Crambe cordifolia*, and it does not mind partial shade. This, when in flower, reaches a height of 3 feet, the colour of the flowers being a pale creamy-white. *Telexia speciosa* is another tall-growing subject suitable for shady places, and so is the *Rosinweed* (*Silphium perfoliatum*), which also has light yellow flowers, and grows about 3 feet high. The *Day Lilies* (*Heimerlilis*) of such varieties as *H. flava*, *H. aurantiaca major*, and *H. Kwanso fl. pl.* may also be employed. To afford relief to so many of the yellow and orange-tinted flowers, *Lythraums*, in variety, will be found useful.

The *Willow Herb* (*Epilobium angustifolium*) will afford a mass of purple when in flower. This also needs a moist position. *Saponaria officinalis* (the *Soapwort*), and *Eupatorium purpureum* (the *Hemp Agrimony*), both afford purplish coloured flowers, and neither is particular as to soil and situation. The *Monks-hood* (*Aconitum Napellus*, *A. autumnale*, *A. pyramidalis*, and *A. japonicum*), all afford flowers varying from lavender-blue to purple; while *A. ochroleucum* has yellow, and *A. Napellus* almost white flowers. These are exceedingly fine subjects for semi-shade and remain in flower for a considerable period. Other suitable plants that may be mentioned are *Poxgloves*, *Liatris*, very handsome; *Aetna* (*Baneberry*), very pretty when in fruit; the *Mulleins* (*Verbascum*), particularly *V. thaxii* and *V. phlomoides*, *Tritoma Uvaria* (*Red-hot Poker*), *Monilactias* in variety; *Phytolacca decandens* (the *Virginian Pokewort*), very handsome when in fruit; *Göhlen Rods* (*Solidago*) and *(E)nothem Lamarekianum*. When room can be found for them *Polygonum*s (*Knotweed*) of such varieties as *sachalinense* and *amplexicaule*, the former giving white and the latter red flowers in autumn, should be employed. The different varieties of *Helianthus* and *Harpalum* should be accommodated if there is ample space at command, and in a few of the least shady spots some of

the more robust growing of the *Starworts* or *Michaelmas Daisies* may be planted. Lastly, there are *Cimicifuga racemosa*, with white feathery flowers, the three following varieties of *Helonium* (the *Sneeze-weed*), *H. mucronatum*, *H. grandicephalum*, and *H. striatum*, and *Chrysanthemum uliginosum*. A. W.

HOLLYHOCKS.

The Hollyhock needs a plentiful supply of rich food and deep soil to grow in, and it is well to trench the ground in time to allow of its being well exposed to the frosts of winter. Give a good dressing of rich manure, and if the ground has grown Hollyhocks previously, it should be freshened up by the addition of some good loam. A grower of my acquaintance used to trench the ground about 2 feet deep in November or December; a layer of manure was placed in the bottom of the trench and another layer 9 inches or a foot below the surface, but with the top layer was placed a good thick layer of loam from decayed turves, and at planting time in the spring some of this loam with the addition of a little manure was placed around the ball of roots and gave the plants a good start.

There are two classes of plants—*i.e.*, those raised from eyes or cuttings taken from the growing plants in the summer, and those from the flowers are expanded, and cuttings taken from the old plants in the early spring. An old stool will produce from three or four to a dozen growths or even more, and these if taken off with a heel attached in the spring will usually root well if planted in small flower-pots singly, plunging the pot in a gentle bottom-heat in the forcing house. The summer propagated plants are usually wintered in cold-frames and they are always well ahead of the spring-struck ones. The latter also bloom later; usually two or three weeks between their time of flowering. This is important when the object is to obtain good single blooms or spikes for exhibition, for if the lower flowers are gone, they cannot do much good on the exhibition table. In order to obtain good cuttings in spring, the old stools must now be taken up and potted. Eight-inch and 9-inch flower-pots are quite large enough. The plants are placed on a shelf not far removed from the glass roof of ainery or Peach-house. The frost is merely excluded by a fire during sharp frosts. The disease if it is amongst the leaves does not spread much in winter, not until the cuttings are placed in heat, when it spreads rapidly. The single-flowered Hollyhock is not much admired, but we saw during the past season some fine plants in a cottage garden; the spikes tall and well flowered and producing an excellent effect. The florist goes in for the largest, fullest flowers he can get and would not grow the single-flowered varieties. The single-flowered *Dahlia* is now very popular, so also are *Roses* with single flowers. One day single-flowered Hollyhocks may become popular, but we may admire both without favouring too much the one or the other.

THE BEARDED PENTSTEMON (P. BARBATUS).

This lovely species is much more beautiful than many of the named and so-called improved florists' varieties of *Pentstemon*s of the present day. If its merits were better known it would certainly be much more extensively grown. In July, and through the greater part of August, it produces an effect that is brilliant but refined, the graceful beauty of the plant being not the least of its charms. It does not make a bushy plant like the *Pentstemon*s that most people are familiar with, but its shoots cluster in a tuft upon the ground. The flower-spikes reach a height of from 2 feet to 4 feet, but nevertheless are strong and self-supporting. The flowers are from 1 inch to 2 inches in length, of a pretty coral-red colour, and most profuse upon the spike. Success with the plant, however, depends upon the observance of certain details of culture. It must not be planted and left to take care of itself, as many hardy plants are. The probability in such a case is that the old plants will get weak and die. On the other hand, it resents disturbance at the root. The plan is, when the plants go out of flower, early in September, to pull away some of the sides

shoots, some of which have roots attached, but this is immaterial, and pot them singly into small pots, and place them in a cold-frame. Here they remain all the winter, and by spring they have plenty of roots, and can then be planted out at a convenient time and in any desired spot. It also ripens seed freely, and can be raised easily. There is a variety of it named *Torreya* which has taller flower spikes, and the flowers are of a deeper red colour. This plant is also known as *Chelone barbata*—in fact, in nurserymen's catalogues it appears more frequently under this last name than that of *Pentstemon*. It is called the *Bearded Pentstemon* in consequence of several hair-like growths upon the petals near the mouth of the flower.

NOTES AND REPLIES.

Sowing Grass seed.—In preparing a new lawn the seeds have not been sown sufficiently thick. Would you sow additional Grass seeds in the spring, and what would you put on to enrich the soil?—R. J. CLARKE.

(In the month of April dress the lawn with a mixture of lime, wood-ashes, and some rotten manure put through a sieve to clear out all the rough matter, and then sow some Grass seed on it. Take care that the seed is not from a hay loft. If birds are troublesome, you should protect in some way.)

New Zealand Flax (*Phormium tenax*)—Have very fine plant in my garden here, 12 feet to 14 feet high. It was planted some ten years ago, and has never to my knowledge been sheltered at all. *Camellias* flower freely here, I may add.—Col. A. COLLINS, G.R., *Hughes Island*.

—In New Zealand this flourishes in a mean temperature of about 61 degs. on black humus in swamps or sandy loam or loam. In England it stands the winter well in southerly aspect, at *Haying Island* and *Weymouth* it should be protected when exposed thermometer reaches 22 degs. or 21 degs. At Falmouth it has a climate the most suitable, but lacking sunshine for blooming.—J. L. *South Haying*.

The herbaceous border in winter.

—Where many herbaceous plants are grown, the autumn is regarded as the best time, generally speaking, to tidy up and cut away any superfluous stalks, etc., also to make divisions where necessary. Those who could not do what they wished at that time will be best advised to leave the matter until spring, when plants are beginning to grow. It is a practice to be deprecated just to folk over such borders in winter, for, in the absence of tallies, one is almost sure to disturb something that ought not to be meddled with unless one is blessed with a particularly good memory; but, beyond mulching the borders now, any further work should be left until spring.—LEAUFEST.

Grasses.—Ornamental Grasses do not, as a general rule, play a very important part in gardens. We are rather more inclined to view Grasses of any description as intruders, and pull them up before they can flower, but some of the more delicate kinds, when used in the make-up of *Sweet Peas*, *Poppies*, etc., impart a gracefulness to the arrangement, especially sorts like *Agrostis nelulosa* (the *Clond Grass*), *Briza gracilis* (the common *Quaking Grass*), found in meadows, or the larger form *B. maxima*. But quite apart from their value in summer, they are useful for winter decoration, and to grow a bed, say of about 4 square yards or 5 square yards, one may get a collection that will serve a useful purpose from November onwards. Here are a few *Stipa pinnata* (long white Feathery Grass), *Hordium jubatum* (*Squirrel-tail*), *Eragrostis* (*Love Grass*), *Coix lacryma* (*Job's-tears*), are a few that deserve to be grown. Seed should be sown in April for blooming and gathering for the following year, and the stalks should be cut their full length when ripe, and not allowed to remain longer, drying them in the sun.—TOWNSEMAN.

Rhodanthe Manglesi.—It is impossible to over-estimate the value of this useful annual to the amateur with a small greenhouse in spring, where a moderately warm temperature can be kept up. *Rhodanthes* are easy to grow, and if seed is sown in February in shallow boxes or pans of loam and leaf-mould in which some coarse silver-sand is mixed, kept in the propagator, or near the pipes, germination will soon take place. Subsequently they will need potting off into pots of a handy size—say 3-inch—each containing fifteen to eighteen seedlings; these, as they grow, will need some slight support to prevent the stems swaying over, and cut two or three twigs to each pot, around which

allia may be entwined, will keep them in position. *Rhodanthe Manglesi*, the pink form, seems the more popular, but I think the white blossoms of *R. alba* are quite as effective. Both should be cultivated where graceful blooms are wanted for window or table.—TOWNSEMAN.

A FINE CACTUS DAHLIA—IDA.

Of the variety we figure to-day we have a deeper and purer yellow than in Mrs. Edward Lawley and Mrs. J. J. Crowe. It also comes into bloom before these. The flower is of true

parts of New Zealand which I have seen, and, I believe, flourishes (though it is more stunted) in the higher and colder regions among the mountains and fairly near the snowline. It grows to a considerable size; I should think the flower stalk often reaches 6 feet or 8 feet in height.—A. H. HORDHOUSE, *Rubiford*.

Scillas.—The frequency with which *Scilla sibirica* is referred to as the early *Scilla* almost leads one to suppose that *S. bifolia* is entirely overlooked as one of our first flowering bulbs; indeed, oftener than not it may be seen blooming in advance of *sibirica*, and should be

INDOOR PLANTS,

HYACINTHS IN POTS AND GLASSES.

A GENTLEMAN having kindly undertaken to furnish the bulbs, I was the other day invited by the committee of an adult school in Kingston to give to the members amongst whom the bulbs were to be distributed a brief address on the proper treatment of Hyacinths in glasses and in pots for domestic culture and decoration. The suggestion was a particularly pleasing one, and the large attendance showed

A new yellow Cactus Dahlia—Ida. From a flower sent by Messrs. Barrell & Co., Cambridge.

of cactus shape, the plant of good habit and very free blooming, reaching a height of about 3 feet. It is an acquisition to the yellow blooming varieties. It was raised by Messrs. Barrell & Co., of Cambridge.

Phormium tenax (p. 538).—This plant will stand a great deal of cold. It delights in a damp situation and deep, rich soil; in fact, it is a swamp plant. There is plenty of frost and cold in parts of New Zealand, but the country has much more sun and warmth on the whole than England has, so that plant life has a longer period of growth and absorption than in England. *Phormium tenax* flourishes in all

planted in the wild garden, and under trees—indeed, any place where it is not likely to be disturbed. This obtains in a large measure with many members of the *Scilla* family, but in particular *bifolia* does best when left to itself. Some years ago I planted bulbs of the common Wood Hyacinth (*S. nutans*) amongst Ferns in a corner of my garden, and as they have not been shifted more than once or twice, quite a colony of them blooms in May. The Spanish *Scilla* (*S. hispanica*) is also a favourite of many, and this, like the previous sort, is a May-blooming one, fitted for woodland walks, carriage drives, and places where once planting suffices.—E. L. YASSER.

how much interest the subject had aroused. Specially was interest abled because the results of the distribution, the culture, and the address were to be seen next spring in the form of a Hyacinth competition.

IN GLASSES.—For glass culture I took with me both the old tubular and the broad dwarf glasses, greatly preferring the latter as best and also as cheap, seeing that they can be purchased at from 2s. 6d. to 3s. per dozen. These broad glasses are in no danger of toppling over, and can be used as flower vases when not utilised for Hyacinth culture. With these was also an example of the brass wire support with a spring bow, so admirable for the pur-

THE HOLLY.

I suppose that Holly is chiefly associated in the minds of most English people with the interior of our houses and churches at Christmas time, when the bright scarlet berries, contrasting with the deep green of the prickly leaf, form such an agreeable feature in the decorations. As an ornamental shrub it is seen in gardens and parks, and it makes a very useful hedge, standing the shears well. Its straight shoots are cut from hedges and other places, and are unrivalled for making carriage whips, the branches, when trimmed off, leaving knots to vary the monotony of the long handle. Such is the Holly and its uses where the soil is rich. But where we come to light, sand, soil, in favourable situations, the Holly grows to a height of 50 feet or more, and is a worthy companion of the Oak in the forest. The timber it produces is very valuable; it is white, close grained, and hard, and of special use to the cabinet-maker, particularly for inlaid work. It is sometimes used for wood-engraving in place of Box; it also forms excellent handles for tools. Bird-lime is made from the bark. Within a mile from my house in South Hampshire are several fine Holly trees, some of great age. The girth of the largest is 4 feet 10 inches at the height of a man's chest. The tree, which is growing on a northern slope has a fine head. I find its height by measurement with the sextant, to be, to the summit of the crown, about 40 feet, and to the top of the bole, or timber-cylinder, 18 feet. The tree, however, if cut down, would be of little use as timber; there is a hole in the lower part of the trunk—the result of defective pruning, whether by nature or the hand of man—by which the rain enters, and I thrust my stick into a mass of black rot inside the tree. This rot must discolour the wood of the trunk, and in time will render the tree liable to be broken off by the wind when the Oak surrounding it have been cut down.

The habit of Holly trees to spring from all trunks is very noticeable in this neighbourhood, and the Holly stations, as I may call them, with light sandy soil on a slope where the sun does not get up to the roots, are no doubt of great antiquity, the trees on them being remnants of the primeval forest. The Holly, though omitted from some books on forestry, is nevertheless a true forest tree. It is storm firm, and I do not remember ever having seen a Holly that the wind had torn up by the roots. It is a misfortune that in many places this beautiful tree is ruthlessly mutilated for decoration. One word as to the cultivation of the Holly. Let its own leaves lie to rot on the ground and help to form a mould suitable for its growth. Evelyn says, "not dunging, which it abhors."—G. A. DAUBENY. *Tuckton, Christ Church, Hunts.* in "Nature Notes."

Desfontainea spinosa grafted on Privet.—This, which is alluded to by your correspondent "M. A. H.," is, if correct, most extraordinary, but my idea is that it admits of a simple explanation. I do not think it is the *Desfontainea* at all, but *Osmanthus ilicifolia*, a Holly-like shrub which belongs to the same natural order (Oleaceae) as the Privet, and at one time used to be often propagated by grafting on to its commoner relative. I have frequently seen the *Osmanthus* with shoots of Privet at the base, but the *Desfontainea* (which belongs to a totally different natural order) never. Again, the flowers of the *Osmanthus* are borne in the autumn, and are well described by your correspondent as being like those of the Privet, but in clusters, not spikes. True, the clusters are small, but the flowers themselves are sweetly scented. I do not know your correspondent's locality, but while the *Osmanthus* is quite hardy in England the *Desfontainea* is tender, except in particularly favoured spots, and it succeeds best near the sea. This, I hope, will serve to dissipate the mystery surrounding "M. A. H.'s" plant, but if any further elucidation of the matter is needed, a small spray of the prickly-leaved plant sent to the Editor of GARDENING ILLUSTRATED will be forwarded to me, and I can then at once determine the correctness or otherwise of my theory.—W. T.

pose required. A few pieces of charcoal, some water, and the bulbs, completed all that was needful for the glass demonstration. Bulbs in glasses should have the water taken from a main, or be very fresh rain-water, which should just touch their bases when placed in position. A small piece of charcoal in each glass does good. Stand the glasses now in a dark place where there is ample air until plenty of roots are made, then place them in the light as advised for the pot-bulbs. For

For culture I had one clean and one dirty 5-inch pot—the latter to show in what condition pots should not be used—also some compost, one half turfy loam the rest good decayed leaf-soil, old hotbed manure, some sharp white sand, and some crocks.

In showing how to pot Hyacinths, it was needful to make clear the nature of the drainage required, which need not be much when it is covered with portions of the coarser parts of the compost. The soil should not be too firmly pressed beneath the bulbs, as when throwing down roots if these do not freely penetrate the soil they partially lift the bulbs. The tops of the bulbs should just be visible above the soil. When the soil is moderately moist, as it should be, but by no means wet, it is unnecessary to give the newly-potted bulbs water. The best course now is to stand the pots on slates or boards beneath a wall or fence, and to cover them some 3 inches thick with either sifted coal-ashes from the house grates, or with Cocoa-nut-fibre refuse. This is done to exclude light for a time, as then root-action is all the quicker, and precedes leaf-growth materially. That is a matter of first importance. Where many bulbs are potted it is possible to take a few at a time from outdoors into a greenhouse or frame, and thus push some into bloom earlier than others. It is best to put them into a cold frame or greenhouse for a week at first, then shift them into moderate warmth. A sudden transference from a cold position to a warm one is often harmful. When Hyacinths in pots are to be flowered in a room window, the change from outdoors after the pots have become fairly full of roots into an ordinary room is trifling. In such places it is needful to stand the pots quite near a light south window, when they can have air, but not be exposed to cold draughts. A. D.

NOTES AND REPLIES.

Pelargoniums falling.—A disease has lately attacked by Geraniums, and my gardener cannot understand to what the cause is due. The cuttings, which were struck this autumn and seemed very healthy a week ago, are now looking in a very poor condition, all the leaves turning yellow and then falling off. The plants have been kept during the last six weeks in a lean-to house, newly built. The house has been heated with hot-water pipes, the temperature being between 45 degs. and 60 degs., but usually 50 degs. Fahr. I should feel very much obliged if you could inform me cause of disease and remedies that should be employed? There are about 2,000 plants in the house.—W. A. W.

[According to your note, the Pelargoniums seem to have been given suitable treatment, but, judging by the specimen sent, a better circulation of air would be an advantage. There does not, however, appear to be anything very serious the matter, as in many districts Pelargoniums of this class invariably lose all, or nearly all, of their leaves during the winter months. This is especially noticeable in the London district, as the sulphury fogs play havoc with the leaves, particularly if they are at all tender through having been kept rather too close or moist. We saw a house of plants the other day (it is true, in a less favourable neighbourhood than yours) which was simply a mass of bare stems, yet no uneasiness was experienced as to matters being righted with the return of spring. We observe that the bark of yours is in good condition, and have no doubt that before the month of March is over you will have no ground to complain. Give only enough water to keep the soil slightly moist during the winter, but fresh air should be admitted whenever possible.]

Lily of the Valley falling.—I enclose two specimens of forced Lilies of the Valley, and should be very grateful if you would kindly tell me the reason that so many of the bells have failed? The Lilies were lifted from the garden about three weeks ago, and have been brought on in heat in the usual way—i.e., in pots sunk in a hot-bed in a hothouse. I shall be very grateful for any information you can give me on the subject.—E. M. G.

[The reason of your Lilies of the Valley going blind, as per enclosed specimens, is that they

have been brought on too rapidly; indeed, it is very difficult to get home-grown crowns in flower by Christmas. The crowns that are so generally employed for early forcing are grown principally in the neighbourhood of Berlin, where they ripen earlier than with us, and consequently are less difficult to start into growth. This custom has been followed for a long time, but within the last few years the forcing of the Lily of the Valley has been completely revolutionised, and the splendid examples which are now so numerous in all the florists' shops of London are the product of retarded crowns—that is to say, those which, in the ordinary course of nature, should have flowered last spring, but, being kept frozen in large refrigerators, they remained dormant till they were removed therefrom and brought on in gentle heat, to which they readily respond. The advantage of using retarded crowns for flowering about Christmas time is that they do not require so much heat as the others, and, consequently, the blooms remain fresh for a longer period than those which have been hard forced, while the foliage makes its appearance simultaneously with the flowers; but in the case of the non-retarded ones, the flowers push up before any of the leaves. Of course, the retarded crowns are somewhat dearer than the others, as the erection of huge refrigerators and necessary machinery involves a considerable outlay.]

Heating apparatus.—I have a warm-water apparatus for my small greenhouse, consisting of boiler and 3-inch pipes, 6 feet and return, all made of zinc or tin. It is intended to be heated by a lamp burning petroleum, but it is inadequate and makes a great smell of gas besides occasionally filling the place with soot. All the apparatus is inside the greenhouse, and there is no chimney. Would it do to heat by gas with a "water boiler"—i.e., small gas-jet used for boiling water? I am aware that gas is supposed to be bad for plants, but the moisture from the water might mitigate the ill effects of the dry heat of the gas.—S. EDWARDS.

[We are of opinion that the best petroleum is less harmful than gas would be. From your remarks as to soot, etc., it would appear you have been using a cheap kind. This, however, would have little to do with its inadequate powers, to rectify which a stronger flame, or a number of them, would be requisite. This would be even so with the gas, and such drawbacks are ever present when the whole of the heating apparatus is within the house. Is there no possibility of altering this? For we see in any case, whether gas or oil, a larger flame power is necessary, and in this there is a greater possible danger than now. If you can place the heater outside the whole inconvenience is dispensed with at once; if you cannot, the only assistance in mitigating the ill effects will be by a shallow water pan on the heater itself, in any position, near enough to generate a little steam. This, and the keeping of floor and other parts fairly damp, are, we think, the most you can do. The purest oil may help you in the matter, and, as you are aware, the quality of this as well as the gas is extremely variable, and bad gas would, in its increased quantity, be quite as injurious as the oil. Our advice is first try the best oil procurable, and exercise care with wick and burner that these be kept clean.]

Campanula isophylla.—There is no better window plant in cultivation than this *Campanula*. It only requires ordinary care to bring it to perfection. The beginner in plant culture cannot do better than take it in hand, for it will yield a great amount of pleasure for a small amount of labour. This species is classed among hardy flowers, but it is only under certain conditions that it is satisfactory in the open ground. It must be sheltered from cold winds. The soil must be very free, the drainage perfect, and even then in a time of very hard frost the crowns should have some protection. This *Campanula* is easily increased by division, but on no account should the plants be divided before the young growths push from the crowns. If divided in a state of rest they are apt to die off.—J. C., Ryholt.

Request to readers of "Gardening."—Readers, both amateur and in the trade, will kindly remember that we are always very glad to see interesting specimens of plants or flowers to illustrate, if they will kindly send them to our office in as good a state as possible.

FRUIT.

APPLE LANE'S PRINCE ALBERT.

This is a grand Apple, and pretty well known to-day as a most prolific cropper, and requiring a free hand in thinning most seasons. In fact, unless this is carried out the growth would soon be unsatisfactory, consequently the variety is not much grown as a standard, but is found in most gardens as a bush or pyramid. I have heard some good gardeners condemn this as poor in flavour when cooked, but such is not my opinion. It is an exhibition fruit of no mean order when well cultivated.

DEVONIAN.

NOTES AND REPLIES.

Raspberries.—I have noted your many instructions with regard to Raspberries, but am perplexed as to the treatment of mine. I have two rows, put in singly last autumn. These bore well, but are still single canes, so that I cannot thin them as you advise. Should I cut them back or top them—they are about 4 feet high—and, if so, should I do it now or in the spring? I have others (old,

number of early kinds. I should not object to having two or more of good varieties. Would Cherries or Plums succeed on either wall as upright cordons, and if so, what kinds?—HURTE.

[The following varieties of Apples should succeed on the wall with a north-west aspect, and would give a succession of fruit well into midsummer. We do not quite gather what you mean by oblique upright cordons? Possibly your intention is to train cordons in an oblique or slanting position, so as to make the most of the wall space at your command. For late dessert plant at 18 inches apart 6 Cox's Orange Pippin, 3 Hubbard's Pearmain, 2 Allington Pippin, 1 Egremont Russet, 1 Claygate Pearmain, 2 Scarlet Nonpareil, 1 Lord Burleigh, 1 Fearns' Pippin, and 1 Sturmer Pippin. Cooking: 2 Beauty of Kent, 2 Lane's Prince Albert, 2 Bow Hill Pippin, 1 Mère de Ménage, 4 Newton Wonder, 1 Bramley's Seedling, 1 Alliston, 1 Old Winter Nonpareil, 1 Chelmsford Wonder, 2 Humbling's Seedling, and 1 Rymer 3i trees in all. Or if double cordons, half that number of trees. For the south-east wall

universal standard be adopted. Those conversant with Covent Garden understand sieves, half-sieves, bushels, and other terms, but in the country each district seems to have a method of its own. Here, in the west, it is very difficult to get purchasers to understand how many they are to have for a bushel, and if you use the word peck, then they want to know how much the Apples are to weigh. Only a few days ago a gardener, when purchasing from me, said, "I must have 14 lb. to the peck, or 56 lb. to the bushel." Before I agreed to this I put several kinds into the scales, and found that some would only go 12 lb. to the peck, while others weighed 14 lb. Large, soft kinds are light compared to medium-sized, hard kinds such as Ribston, Sturmer, etc. Personally I would rather Apples were sold by weight. This method is used by the men with the barrows in the London streets, and this is undoubtedly the fairest way. —J. CROOK.

Pruning wall fruit-trees.—I have some good Peach, Nectarine, and Plum-trees on walls, also Apple on espaliers in garden borders. My garden has not pruned or trained them in any way this year, and there are long shoots on all the trees, some on the Plums quite 4 feet above the wall. I should be grateful for advice as to present and future treatment?—CASA.

[As some of your fruit-trees have made shoots 4 feet long above the wall, it is evident that the roots are making far too strong growth consonant with the limited area your wall gives to the heads. Your best course is to have all these strong growths hard cut back, and then have trenches, 2 feet wide and deep, opened round in front of the roots of each tree, 4 feet from the stem, cutting clean off all roots there, and also grubbing under the roots with a sharp spade or broad, sharp chisel on a long handle, and cutting off all roots that grow downwards. That will check sap flow so far that the trees will not again throw coarse shoots, but will begin to form fruit-buds or spurs, and thus, a year later, become fruitful. This may seem to you to be drastic treatment, but it is absolutely needful if you wish the trees to be kept to their present wall areas. No doubt your gardener has realised that constant hard pruning yearly only leads to the production of fresh, strong wood shoots, and little or no fruit. If you will not take the course advised, then you must be content to thin out the shoots a little, and to just top those left, then let the trees grow out from the walls or trellises and become rather bushes than trained trees. Where roots are very strong, heads must have ample room. Gardeners who well understand the treatment of wall-trees as of others, constantly have to root-prune those which make too robust wood growth, sometimes in the way advised, and sometimes by unailing the trees from the walls, lifting them, pruning the roots, and replanting them. That process checks rank sap flow, and also helps to bring the trees into a bearing condition.]

Pear trees enkered.—Though I have annually root-pruned three Pear-trees that I have on Pear-stock, and applied the chemical dressing recommended by Mr. Rivers, they still continue to ranker. One bears a few Pears and the others do not. The trees are Napoleon Sarazin, Beurré Bachelier and Hardy (I am not sure which), and Marie Louise d'Orléans. Is there anything further that can be done to them?—HURTE.

[If root-pruning has not improved matters, we would advise you to lift the trees entirely, unless too large or old, and cut away all diseased wood and scrub with a brush, using soft-soap for the purpose. If you lift them see what the sub-soil is like—probably not well drained, a sure forerunner of canker. In that case it would pay to put broken brick-bats to the depth of 6 inches, allowing 2 feet to 2½ feet of soil for replanting the trees again, first putting some grassy turves over the drainage. The trees ought not to require to be root-pruned as often as you say. Are you feeling them too much, do you think, causing them to make far too much gross wood, and this, perhaps, does not get ripened well enough to form blossom-buds? We rather think this may be the fault of your trees. In that case do not enrich the soil when replanting. A little wood-ashes or lime rubble mixed with it would do no harm, and avoid too deep planting, keeping the roots as near the surface as possible, making the soil very firm and mulching with long strawy litter, and using the knife a little less for a year or two. Do not carry out this work when wet or frosty, but the sooner it is done the better for the tree.]

A good late Apple—Lane's Prince Albert.

but by ones), which the gardener has thinned to three or four canes to each stool, and cut back to about 3 feet in height, and tied to stakes. He has done this this week. Should it not have been done earlier or left till spring, lest the rain and snow enter the canes and split them? Kindly advise me.—PRINCE RASPBERRIES.

[Your gardener has done quite right. If your Raspberries, planted in the autumn of 1901, had done properly, there should have been a number of canes from the stools to take the place of those which fruited. Do you understand you to mean that the only canes are those which bore the fruit, and that no young ones have grown to take their place? You must understand that all the canes which bore fruit must be cut out. This is always best done immediately the crop has been gathered, so as to get the next year's bearing canes properly ripened.]

Cordons for walls.—I have a wall with a north-west aspect in my garden measuring 54 feet, on which I wish to train some cordon trees. I do not think Pears would succeed on this aspect. What dessert and cooking Apples would you recommend for this wall as cordons? I mean oblique upright cordons. Also what Pears would you recommend as oblique single cordons for a south-east wall 42 feet in length? I should prefer late kinds in each case, as I desire to have a

plant the following Pears, the distance apart is given above: 1 Doyenné du Comice, 2 Knight's Monarch, 4 Winter Nelis, 2 Easter Beurré, 2 Nouvelle Fulvie, 3 Josephine de Malines, 2 Marie Benoist, 1 Olivier de Serres, 2 Passe Crassane, 1 Doyenné de Alençon, 1 Président Barabe. Plums, also Cherries, would thrive on either wall, especially Plums on the north-west wall. Any of the cooking varieties should do well there, and probably Golden Drop dessert Plum if not too far north. Cherries are not much grown as cordons, but we see no reason why they should not succeed on the south-east aspect, choosing the sweet kinds that bear principally on the spur. The Mirelle is not suitable if heavy crops are looked for, as it is only by laying in young wood each year that this can be achieved, and with cordons this is impossible.]

Weighing v. measuring Apples.—Those who have to market Apples in different parts of the country have found how varied are the conditions under which they are bought and sold. I often think what a great improvement it would be could some

VEGETABLES.

AILSA CRAIG ONION.

The illustration which accompanies this note is that of a very fine lot of bulbs of Ailsa Craig Onion, averaging 1½ lb. each, sent me a year since, and which I got photographed. No doubt the bulbs lose something in size in the photograph because standing on a soft cushion. These splendid samples were the product first of carefully saved seed from other fine bulbs, specially selected to show deep globular form, solidity, weight, and brightness, then of a sowing made early in January in shallow pans, that were stood in a greenhouse near the light, and where there was gentle warmth. The seedlings some six weeks later were carefully lifted and dibbled out into shallow boxes filled with good soil, at 2 inches apart, then grown on in ample light and air to keep them sturdy, later got into a cool frame to harden, and then at the end of April planted out wide apart in well trenched and enriched soil, where finally these splendid bulbs resulted. A. D.

FORCING RHUBARB.

GARDENERS consider it pretty good work if produce can be gathered by Christmas day.

put to keep it dark and the wind from lowering the temperature. A pot of water and the syringe should be kept inside to damp the crowns each morning, and I may add there is no better place to force Seakale than here. It is an inexpensive shed, but will require a little repair most years probably as the boards soon decay. In May all the leaves should be cleared away from the boards; this, worked back in autumn along with straw stable-manure, will make an excellent heap of stuff to dig into the ground after being turned a couple of times. Rhubarb may also be brought forward by covering the crowns with boxes or pots made for the purpose and surrounding the same with heating material, made up of three parts leaves and one part stable-manure, throwing them into a heap for ten days before covering the crowns. The heating material should extend from 9 inches to 12 inches outside the pot and the same above, and test sticks should be stuck in and tried occasionally, for if it gets too hot the crowns would get burnt. Should the test sticks prove uncomfortable to the hand when withdrawn from the bed, the material must be pulled away from the crowns for a day or two, at any rate the top covering, replacing as soon as the rank heat has escaped. It is also a good plan to place a bit of wood an inch thick under the lid or covering of the pots for the heat to escape in

excellent flavour when cooked. Ideal is a Marrowfat, the pods borne in pairs and well filled, the Peas being of a dark green colour and deliciously flavoured when cooked. It is a fine cropper, and what is still more in its favour is its early maturing, as it is ready for use quite ten days in advance of William I. The next variety to claim attention is Duchess of York, and this came into use a week later than Ideal, and two or three days in advance of William I, both being sown on the same date. Duchess of York is a very heavy cropper, the pod long, well filled, and yielding from eight to nine dark green Peas which, when well cooked, proved to be infinitely superior to any of the round-seeded varieties for flavour. It has very distinct broad foliage, and grows to about 4 feet in height. It also gained an award of merit in 1901. The next, though not by any means a new variety, is an improved form of that old favourite main crop Pea, Dr. McLean. Several sowings of this were made, and a heavy crop of highly-flavoured Peas was secured in each case. The improvement on the old form of this Pea is in the slightly larger pod. This variety, as is well known, grows about 3 feet in height, and for superior table qualities no Pea can surpass it in its season. The next and last on my list is Autocrat, and this has now become such an universal favourite, that it is

Onion Ailsa Craig.

It can be had sooner, but it is generally of a spindly nature, and of little substance. For the earliest supplies it is best to raise the roots, and introduce into a temperature of 60 degs. to 65 degs. Rhubarb enjoys a fair amount of moisture, being kept quite dark for the produce to be blanched. Good crowns should be relied on for early work, placing some light soil over the fleshy roots, and if forwarded under staging in heated houses, large pots or tubs should be put over the crowns. Those having a properly constructed Mushroom house will have little difficulty in forwarding the crops, but where such a convenience is not at hand, a good plan will be found in having a little hut about 15 feet long, 5 feet high, 9 feet wide, using 1½ posts 7 inches square, 4 either side, and 4 in the centre, nailing rough 2 inch slabs around, except an opening on the south side to get in and out with a door, and over the top allowing a space of from 2 inches to 3 inches between each, so that when packed around with fresh leaves 3 feet thick the heat may penetrate where the roots are. On the top place some straw litter first to keep the leaves from falling in, and about the same quantity of leaves, treading all very firm, and over this a thick covering of reeds or wheaten straw to carry off heavy rains, while where the little door is a couple of bundles of straw should be

raised it gets a trifle too warm. Four to six weeks must elapse ere produce can be gathered under the latter method, it depending a good deal on the weather: the colder it is the longer before any can be pulled. When taking the stalks see that the centre growth is not broken off, or the supply will be lessened.

EAST DEVON.

THE BEST PEAS IN 1902.

AMONG the dozen varieties of Peas grown by me during the past season there were a few that were so satisfactory that a note thereon may be acceptable to many, particularly as the time for making out seed orders is drawing nigh. Beginning with the first earlies, or such as come into use early in the season, a first-rate dwarf variety named Harbinger, and a taller one, growing to between 2½ feet and 3½ feet in height, and named Ideal, are worthy of special commendation. Both are new, and received the distinction of an award of merit from the R.H.S. in 1901. Harbinger is somewhat like American Wonder in appearance, but superior to it in every respect, and is a wonderful cropper. As seen by me, when on trial at Chiswick, the haulm was literally loaded with pods, and it bore in the same satisfactory manner with me last spring. The pods are well filled, and the Peas are of

unnecessary to enlarge upon its merits here. This Pea, since its introduction, has been thoroughly tested: for it has had varying climatic conditions to contend with, both as to drought and the reverse, and through all has maintained its character as being one of the best late-cropping Peas ever introduced.

A. W.

NOTES AND REPLIES.

Savoy Cabbage and frost.—According to past experience, we may reasonably expect severe frost after this rainy spell. If so, many green crops will suffer. These may be preserved for a long time by selecting a dry day and taking them up carefully, not allowing them to get dirty, and laying them in so that they hardly touch each other, and so that they can be covered in severe cold with mats or anything loose to keep out severe frost.—J. CROSS.

Asparagus-beds in winter.—“Clean and manure beds of Asparagus in winter, silt in spring,” was the advice of an old grower, and if the former operation has not already been done, no time should be lost. This will mean the cutting away of the old stalks almost down to the crowns, or, at least, just leaving sufficient to denote the whereabouts of the plants, then give the bed a layer of good fat stable-manure. I say fat, as the winter rains will wash the nutriment to the roots. It will

not matter if over all some strawy material is placed, as in spring, when cutting commences, one may get about the bed and cut the heads much cleaner. This practice I have seen adopted in the Evesham district.—W. W. EASTWICK.

Turnip White Gem.—As a variety that quickly becomes fit for use this can be highly recommended. Sown on a south border the first week in February, roots were ready for pulling quite early in May. It is of oblong shape and excellent in quality when served at the table. White Gem is also admirably adapted for growing in a frame or brick pit on a mild hot-bed for earliest supply.—A. W.

Sutton's Globe Beet.—This is a first-rate Beet to grow for summer and autumn use, and obviates the necessity for growing and storing such a large quantity of the long-rooted kinds, as it can be had ready for table quite early in the summer. The Globe is a vast improvement on the older Egyptian or Turnip-rooted Beet in every way, and by making two sowings a supply of useful-sized roots can be had in first-rate condition from early summer till end of November.—A. W.

Garden refuse.—There are gardens in which, from October to March, apparently little or no interest is taken, and where vegetable refuse is left to decay, and useless matter remains about until seed-sowing time comes round again. That it is undesirable to neglect a garden entirely in this way many will admit, and where such as Cabbage-stumps, Potato-tops, etc., with weeds, which may have run riot, exist, it will be wise to clear the ground at once, putting the *chbris* into a heap with a quantity of unslaked lime, covering the whole with soil, and thus aiding speedy decomposition. This will be found useful for digging into the ground next spring preparatory to planting or sowing vegetables. All vacant ground will benefit by being turned over without further delay.—LEAFHUNT.

The Yam as a vegetable.—During the period of stress which our sugar-growing Colonies in the West Indies are passing through, pending the abolition of the foreign sugar bounties, the attention of the planters has naturally been given to other produce. In Barbados great success has been achieved in the cultivation of Sweet Potatoes and Yams of the very best quality, and an endeavour is now being made to introduce these into this country. The Sweet Potato is a cheap and palatable vegetable, but a good Yam is a positive luxury. During a long residence in London I imported several barrels every year for my own use, and out of the numerous guests who tasted them at my table, there was not one who did not highly appreciate them. I may add that here the flavour is even more delicious than in the West Indies, as butter, which is a vital ingredient to a well-cooked Yam, is so much better. I am returning to Barbados almost immediately, but any information on this subject will be given by Messrs. W. Pink and Sons, of Portsmouth, who are importing regular supplies. Receipts for various ways of cooking both Sweet Potatoes and Yams are sent out with every parcel.—HON. F. M. ALLENBYNE (Member of the Legislative Council of Barbados).

Big Brussels Sprouts are a mistake, and this year this has been forcibly brought to my notice. In a large patch of many names, some of sorts sent for trial are a delusion from the fact of their being more like small Savoy Cabbages. Although we have had scarcely any frost, these monsters are rotten in the centre. When gathering, I cut several open and found them in this condition, while the close, bullet-like types are perfectly sound. Added to this, these giants have no flavour compared with that of the smaller ones. Only recently I sent samples of both to a leading seed merchant asking him to try them, and he wrote me a few days since confirming my opinion. Some may say they fill the bush, but this is a lame argument. If the sprouts are taken from a stem of each type and weighed, it will be found that often the small hard ones are the heavier. Those who have to purchase them have to do so by weight generally, except in places like Bath, where they pull up and market the stems entire, a plan that I consider wasteful in several ways.—J. C.

GARDEN WORK.

Conservatory.—There must be a liberality of flowers at Christmas, and on to the New Year there should be plenty of Chrysanthemums. Growing these flowers for decoration is something like growing Apples for market. We do not want very many varieties, but we want them suitable for the purpose. It is never wise to discard an old kind till something better in the same colour and habit of growth has been obtained and proved. It will be wise also to look upon many of the new introductions with suspicion till they have been thoroughly tested. Many of the new varieties are destined to disappear in a year or two, and with very few exceptions the exhibition flowers are of no use for decorative work, and, of course, for conservatory work and cutting. We need not begin the propagation yet. February, or even March, will be time enough to take cuttings, but the strongest only should be selected. Whites, yellows, and bronzes are the colours most in demand. Begonias just now are very bright, and, here again, one or two of the old kinds are useful. *Fuchsioides* and *insignis* are useful hardy kinds. Of course there is always room for a good batch of *Gloire de Lorraine*. Its habit is graceful and free, and the flowers last well. The fragrance of *Mignonette* is delightful. Violets also, and Roman Hyacinths make sweet groups mixed with small Ferns. Now that the crowns of Lily of the Valley are rotting, the forcing becomes an easy matter, and one does not want to begin with the present season's crowns immediately they come to hand from Germany. Poinsettias, both the scarlet and the white, are useful, and are not difficult to produce where there is a good stove. The forcing business has been a great success with the Trumpet Lilies, and the same may be said of the herbaceous *Spiraea*, which does not appear to suffer for having been held back. Some of the newer forms of *Heliotropes* are flowering freely. Cuttings struck in spring and grown up quietly through the summer, pinched a time or two, are now very sweet, and look like lasting some time. Of course, the plants are in small pots, but are sturdy, and on a shell or stage near the glass. Cyclamens, Primulas, and Cinerarias are good amateurs' plants, and may now, when sown early enough, be nicely in flower. Then, besides these, which are usually grown in quantity, there are odds and ends of things which are not so common, but which always attract attention. A good specimen of the old *Cytisus thipes* is specially interesting, and the yellow-flowered *Genista fragrans* is now plentiful.

Stove.—Those who grow a few Orchids of the commoner types will probably have a few flowers now. Some *Dendrobium*s, including *D. nobile*, may be had in flower. *Cypripedium*, *Odontoglossum*, *Lycaste*, *Phajus*, and others will be coming on without much heat. Among other flowers not difficult to manage are *Thyracanthus rutilans*, several *Epiphyllum*s, *Justicia*, *Begonias*, *Plumbago rosea*, *Poinsettias*, and *Euphorbias*. The brightness or otherwise of many of the above and others depends upon their treatment, both as regards growth and ripening. I remember seeing *Thyracanthus rutilans* planted out in a small stove some years ago, and trained up a rafter, and when in flower during the winter the bright blossoms at the end of the thread-like stems had a very quaint but pleasing effect. The flowers were of no use for cutting, and that is probably the reason why it is so seldom met with. The amount of water required at this season will depend upon the fire-heat used. Plants in pots standing near hot-water pipes will dry very fast, and must be watched daily. There is no necessity for high temperatures now; 60° degs. at night will be quite high enough, and if the sun shines in the morning the fires should be banked up with ashes early. If the syringe is much used be careful about the purity of the water, or confine the syringe to the walls and stages.

Forcing-house.—Where early flowers and French Beans are required, this house will be full now of things coming on. Most interesting is the young growth at this early season of shrubs and flowering plants. Among the things which may be started now, if well established in pots, are *Azaleas*, *Rhododendrons*,

Spiraeas, *Deutzias*, *Roses*, *Lalacs*, *Diclytras*, *Lily of the Valley*, *Solomon's Seal*, *Laburnums*. Thorns the two last should be brought on quietly in a Peach house. The various forms of Ribes force well. Weigelas also are very useful and are nice for cutting, but should not be rushed. Honeysuckles of the common type force very easily and are very sweet. As I have often said, all these things require a season's preparation, except, perhaps, the *Rhododendron*. These are usually planted back in the beds after flowering, and others potted up which are showing plenty of buds.

Cucumbers in winter.—To keep these growing through the dull days requires care. The roots are the most important things to consider, and a good bottom-heat must be kept up. Seventy-five degs. to 85 degs. will give a good range, and between these figures no harm can come, and if the roots are healthy and vigorous, there will be fruit showing in plenty; but do not permit too many to develop if the plants are to pass safely through February. When the days begin to lengthen, Cucumbers which have been bearing fruit all the winter begin to feel the strain, and if the plants have been run out too much, nothing can save them, and under any circumstances young plants should be in readiness either to plant another house or to replant the same house. But where Cucumbers must be had in winter there should be at least two houses, or one planted early in September and the other planted towards the end of the year, to be prepared for all eventualities. For winter Cucumbers I should prefer two or three small houses. Top-dressings will be specially valuable now.

Pines.—Successions which are expected to start fruit early in the New Year should be kept on the side of dryness at the root now, not so dry, of course, as to injure the colour, but the growth should be staid by a partial withholding of water. All water used now, and, in fact, at all times, should be of the same temperature as the house. Plants in fruit should be kept separate from the successions, as they will require more heat, and liquid-manure can be given from time to time as required. Night temperature for fruiting-houses, 65 degs. to 70 degs.; successions, 60 degs. to 65 degs. A stock of good loam should be carted in ready for potting in spring.

Window gardening.—Very pretty are some of the hardy foliage plants, especially the gold and silver *Euonymus*es. In good-sized bushes they are useful for Christmas decorations. The silver and golden *Troscartes* are charming, and there is a golden *Periwinkle*, named *Viola elegantissima*, which is very useful when large enough to use for a basket or to droop from a bracket, and the best of those variegated shrubs, *Ivies*, *Vincas*, etc., they are hardy, and if the foliage fails, we can move them back to the cold-frame and bring in others without cost.

Outdoor garden.—Roll haws and wall- after frost. Common hardy Evergreens, such as Yews and Laurels, may be pruned if necessary, but where cutting down is necessary it will be safer to leave the work till March. The best Laurel for forming undergrowth in shrubberies and for planting on banks is the round-leaved variety, named in catalogues *rotundifolia*. It is much hardier than the common forms. The broad-leaved kind is also hardier and better than the common sort. In spite of the objection which has been taken to Laurels there is still a large demand for them, chiefly owing, I suppose, to their cheapness. For winter effect the best shrubs are Hollies. It used to be considered that the best time to plant Hollies was in spring, but I have moved Hollies at all seasons, and when well grown and kept regularly transplanted they move better than many other things. A group of golden leaved Hollies in the lawn in winter, either with or without berries, is always effective. *Aucubas*, when well berried, are effective and bright. To ensure plenty of berries we must, of course, plant the male as well as the female varieties. There are both variegated and green males, as well as females, with green and variegated foliage. Another race of *Aucubas* which is invaluable for winter effects is the *Tricolor*. There is a good deal of variety among these now, and the gold

and silver forms are very useful ornaments in pots for the cool conservatory. See that all standard Rosos are securely staked.

Fruit garden.—If there are any fruit-trees of an inferior kind, either in garden or orchard, of sufficient vigour to carry a new head the old heads may be sawn off soon, and left till spring for re-grafting. A vigorous old tree which has plenty of life in it may, when grafted with a good kind, have another long period of usefulness tacked on to it. The fruit-grower who wants to renovate his orchard and garden must be firm and resolute. Many an able, worthless tree is left to cumber the ground because of the conservative instincts of the nation. I believe in keeping all that is good and useful, but when a thing—tree or anything else—fails to pay for its keep, cut it down and re-graft, or grub up and re-plant. There is any amount of this kind of work to do before fruit-growing will be a satisfactory business, either for market or home use. This is a matter which concerns everybody. The Japanese Wincherry is no longer a novelty. It has proved a very useful fruit, and is quite hardy. The same may be said of the Logan Berry, which is not quite so well known, but is destined to become popular. Both are free of growth and will require some kind of support. The pruning consists in cutting out some of the old growths to make room for the young stems which are annually made. There is some pruning to do, which should have attention.

Vegetable garden.—The frost, though for the early season severe, did not last long enough to do much harm, but still, when the greens are in a very sappy condition, 20 degs. of frost cannot last long without inflicting injury. Personally, I do not want to see an old-fashioned winter; a long winter means terrible suffering, not only to the vegetables, but to human beings, especially those who never lay by anything for a rainy day. I never remember a time when so many men were out of work as now. This is doubtless owing to the men coming home from South Africa who have not yet found settled employment. With so much land only half-cultivated and so many men idle, the remedy seems to be in getting the men back to the land—but there is the difficulty. The deepening of the soil by trenching is work for the wintry weather, but if the soil is clayey do not bury snow or frozen earth where the frost has penetrated deeply. But the frost is a good pulveriser, and a rough surface, even if one has to break it up with a pick, has a beneficial effect. Seed potatoes for early planting should be sorted, and good sets placed in shallow trays or boxes that will just hold one layer when placed crown upwards. If the sides of the trays are made of lath to admit light the trays may be placed several deep, to economise space, or if studs are inserted in each corner of the tray 2 inches or so above the sides, the same object will be attained. E. HOMBY.

THE COMING WEEK'S WORK.

Extracts from a Garden Diary.

December 29th.—We make it a rule to thoroughly clean with soap and warm water all painted surfaces inside all plant and fruit houses at least once a year when the houses are not repaired. This is usually done during bad weather in winter. If a house requires to be repainted inside our own hands usually do the work when the house can be cleared. No great amount of skill is required to paint inside wood in glass-houses in working establishments where the principal object is to preserve the wood and clear out insects. Bulbs and other plants intended for forcing are now continually moving on from the cool-house to the conservatory, through the forcing houses.

December 30th.—Chrysanthemums which have done flowering have been cut down and moved to cool pit, to produce cuttings for later propagation. Of course, all strong cuttings are taken from time to time as they appear on the varieties required. We shall grow fewer of the big blooms and more of those useful sized flowers which are required for decoration.

and though from force of habit we never like to miss a good cutting, the bulk of our stock will not be inserted before the end of January and later.

December 1st.—In open weather we are busy training wall-trees. We like to see wall trees trained correctly. It is no more trouble and does not take any more time to train at equal distances apart and in the right direction than to nail the shoots in without any regard to system, and correct training equalises the flow of sap. Whenever the branches of a tree are crowded in the centre and the bottom of the wall badly furnished, the trainer does not understand his business, and should be turned loose with a spade.

January 1st.—We have made rough plans of kitchen garden and flower garden where bedding-out is carried out. In the kitchen garden each plot is marked out for a particular crop, and in the manuring and cultivating operations this plan will be under observation. Plans of flower gardens, with each bed marked with the name of the plant intended for it, help the propagator during the spring when providing stock, and we want to economise labour and yet have enough plants for each design. This season we have a better stock than usual of most things, and with the spring propagation the stock can be easily increased.

January 3rd.—Several old Apple and Pear-trees of inferior kinds have been headed for re-grafting. The Apricots on our south wall had become too crowded. One old tree was condemned and the others opened out, so that each might have more space to fill, as I dislike having to keep stalling back leading shoots. All Peach-trees have been unnailed, with the exception of enough shreds on the main branches to keep them in position. All Peaches are loosened from the walls and re-trained annually. This makes clean work, as every branch is washed before retraining.

January 5th.—We have been busy in the shrubbery with a part of our staff. Laurels used for undergrowth are kept low by annual pruning where the trees are large. We like to see the trunks rising out of the dark green foliage, and so the Laurels are kept low. Groups of Cedars with an undergrowth of Berberis Aquifolium are very effective. The Berberis is pruned every season after flowering, and this keeps it in condition, and it blossoms freely, and the young bronze-coloured leafage during the spring and summer is charming.

LAW AND CUSTOM.

Nuisance from ashes.—A heap of clean ashes is placed on private property on the roadside within the boundary of a town, and the inspector of nuisances has requested its removal. Similar heaps have stood there for over sixty years, and my neighbours raise no objection. Is the heap a nuisance? Can I be compelled to remove it?—*THIS.*

[A heap of ashes that contains neither night-soil nor any other refuse, and is perfectly clean and free from organic matter or dust, will not be a nuisance to health; but apparently the heap is in an urban district, and the bye-laws may provide for its enforced removal, whether it be a nuisance or not. I therefore advise you to comply with the notice. As the heap is apparently placed at the side of a highway, the highway authority may deal with it, irrespective to nuisances to health.—K. C. T.]

Agreement for tenancy of nursery ground. (*R. B. H.*).—The agreement you sent is a very informal document—apparently it is only signed by yourself and is unstamped, and it does not even mention the rent. It is practically worthless. As the place is heavily mortgaged, I should say your position is most precarious, and I advise you to consult a solicitor with the view of obtaining a proper agreement with option of lease for a term, and you should get the mortgagee to join in the agreement. If the solicitor cannot obtain such for you, your best plan will be to quit the place on July 31st next.—K. C. T.

Income tax.—Acting on your suggestion in your issue of November 22nd, I wrote to the surveyor of taxes, and I enclose you copy of his reply.—*NORTHWOOD.*

[In that reply the surveyor says that from your letter you appear to be the "statutory occupier" of the land, and he points out that you pay the local rates upon it, and that it is not a garden as commonly supposed.

not agree with him that you are the statutory occupier; but your payment of the rates evidently raises his suspicions. As the surveyor declines to correct the assessment your best course is to pay the tax when it becomes due, and to appeal to the Commissioners next year. You ought to have appealed this year, but it will pretty certainly be now too late in your district.—K. C. T.]

Compensation for glasshouses erected in market garden.—Last spring I took about 1½ acres of market garden on a lease for five years, and paid the outgoing tenant by valuation for Strawberry plants, fruit-trees, etc. If I erect some glasshouses in the garden, could I claim compensation for them when I quit? Or should I have to remove them?—E. R.

[If in your lease the holding is described as a market garden, or if it is stated therein that the holding is let to you as a market garden, or that it may be treated or cultivated as a market garden, you will on quitting be able to claim compensation for any glasshouses, etc., that you have erected. Your claim will have to be made under the Agricultural Holdings Act of 1900.—K. C. T.]

BIRDS.

Canary troubled with insect pests.—I have a canary which pecks itself till raw, and now has a large bare place on the back. At first I could see nothing, but with the help of a magnifying glass, see there are many insects, some red and some black. I have tried rubbing on a little ointment, which seems to give slight relief, but was afraid to use much from fear of poisoning the bird. Neither does it seem possible to rub it in properly on account of the feathers. I give a little green food and little or no tinned, the principal diet being Canary seed. I have put the bird into a fresh cage, and he often has a bath. I have not had him long. I shall be much obliged if you can tell me of a cure?—F. S. KNOX.

[An old or neglected wood cage is often infested with parasites, which cause distress and irritation to the inmate. You must scald the cage with boiling water, well scrubbing with strong soda and soap, and then rinsing with clear fresh water. When quite dry carefully paint every crack and crevice with Fir-tree oil. The mites upon the bird can be destroyed by dusting it with Pyrethrum powder. Paraffin may be used, and will do no harm. The bird must be gently but firmly held in one hand, and with a small camel-hair brush dipped in the oil touch it here and there whilst blowing up the feathers, using only a small quantity of paraffin, so as not to soil the feathers. If the cage is not very valuable it would be well to destroy it and put your bird into a new one.]

Canary (Wellingtons).—This bird must have taken a severe chill, resulting in inflammation of the lungs. At this season of the year cage-birds require great care in guarding them as much as possible from cold draughts and sudden changes of temperature. It is well to cover cages at night, allowing, at the same time, free ventilation without draught; to avoid hanging cages in windows, and to take care that a bird is quickly dried after bathing; to insure this its cage may be placed near a fire for a time. The bath should not be given more than twice a week during the winter, and the water should be made luke-warm, and removed soon from the cage to prevent the bird from wetting its plumage too much. In this case there was also inflammation of the bowels, which may be, likewise, the result of a chill, but sometimes it arises from partaking of diet of too stimulating a character. It would be well to put your other birds on plain diet, and supply them with a little freshly made bread-and-milk occasionally.—S. S. G.

Keeping tortoise through the winter. (*J. M. Young*).—On the approach of cold weather tortoises become very sluggish, search out a soft corner in the garden, bury themselves for the winter, and remain dormant, sometimes till the return of spring, although should there be a spell of mild weather, they revive, and take a little food. Unless the soil of the garden is very light and dry it would be well to put your tortoise in a hamper or box filled with hay or dry Moss, and let it pass the winter in a cool room, feeding it with a little bread-and-milk whenever it awakes from its winter's sleep. These little creatures are very fond of Lettuce and Dandelion leaves, and, being vegetarians, do not feed upon the slugs in the garden as commonly supposed.

CORRESPONDENCE.

Questions.—Queries and answers are inserted in Gardening Free of charge if correspondents follow these rules: All communications should be clearly and concisely written on one side of the paper only, and addressed to the Editor of Gardening, 17, Farnival-street, Holborn, London, E.C. Letters on business should be sent to the Publisher. The name and address of the sender are required in addition to any designation he may desire to be used in the paper. When more than one query is sent, each should be on a separate piece of paper, and not more than three queries should be sent at a time. Correspondents should bear in mind that as Gardening has to be sent to press some time in advance of date, queries cannot always be replied to in the issue immediately following the receipt of their communication. We do not reply to queries by post.

Naming fruit.—Readers who desire our help in naming fruit should bear in mind that several specimens of different stages of colour and size of the same kind really assist in its determination. We have received from several correspondents single specimens of fruits in naming, these in many cases being unripe and otherwise poor. The difference between varieties of fruits are, in many cases, so trifling that it is necessary that three specimens of each kind should be sent. We can undertake to name only four varieties at a time, and these only when above directions are observed.

PLANTS AND FLOWERS.

Improving a lawn (A. L.).—Lure all the weeds and bushes removed from the lawn in March, then topdress with a rich, light soil put on 1/2 inch in thickness. Sprinkle to a good seedhouse, stating the size of the lawn, state of soil, position, &c. On receipt of order a renora seed mixture will be sent, arranged in suitable quantities of Grasses and Clovers, which, if sown thickly, will make a good lawn for prospect in the summer.

Cestrum aurantiacum (C. A. R.).—For training pillars or rafters of a greenhouse this fine climber is exceedingly well adapted. It is an autumn-flowering plant, and one of the simplest culture. It should be started out in a bed of soil, well drained, and be cut back in spring. Thus treated, it will not fail to produce every autumn a profusion of rich golden blossoms long, drooping terminal bunches, which contrast finely with the deep green foliage.

Agrostis pulchella (C.).—This very pretty Grass is annual, and grows from 3 inches to 1 foot high. Sow in March at the end of May in small clumps on the borders or lower border, and, covered slightly with soil, it will grow freely and be very acceptable for cutting at a time when the beauty of many things outside is fading. It requires no more care than white growing as keeping free from weeds, and a few small stakes and netting placed round the clumps to prevent the soil from blowing it to the ground.

Plants falling (Cheriot).—We take it the failure of a Aspidium and other Ferns is due to the condition of the verandah, and particularly through not giving sufficient light from above. It can not be responsible for lack of light. As we read your letter we are not sure whether the root of the verandah is of iron. If so, the failure cannot be as stated, and must be due to some other and local cause—either too much or little water. The normal heat given should suffice in times of frost, but if the plants were very wet they may suffer materially. It is difficult to assign the true cause of loss without any material to guide us in such a case.

Potting newly-imported Azaleas (Amateur).—Many newly-imported Azaleas, after having been potted, and often placed in a cold house till wanted to bloom, and on cold and inattention to watering they lose their roots. Did you take the precaution, before potting, to cut the balls of soil were thoroughly moist? If not, it is at once explain the cause of failure. You may also green the plants thoroughly, soaking after potting and setting them in a warm, moist house, gently syringing them once a day until the roots began to work in the new soil, and taking care that the soil, by overwatering, does not get too wet.

Plants for forcing (Cheriot).—The lilies you mention would be quite rare now if placed in the greenhouse, but in the temperature named there would not be much forcing. Some Tree Carnations, and Tea Roses (liable would be of the first: Winter Cheer, scarlet; Scott, rose-pink; Hayleark, delicate pink; Utah, blue, crimson; Middle, Carl, white; Mrs. S. J. Brooks, blue; General Maceo, dark crimson; Mrs. Tho. Lawson, sea-magenta; Governor Roosevelt, crimson. Of Roses suitable, Souvenir d'un Ami, pink; Nipheles, white; Aberdeen Mornet, soft pink; Terrible Jardin, yellow; Liberty, scarlet, are all good. The Illinois candy firm may be left in the warm, moist house, but L. auratum could be potted out for examination. This should be done even if required only for flowering in the ordinary course.

Pampas Grass (Gynerium argenteum) (Henry E. Jones).—This plant varies from seeds, and is also variable in reason of the sexes, which are separated, one sex, either male or female, only on each plant. It is doubtful whether you would be able to obtain them in this way, but you may inquire of the best nurseryman. We have no knowledge of any firm keeping them as described. The variation of which you speak is no doubt due to the sexes, and it is the female which is the more handsome of the two, and likewise the more lasting. There are one or two varieties, as G. a. roseum, and G. a. aureum. G. variety with purple plumes. Apart from these, G. a. glaberrimum is a fine new species with silvery-rose plumes. Taking all in all, however, it is doubtful if a better all-round plant exists than the typical species in its best form.

Plants in frame (Cheriot).—Your frame is generally too hot for the things named, and for Violets, Cyclamen, Fuchsias, and Hydrangea. The Fuchsias may be shortened back if ungainly, but pruning generally should be deferred for a few weeks. The Hydrangeas must not be cut down, the points of the shoots are those giving the flower-trusses in due course. The temperature is right for bulbs if well-rooted, it not, it is too high, and 50 degs. to 55 degs. would be more

safer. In any case give plenty of water to the roots of all bulbous plants that are in a forcing temperature. In the position indicated you could ventilate day and night, and should do so if you are not able to modify the heat, as stated. The temperature you name would be quite right for bulbs potted in September, but not for those in November.

Scale on Rose-trees (F. G.).—The pest you find on your Roses is male (Coccus rose). To destroy it, spray or syringe with paraffin emulsion or Quassia extract, and soil-soap; or, better, sponge the wool with any of the above. In the course of a few days wash over again to make sure of killing any that may have escaped the first application.

Coke versus coal (J.).—Whether coke or coal be the best article of combustion in furnaces depends very much on the nature of the furnace and the heat that may be required. All growers or market gardeners have a range of houses, many of which are for forcing, and who have large, low furnaces, use Anthracite hard steam coal in preference to coke, as giving greater heat. For upright boilers, no doubt, well-broken coke is best, because it is less liable to bake or clog. If you want to keep up a greenhouse temperature only, we should advise well-broken coke, but if you want greater heat at night, then some well-broken hard coal may be added with great advantage. Coal gives the quicker and fiercer heat, needing rather more attention in stoking. Coke is rather slower and more enduring. So much depends, too, on the setting of boilers, and whether they are active or sluggish. That is as much as we can determine the matter for you.

Tuberous-rooted Nasturtium (A. Grover).—Tuberous-rooted flowers well against a wall, with either south-west or south-east aspect. In light, well-drained soil, where it should have an occasional watering in very dry weather. It will run up to over 8 feet high. Its tubers increase rapidly in the ground, but care should be taken to lift them before the frost has penetrated the soil. It should be planted out in the open ground, near a wall, and support should be afforded it for climbing. Protect it from wind, let it have plenty of sun, and encourage it to run up the wall through other climbing plants, or over rabbit-netting, and it will look well, with its orange and yellow flowers, through the autumn. The only difficulty in its culture is with respect to the preservation of the tubers through the winter, as they are inclined to damp rot in places where other roots, such as Dahlias, Gladioli, Begonias, etc., keep well.

TREES AND SHRUBS.

White Jasmine not blooming (F. L.).—This often occurs through overpruning. Nothing has been said as to how the plant has been growing, but if fresh, and it has been hard pruned, therein lies the cause. Pruning such as is necessary should be performed at any time during the winter months, but it should only consist of cutting out the weaker and unbranched shoots. The strong shoots should be left unshortened, or bare only their tips taken off, and then they will produce flowers the following season. If they are cut back they will be sure to break into vigorous growth again. Plants which are most neglected as regards pruning, such as those upon roadside cottages, flower the most freely.

Propagation of Hollies and Yews (Anon).—Cuttings of these strike only with difficulty, the usual method of propagating them being by seeds for the common kinds, and the others are budded or grafted thereon. Holly-berries should be gathered when ripe and mixed with a little sand in a cool, moist place in order to separate the seeds from the pulp. They may be sown in the spring in a sheltered spot out-of-doors. Most of the seeds will germinate the second year. When the plants are about the thickness of a lead pencil, they may in July be budded near the ground with the choicer varieties. The common Yew may be raised in much the same way. Cuttings of the Yew are not so difficult to strike as those of the Holly, the best way being to mix some sand with the soil of a sheltered border, press it down firmly, dibble the cuttings therein, and then cover with a hand-lid.

FRUIT.

Blenheim Orange Apple (M. J.).—No doubt your Blenheim Orange Apple-tree is old, and its roots have gone deep and wild. If you care to take so much trouble you can help it greatly by peeling a trench 2 feet wide and 20 inches deep all round the tree, 7 feet from the stem. Into that put some quite fresh, good soil from the vegetable quarters, mixing with it some half-decayed manure and a sprinkling of bone-meal. That will create new and active root-action at once. It also you would strip off 8 inches of the surface soil within the trench, give a good dressing of animal-manure and bone-dust sprinkled in with it, then re-cover with fresh soil, the effect in a couple of years should be very great in creating a crop of fine fruit. Moderately thin the head of the tree before doing anything to the roots. Also later well coat the stems and branches with hot lime-wash.

Putting in Vine-eyes (L. C. S.).—The beginning of February is as good a time as any to put in the eyes. Having selected your wood, cut the eyes or buds to about an inch or a little more in length—that is to say, about half an inch on each side of the eye. The best way is to put each eye singly into small 3-inch pots, which should have some broken crocks at the bottom, and then filled up with soil composed of one-half fresh turfy loam and one-half leaf-mould, not too rotten, and plenty of sand. When the pot is full, taking care not to press down the soil too firmly, make a hole in the soil, which should be filled with silver-sand. Place the eye on this, pressing it down until the top of the bud is level with the top of the soil. Plant in a hot-bed having a bottom temperature of about 55 degs. to 70 degs. The soil should be gently watered after putting in the eyes, and be kept moist, taking care that it does not become sodden.

Planting fruit-trees and Roses (Annual Subscriber).—It is not wise to plant fruit-trees or Roses when the soil is very wet, as if trodden down then it later bakes hard, and is bad for the roots. It is far better to do the work when soil is pleasantly workable, as it should be at this time of the year in open, mild weather. If the soil be very dry, then water should be given freely after planting is done, but it should be allowed to percolate through the soil gently, and not be at all trodden into. When the soil is dry it is a good plan to soak them well

in a tub of water or a pond before planting. When soil is very wet it is sticky, and, of course, moves in lumps. When it is moderately wet it will work freely, and will lie light and fine about the roots. Even in spring planting it is wise to allow the soil to settle gradually, especially if the roots have been well soaked before giving a soaking of water.

VEGETABLES.

Renovating clay soil (F. Cheriff).—As a rule, coal-ashes are the poorest possible material to put into garden soil. When coal of inferior quality burns to a white ash, it that be run through a sieve and worked into the ground some good may be done to such a stiff soil as yours in helping to keep it a little friable, otherwise it has little or no fertility. As you say your ground is full of wire-worm, we advise that you get gas-lime, spread it over the ground at the rate of three-fourths of a bushel per rod, break it well to pieces, let it lie for three weeks, then die it in. That should do great good. So, too, will a heavy dressing of soot dug in at once. Your soil rather needs gritty matter to help keep it open or porous, such as street-sweepings, which include plenty of horse-droppings. Ditch or roadside trimmings mixed with lime and put into a heap to decay are good. So, too, is straw-manure from a stable, rotted leaves, or decayed garden refuse. In spite of the thinness of the soil, break up the bottom soil and leave it there to improve.

Cucumbers (M.).—It was wrong to plant four Cucumbers into a frame 6 feet by 5 1/2 feet. Two plants would have been ample, and even these would have needed a lot of thinning, especially taking out non-fruitful shoots. You seem to have had rather too many fruits on the plants. Ten or a dozen set at a time on one plant would have been ample. To take off the lights in the middle of the day and water was wrong. It would have been better to have kept them on during the day, giving a little shade if needful, and water when required about five o'clock, shutting down close, as that generates a moist air, which the plants like. So much depends, however, on the nature of the soil employed, the character of the water, etc., that either of these causes might have led to the failure of your plants.

Planting Asparagus roots (Cheriot).—It is well that you have lifted your 2 1/2 feet deep trenches, on which you propose to plant Asparagus, with so much soft decaying material this early, as now it can settle well down before planting time. That should be with you early in April. If the material in the trenches has sunk, add some soil to the trenches before you plant. Whether the roots be two years or three years from seed matters little if they be strong, but if you find the three-year-old ones extra strong, then get those and plant them. Put in one row to a trench only, placing roots fully 18 inches to 20 inches apart in broad furrows from 4 inches to 5 inches deep. You must not rot that year of planting, and only very moderately the following year. The soil is usually some 5 inches thick over the roots, and the stems, when about an inch or two through the ground, should be cut carefully as low down as possible. For six people a handle of fifty good heads should be sufficient.

SHORT REPLIES.

Belle Isle.—You had better consult our advertisement columns.—T. Wroe.—Any seedman would procure for you White Elephant Potato.—R. M. D.—Of course, if the soil is dry you must water in the trees, but no need to do so if the soil is fairly moist. Never plant when the ground is wet and stinks.—Constant Reader.—In all probability there is not sufficient rise in the flow pipe to cause the water to circulate. If the pipes are dead level all the way round the house there will be no circulation.—M. M. McWilliam.—See reply under "Short Replies." In our issue of Dec. 24, p. 528.—J. L.—Apply to Messrs. W. and J. Birkenhead, Fern Nursery, Sale, nr. Manchester.—William Foster.—Sorry we know of no such places in the districts you mention.—Mrs. Hodgson.—See reply to "Suffolk" in our issue of Nov. 15, re "Raising Gorse." Apply to Miss Althorpe at C. 4, Quai de la Megisserie, Paris.—W. F. J. Burke.—Your plants are being spoiled by the fumes of the oil-ovens.—T. J. Goodlake.—We have had the same thing in our own ponds, and we do not find it unusual in Water Lilies. It disappears entirely in some seasons. We have had none of it this year.—Rugby Amateur.—You cannot do better than get a good plain saddle boiler, which, if well set, is both economical and efficient.—A. C. Riverhead.—Impossible to advise unless you can give us the name of the plant you refer to.

NAMES OF PLANTS AND FRUITS.

* Any communications respecting plants or fruits sent to name should always accompany the parcel, which should be addressed to the Editor of Gardening Illustrated, 17, Farnival-street, Holborn, London, E.C. A number should also be affixed to each specimen of flowers or fruit sent for naming. No more than four kinds of fruits or flowers for naming should be sent at one time.

Names of plants.—Thoa. Norway.—Skimmia japonica.—Mrs. J. M. Scarfe.—Leave very much dried up. Evidently a Fig, but impossible to decide without fruit.—O. Donnell at Bos.—1, Eucomyia japonica aureo maculata; 2, Betinospora pulchra; 3, Butcher's Broom (Ruscus aculeatus).—Mrs. L. C. Marshall.—Trichomanes reniforme.—R. Greenleaf.—Cotoneaster trigida.

Names of fruits.—C. E. Hill.—Apples: 1, Probably Norfolk Brauflo, specimens very poor; 2, Specimens insufficient.

Catalogues received.—Barr and Sons, 12 and 13, King-street, Covent Garden, W.C.—Annual Cash Clearance Sale of Bulbs and Cheap Offer of Hardy Perennials.—Sutton and Sons, Reading.—Amateur's Guide in Horticulture for 1903.—J. Veitch and Sons.—Catalogue of Seeds, Choice of 10000 of Chrysanthemums, and List of Carnations.

PHOTOGRAPHIC COMPETITION, 1902.

PRIZE AWARDS.

Class 1—SMALL GARDENS.

1st Prize—5 GUINEAS to Mrs. WARD, Chappars' Court, Parkbury.
2nd Prize—3 GUINEAS to Mrs. DUMAS, Rochdale, Waltham-on-Thames

Class 2—FLOWERS AND SHRUBS OF THE YEAR AND.

1st Prize—5 GUINEAS to Mr. S. W. FITZHERBERT, Byngdon, King's-road, S. Devon.
2nd Prize—3 GUINEAS to Mr. S. WALLACE, Lough Eske, Co. Donegal, Ireland.

EXTRA PRIZES.

Miss Stocks, care of Rev. J. Herriman, 117, Ditchling-road, Brighton.—Olearia Gunniana; Allthea frutex; Solanum jasminoides.

Mr. A. G. Lawson, 32, Ashley-road, Crouch hill, N.—Spray of Clematis montana; Rose Gustave Regis; Border of Astors.

Mrs. Kount Wero, Cotlands, Sidmouth, Devon.—Border of Michaelmas Daisies; Corner in Hanley Garden; Bamboos at Cotlands.

Miss Chichester, Arlington Court, Barnstaple. Snowdrops; A Fern-hank.

E. L. Bland, Woodbank, White Abbey, Co. Antrim.—Choisya ternata; Acanthus latifolius.

Mr. Thomas Taylor, Crowsley Park, Henley-on-Thames.—Spiraea arifolia; Rose W. A. Richardson.

Mrs. Leslie Williams, Swanwick Cottage, Bath.—Doronicums under Pear trees.

Class 3—INDOOR FLOWERS AND PLANTS.

1st Prize—5 GUINEAS to Mr. G. E. LOW, Clonway Hill, Dublin.
2nd Prize—Not awarded.

EXTRA PRIZES.

Miss Chichester, Arlington Court, Barnstaple.—Bougainvillea glabra; Streptocarpus; Pancratiums.

Miss Violet Barnard, 23, Portland-place, London, W.—Hibiscus radiatus; Stephanotis floribunda.

Mrs. E. L. Bland, Woodbank, White Abbey, Co. Antrim.—Zephyranthes carinata.

Class 4—FRUITS AND VEGETABLES.

Photographs not of sufficient merit to justify awards of first and second prizes.

EXTRA PRIZES.

Miss L. Hamilton, Clakthorpe, Wimplesmere. Raspberries; Dwarf French Beans.
Miss M. Bernard, 23, Portland place, London, W.—Plum Golden Gage; Dwarf Beans.

Class 5—GENERAL SUBJECTS.

PRIZE OF 5 GUINEAS to Miss Myra Nurse Dickens, Newells Cottages, Horsham, Sussex.

EXTRA PRIZES.

Mr. Thomas Taylor, Crowsley Park, Henley-on-Thames.—Clematis montana; Peonies in the Grass; View in the Wild Garden.

Mr. J. Hummel, 88, Salecot-road, Wandsworth Common.—Vase of Plumbago capensis; Vase of Godetia.

Mrs. Streetfield, care of Miss Newcome, Thurston Lodge, Thurston, Bury St. Edmunds.—A Mixed Border.

BLIND MAN'S BUFF

never seems to grow old or out of date. But the wise hostess, as she smiles at the youngsters, knows that after the romp they will require something cooling without being chilling, and so she has provided Chivers' Jellies for the enjoyment of her little visitors. Pure and wholesome and flavoured with ripe Fruit Juices they always delight the guests. They can be obtained in a variety of flavours in pint and quart packets of the Grocer. In the way of drink for the children's party there is nothing safer than Cambridge Lemonade. "It beats all" Chivers and Sons, Limited, Histon, Cambridge. First English Fruit Growers' Jam Factory.

"Globe Polish" Celluloid Balls

[SUITABLE FOR

PING-PONG OR TABLE TENNIS

12 for 6d., Post Free.

These Balls are in every way equal to the best Match Balls, sold at six times the price. They bear the same relation to other balls for the same purpose as does Globe Polish to other polishes, being much cheaper and more effective. All orders executed strictly in rotation.

RAIMES & CO., LTD., Tredgar-road, Bow, London, E.

Hollyring Stamp, patented.

Patent Greenhouse BOILERS.

- The special merits of our Boilers are—
1.—LONG BURNING.
2.—EVEN TEMPERATURE.
3.—NO TROUBLE.
4.—The Feeders being hinged can be pulled forward when desired, completely exposing fire-box.

In these particulars our Boilers are beyond competition.

Guaranteed Minimum Burning 12 Hours Without Attention.

It goes without saying that the large reserve of fuel in the Feeder insures burning for at least four times longer than is possible with ordinary boilers. Unaltered ory Boilers can be replaced in a few hours work without moving existing pipes.

EXTRACTS FROM LETTERS RECEIVED:—

"My gardener says he never had such a stove before, so easy to work, and does its work so well." "Does its work splendidly, and is certainly the least trouble of any stove ever had." "My number 'burgeo' 10." "The last No. 2 I had from you always goes 24 hours at a stretch." "I never look at it but once a day, and have a good even heat the whole 24 hours."

For prices, particulars, and Estimates for Complete Apparatus, apply

12 HOURS STOVE SYNDICATE, LTD.

66, VICTORIA ST., LONDON, S.W.

15"

FOR ROOKS, PIGEONS, RABBITS.

Single barrel, hammerless, breech-loading Shot Guns, converted from Government Rifles, and fitted to take 12-gauge CB shot cartridges; specially bored by an improved process for long range and great penetration. Unequaled for all long distance shooting. 15s. each. Double-barrelled breech-loaders from 35s. Air Guns, 12s. 6d. Walking-stick Guns, 12s. 6d. Alarm Guns, 7s. 6d. Send 3 stamps for Price List.—MIDLAND GUN CO., Bath-street, Birmingham.

RUGS! RUGS!—Giant all wool, 6 ft. long, 6 ft. wide, and weigh over four pounds. Guaranteed grey. They have been used a little. Much better than common grey. I will send one post free for 3s. From—H. J. GASSON, Government Bond-factor, Ryde.

BLUCHERS.—5,000 pairs sewn Army Bluchers, quite new; splendid leather soles. Will send one pair, any size, post free, 5s. 6d. Cash returned if not approved of.—H. J. GASSON, Government Contractor, Ryde.

12 6.—GENT'S MAGNIFICENT GOLD-CASED KEYLESS HUNTER; compact model, perfect timekeeper (warranted). Also fashionable 18 carat rolled gold DOUBLE ALBERT (diamond-set), 10s. 6d. Sent for inspection before payment.—MR. CARTHY, Patent-maker, 410, Archway-road, London.

"GARDENING" BINDING COVERS.—Covers for binding each volume of GARDENING from Vol. I. up to the present time are on sale, Price 1s. 6d. each, post free, 1s. 9d. each. Of all Book-sellers, or from the Publishing Office, 17, Farnhill street, Holborn, London, W.C.1.

HARTLEY & SUGDEN, Ltd., HALIFAX. WROUGHT IRON BOILERS FOR HEATING FOR HORTICULTURAL WORK. IMPERIAL BOILER. Catalogue on application.

THE DENNIS HEATING APPARATUS COMPLETE 58/6. THOS. W. ROBINSON DENNIS IRON WORKS STOURBRIDGE.

FRUIT.

SOME FRUIT NOTES.

That all fruit from garden and orchard has been harvested, there is time to reflect on the past season and its influence on the fruit crops. Never was there such a full and abundant promise of fruit as just prior to the time of flowering. Hopes were uttered, however, when, following the extremely cold spring weather, the embryo fruits fell thickly to the ground. Some districts and gardens fared much better than others, but, on the whole, there is a general air of affecting Apples, and this was also the case of Plums. Pears were more fully cropped indeed, so far as I can gather, there was a very good average crop everywhere, there being little to choose between one variety and another in their cropping. The Apple crop was a most variable one, some trees being thickly laden, while others were almost or quite bare of fruit. In our garden there was a very marked instance of the uncertainty of these fruit-bearing trees. The tree of Court Pendu Plat, called by some the "Wise Apple," by reason of its lateness in bearing, has a branch of the variety Wealthy grafted upon it. Though the tree is in the best of condition, the "Wise Apple" was entirely barren, while the single cordon of Wealthy was so well laden with bright and handsome fruit that it needed support. Cox's Orange, Ribston Pippin, Blenheim, Claygate, Armain, Roinette du Canada, Peasgood's Nonch, and Fearn's Pippin are some that with a bare very sparingly. Ecklinville, a most useful Apple for home use, maintained its character for regular cropping. This with me was not failed to give an annual crop for the last ten years, and often it has been heavy rather than light. Observation confirmed the opinion formed long since that the early kinds were more regular in their bearing than late kinds, because the crop is gathered in time for the tree to prepare itself for another year. With the fruit all gathered in, the opportunity, both with Apples and Pears, is now afforded, the grower of comparing individual varieties. Pears, more than Apples, are so variable in quality that no one garden can be found to suit all and every kind. In the fruit-tree qualities can be compared and notes made for future guidance. An important point in fruit growing is that both trees and fruit ought to be kept strictly under name. Unfortunately, however, this is a rule frequently violated. I have been in many gardens, and small ones in particular, where no effort is made to keep the trees true to name, and it invariably happens that inquiries are made among friends or visitors for names of fruits, when the blame attaches to the growers for allowing the names to be lost at the time of or just after they are received from the nursery. Many allow the nursery label to remain until the name is obliterated, and then when autumn comes round fruit is despatched to the Editor with the hope of its being named. In the bewildering number of sorts of almost all kinds of fruits, how is it possible for the Editor to be

able to correctly identify them? There are certain kinds that have distinct characteristics which can easily be recognised. There are others that even the most expert pomologist stumbles over, simply because differing soils, stocks, and treatment produce characters not in universal harmony. Quite recently I looked into the fruit-room of a friend, and found Pears much confused in storing. No less than three lots, kept carefully separate, were found to be one variety instead of three, and none bore a label to identify them. My plan is to keep a book wherein are written the name and number of every tree bordering the garden paths and on the walls. If I did not do this, how could I accurately keep the names of several hundreds of trees in my mind the year round for I find it quite as necessary to know the trees in their winter nakedness as in their summer dress. Recording the names by number in a book is much more simple and reliable than using labels, except metallic ones of large size. Wood labels soon perish, and small zinc or metallic ones are difficult to find when the trees are in leaf. W. S., *Trombridge*.

ROOT PRUNING FRUIT-TREES.

GARDEN trees, through the restraint brought to bear upon them by the annual course of branch pruning, are much given to grossness and its subsequent ally, barrenness. When the summer shoots are vigorous there is usually a corresponding strength of thong-like roots, and these two forces are strictly opposed to fruit bearing. Apples and Pears are those most given to these undesirable traits, and give the most trouble. This invariably comes from deep burrowing roots, which go down into the subsoil instead of remaining near the surface. While tree planting is still in progress, it may be useful to relate how effective is a barrowload of lime-rubble at the base of an Apple or a Pear-tree, placed at a depth sufficient to allow 18 inches or 2 feet of soil for the roots to move into. The dry lime-rubble prevents the roots striking downward. This was discovered in quite an accidental manner, and the one who provided a dry lime base did so not with the object which it proved afterwards to serve. Trees so treated never required root pruning, because the growth was never of so gross a nature as to call for it, and so long as this moderate summer growth continued, so long was a crop of Pears of good quality forthcoming. Lime-rubble is sometimes to be had easily enough, and many fail to realise its value. Lately I have procured several loads from some old demolished cottages quite six miles away. For mixing with the soil about fruit-trees and Vines this is far more valuable than fresh lime, direct from the kiln, because it is more lasting and slower in its action.

Root-pruning is laborious work, especially when the soil is very wet or heavy, but when well done there is no doubt about its value. Trees once well and carefully root-pruned last some time in a healthy state before a repetition of such work is needed. Often the most offending root is one that strikes down straight from the bole of the tree, and unless

this is cut through the severance of all other roots avails nothing, for the growth of the tree will be maintained with almost the same vigour so long as this root is permitted to proceed unchecked. As large a ball of soil as is possible should be retained with all available fibrous roots preserved. The more of these present, the better are the chances of an early crop. Large trees having but a few thong-roots to support them suffer badly when these are all severed, especially should the summer following be a dry, hot one. In any and every case it is advantageous to provide a mulch of some kind around the base of trees thus operated on as a means of conserving moisture, and a surfacing of manure about the tree stems helps to keep the roots active and fibrous. Should the state of the summer call for such aid, it is well to remember to give an occasional soaking with clear water, and the presence of a manure mulch will economise this in every way. Root-pruning I have found capital work for frosty mornings when it is too cold for light work needing less exertion. I have found that from trees with their roots deep in the subsoil, even if they fruit freely, neither Apples nor Pears satisfy, because disease spots develop in the fruit when they are on the verge of ripening, if not before, rendering them of no value, because decay so quickly sets in. To have good fruit, either of Apples or Pears, the roots of the trees must be active surface, fibrous ones, otherwise the crop will be much reduced in value. Some sorts are greater offenders than others, it is true, but even the best can be readily spoiled if the conditions are not right. This year great losses have been found in the Pear-room, due to the sunless summer, aggravated, no doubt, by the depth at which the roots have been working.

When dealing with trees in clayey soil, some additions calculated to make it lighter and more easily drained ought, if possible, to be provided. Lime-rubble, burnt ballast, leaf-mould, or even house cinders will each help to correct this when mixed with the staple soil about the roots. If some of the clay can be wheeled away and replaced with surface soil, so much the better, and in any case the soil replaced beneath the ball of roots should be made firm, so that when settled no fissures are encouraged. Poor soil, too, would repay a little well-rotted manure, bone-meal, or artificially compounded manure incorporated with it, and soil long occupied with tree-roots must naturally become impoverished. In this, however, moderation must be the rule. S.

NOTES AND REPLIES.

Pruning three-year-old Apple-trees.—I send photographs of three of my Apple-trees planted three years ago. They have not been pruned since they were planted. Would you advise their being done now?—*IN DOCK*.

[It is unfortunate that your standard Apple-trees were not pruned soon after being planted. The photos sent show how much of the branches left unpruned is now bare. Cox's Orange Pippin needs a taller, stout stake to draw the stem upright; then have three or four of the larger branches cut back one third their

length, to give the head something of a foundation. Henceforth it will only need thinning. Mank's Codliu needs a few weak branches cut clean out, and the rest cut back, strong ones one-third, weak ones one-half. The Duchess of Oldenburg will be better to have the shoots just tipped, and if you could insert a wooden hoop into the head to cause the branches to spread it would be better.]

Pruning Vines.—As soon as the major portion of the foliage has fallen the pruning should be done, as this reduces the chances of bleeding when the Vines start into growth in the spring. Supposing the Vines are trained on single rods up the roof, all side shoots or laterals should be cut back to one or two good buds. Sometimes the first bud nearest the main rod is small; if so, cut to the next bud, which, as a rule, is large and good and produces the finest bunches. If the side shoots have been too crowded, some of the weaker and worst placed may be cut clean away; 1 foot to 18 inches apart is a nice distance for the spurs or side shoots. If the Vines are

it was full of fruit, and I was told by the grower it never failed to give a big crop. Certainly it had one on it at the time of my visit. I could hardly have thought it would have made so fine a standard. The wood was short and produced the fruit-buds on long spurs. It never received any pruning, the free cropping keeping the growth in check. What astonished me most was to see so fine a tree growing in such a poor, hungry soil.—J. CROOK.

PLANTS AND FLOWERS.

ROOM AND WINDOW.

SOLOMON'S SEAL FORCED.

The refinement and delicacy both of form and colouring of this plant make it very suitable for the decoration of rooms. No plant is more easily forced or gives so much beauty for a little trouble. Six or eight crowns should be put into a 6 inch pot in October and kept in a cold-

gata) is one of the best of all room plants, and stands first in my selection. The reason is that the leaves are leathery, and practically impervious to dust. The flowers are very curious, not attractive, and produced on the surface of the soil. Loam mixed with peat is a good soil, and provide good drainage. After potting stand the plants in the greenhouse if possible to assist them to become more quickly established. A great fault is constantly repotting plants, which is not required. As a rule, in the case of such things as these, the less they are disturbed at the roots the better. A great check is imposed by this constant disturbance, and they never increase properly. It is essential to sponge the leaves frequently with tepid water to remove dust and dirt from the surface. Once a week at least this should be done.

INDIA-RUBBER PLANT (*Ficus elastica*) is the next best room plant for winter. It is not so useful nor so vigorous as the *Aspidistra*, as there is a certain objectionable stiffness about it, but it often thrives where it is impossible to grow flowers. A good loam and peat soil and a moderate amount of drainage must be given. But the most important thing, as in the case of the *Aspidistra*, is to sponge the leaves at frequent intervals to remove dust and dirt. When the foliage begins to turn yellow a little soot-water will be beneficial, but there is really little attention required, simply not to overpot or repot too often, and water very carefully during the winter months.

THE OPHIOPOGON is another good window or room plant, though usually kept in a greenhouse or conservatory. But it may be brought into the room, and its wealth of narrow green and creamy-white variegated leafage is very attractive, especially when set off by spikes of sapphire-blue flowers. It grows freely in an ordinary loamy soil, and when used in the greenhouse is very pleasing in a terra-cotta vase or window-box, so to say, on a greenhouse shelf.

THREE EXCELLENT FERNS for rooms are *Pteris cretica*, its variety *albo-lineata*, and *P. tremula*. I do not think it is possible to get a more useful trio, all being so vigorous, and not like the majority of Ferns, averse to cultivation in rooms. They succeed in ordinary peaty soil and greatly dislike an over-supply of water.

DRACENA INDIVISA is another useful plant hard to kill, and always fresh in aspect when the foliage is kept properly sponged, and in this small selection may be added the *Dave Palm*, *Corypha nustralis*, *Grevillea robusta*, the *Norfolk Island Pine* (*Araucaria excelsa*), very pretty when small and distinct in aspect, and the *Sedge* (*Cyperus alternifolius*) and its variegated variety, which require more moisture than any of the other plants mentioned. It is graceful, free growing, and pretty when stood on a small table so that its fanciful growth is in no way cramped. All the foregoing kinds I have grown for years in rooms, and during the winter especially they succeed better than anything else I have tried. F.

Solomon's Seal forced.

young, the leading shoot forming the main rod must be cut back according to the strength of the rod. When the growth is weak it will strengthen the Vine if only about a foot of young wood is left; but if strong, about 3 feet may remain, always cutting back to a bold, well-placed bud. When there are several rods attached to one Vine, each one should be 3 feet apart and treated as described above.

Pear Jargonelle as a standard.—That is an interesting note by "T." at page 503, and should be helpful to those who have failed in obtaining good crops from this, undoubtedly the finest early summer Pear. I am glad to see "T." pointing out the error many make in pruning it so severely. When I came here I found some old trees that had been very severely pruned. I let them have their way and all is well now. I have seen many fine trees pruned in this way, and because the Jargonelle is usually seen on a wall growers are apt to think it must have the knife. The finest tree I ever have seen is growing as a standard in the open garden at Weston Grange, Bournemouth. This is about 20 feet high and 15 feet across, and in the best of health. When I saw it some two years ago

frame till wanted for forcing. With a good supply of crowns batches may be brought on in a greenhouse temperature, so as to flower from the New Year onwards. With glass protection the leaves are more tender in colour and the stems rather slighter than when seen outdoors. It seems strange that such a graceful habited plant, which, with well-developed crowns, lends itself so well to hard forcing, should be so seldom seen. All who have plants of this in their gardens and can spare a few strong crowns should try it. If potted at once the plants will come into flower by the end of February or early in March. T.

GOOD ROOM PLANTS FOR WINTER.

AMATEURS are always inquiring the names of a few good room and window plants, particularly for the winter, when flowering ones from a greenhouse seem to quickly fade. One reason of so many failures is that they are bought from barrows, and these plants are forced in heat to make them sell. They look in the perfection of health, but, so to say, possess no stamina, and the change from the hot house to the dwelling-room is too great.

THE PARLOUR PALM (*Aspidistra lurida*) are

Achimenes.—For a warm-house, when one desires to make a display with hanging baskets, some of them should be planted with *Achimenes*. One of the prettiest basket arrangements I saw last year was in a Cucumber-house, where a home-made wicker basket had been planted with those showy and charming blossoms. They looked extremely healthy, and, perhaps, one reason was that the frequent syringings the Cucumbers had to bring about a moist atmosphere suited the *Achimenes* to perfection. —WOODBASTWICK.

Growing Spiraea in pots.—Who is there who cannot admire a well-grown plant of *Spiraea*, say *japonica* or *astilboidea floribunda*, carrying numerous spikes of bloom in spring? Those who would have their light and charming flowers in April and May need not at this distant date give up the idea, for clumps procured now, potted, and brought into heat six weeks hence, will come in useful. For table and window decoration it is questionable whether amongst white flowers there are any that command a larger sale than *Spiraea*. When growing freely they require an abundance of water, but until growth has commenced water should be sparingly administered. —LILBURST.

INDOOR PLANTS.

PELARGONIUM DAUMIER.

This which we figure to-day was raised by Mons. Lemoine, of Nancy, and is said to be one

better habit and a much more profuse bloomer. Its beautiful bell-shaped flowers of a bright yellow colour are produced from the axils of the leaves at nearly all times of the year. Abutilons are easily propagated from cuttings, which root freely at almost all seasons, although

furnished plants in 4 1/2 inch pots, which during the winter greatly assist in the decoration of the greenhouse and conservatory. The shoots from plants which have been cut back soon after they have done flowering form the best cuttings, which should be inserted in a sandy compost and kept in a close propagating frame, where they root readily, after which they should be potted singly in a mixture of fibrous loam, partly decayed leaf-mould, and silver sand in equal parts. To ensure free growth it is advisable to add a small quantity of some fertiliser to the above-named compost. When rooted, and until they are fairly well established in the pots in which they are to flower, the young plants benefit by being kept in an intermediate temperature, while in autumn a position in a low frame to which plenty of air and sun can be admitted is best, as it is necessary to ripen the last-made wood to favour the formation of the flower-buds. During their growing season the plants must be frequently pinched to ensure their growing into a compact shape. The last pinching, however, should take place not later than the end of July, or there is a danger of not allowing sufficient time for the formation of the flower-buds, especially if it should happen to be a rainy season. A temperature of 50 degs. to 55 degs. is that in which the flowers open best and are least likely to damp off. On account of its being subject to red-spider, Linum trigynum must be frequently syringed, and care should be taken that the water reaches the under part of the foliage. During the hot weather, from July to September, when the plants are best stood outside altogether, it is advisable to give them three or even four syringings a day, preference being given to rain water whenever procurable. After flowering the plants may be cut back and subjected to similar treatment, but it is preferable to propagate and grow fresh plants every year. If not pinched, Linum trigynum forms a straggling, unshapely bush, varying from 2 feet to 3 feet in height.

Spotted Pelargonium Daumier.

Linum tetragynum is another beautiful yellow flowering plant of shrubby habit, but it must be grown in a warm house all the year round. If we only judge by the outward appearance, we find that it has a great affinity

those struck in early spring are the best. They may also be considered clean plants, the only insect to which they are subject being the green-fly, which is readily destroyed either by fumigating or by syringing the plants, especially the underside of the foliage, where the vermin generally collects, with a weak decoction of Quassia chips, which leaves no unpleasant smell and is very effective.

Linum trigynum is the popular name for Reinwardtia trigyna, a neat-flowering plant of shrubby habit, native of the mountainous parts of the East India. Although of equally easy culture, this plant requires a little more attention than the foregoing, but at this time of the

FITTONIAS.

Fittonias are stove plants and in the heat found therein, they may grow in the greenhouse during the greater part of the summer and autumn, and bear in mind that they are extremely beautiful in appearance, having prettily veined and veined foliage, are dwarf and most useful for growing in pans and baskets, or in pots for the various stages, one sometimes asks the question as to whether they are known as much as they ought to be. Light loam and leaf-mould are the compost they need, the warmest part of the house, and a moist, gently shaded atmosphere. They strike very freely, and those who grow Coleuses or Begonias can grow these Fittonias as they are fine foliageed plants. LEAHERST.

Fittonia argentea.

THREE GOOD WINTER YELLOW-FLOWERING PLANTS.

Yellow flowers are not plentiful at this time of the year; anyone having an ordinary greenhouse or a cool conservatory may without difficulty have a grand display of Abutilon Golden Queen and Linum trigynum, wherever the temperature of a house can be kept at a minimum of 60 degs. During the winter, a third plant, the lovely Linum tetragynum, may with advantage be added to the list. Little need be said here about the Abutilon, as other varieties with flowers white, pink, and of various tints are well known and found in nearly every private garden where yellow flowers are in demand during the winter. Therefore, under a generous treatment and planted out in the border of a greenhouse or of the conservatory, either against a wall or as pillar plants, they produce in great abundance their lovely flowers, which are so well adapted for bouquets and table decoration.

year its flowers, of a rich orange-yellow colour, amply repay the cultivator for any extra care bestowed upon it. Linum trigynum is essentially a greenhouse plant, and does best in pots. It is easily increased from cuttings made in March or April, and these if properly treated form in the course of the season bushy, well

with the plant just described; indeed, the differences are mostly botanical, inasmuch as its flowers, as the specific name tetragynum implies, are four-styled; whereas those of L. trigynum are three-styled. As a decorative plant for winter it is of as great value as the other yellow-flowered plants produced in

Abutilon Golden Queen is a great improvement on the better-known Boule d'Or, being of

UNIVERSITY OF ILLINOIS AT

greater abundance, are disposed in large fascicle-like racemes at the summit of the branches and branchlets; they are of a very pleasing pale primrose-yellow colour, and often 1 inch in diameter. The plant is sometimes liberally covered with its delicate Convolvulus-like flowers. The propagation of

check. If you have sufficient head-room we should advise limiting the pruning to the removal of any exhausted shoots, as it is the main ones to which you must look for flowers. The blossoms of this *Passiflora* are about 3 inches across, and of a pleasing violet-purple hue, the crown of threads in the centre being very conspicuous, and in colour, violet banded with white.]

Scarlet Salvia.—Would it be possible for me to grow Scarlet Salvia for greenhouse decoration next year? I think I said before that our climate is cold, damp, and smoky, and the greenhouse slightly shaded by trees and shrubs contains a mixed collection. What would the treatment for Salvia be, and how and when should we begin?—MANNMAN.

[If you have any old plants place in a good, light position in the greenhouse—that is to say, a structure whose minimum temperature is about 45 degs. Give sufficient water to keep the soil slightly moist, but no more; indeed, the object is to maintain the plants in a quiet state till the spring, when young shoots will be pushed out freely. These shoots will strike without difficulty if taken off at a length of about 3 inches, dibbled into pots of sandy soil, and placed in a close propagating case in the

warmest part of the greenhouse. Of course, these cuttings must be shaded from the sun till rooted. When potted off pinch out the growing points in order to encourage a bushy habit, and, directly the roots take hold of the new soil, give plenty of air. Pot on as may be necessary, and grow in the open air during the summer, bringing them into the greenhouse in the autumn where they will come into flower. One thing to be particularly careful about during the early stages of this Salvia under glass is to see that the foliage does not get affected by red-spider, as it soon causes a good deal of damage. Too dry an atmosphere is especially favourable to the development of this pest.]

Brugmansia suaveolens.—I have a plant of above growing at back of greenhouse in narrow border, minimum night temperature 45 degs. with hot-water-pipes. The above plant is still in bloom to a small extent, but is losing its leaves. What I want to know is, when should it be cut back for encouraging young growth for blooming next year? And, further, does it matter how severely I cut it back? The "Encyclopedia of Gardening," page 98, says, "Cut or prune September—October."—ELAN WILLIAMS.

[The Brugmansia should be kept fairly dry throughout the winter in order to thoroughly ripen the wood. This will result in all the

old and exhausted wood, and cut back the vigorous shoots to within one or two eyes from their base, always, of course, bearing in mind that one object of pruning is to ensure as symmetrical a shaped plant as possible. With the return of spring more water may be given, and on bright days a syringing will be beneficial.]

OUTDOOR PLANTS.

GARDEN EDGINGS.

In large grounds where borders and flower beds are cut in a wide expanse of turf but few edgings are needed, but in the average garden they are a very important feature, though so frequently neglected. In the majority, particularly in the country, a Grass verge is employed. Anything more unsuitable, trouble some, and generally inartistic it would be difficult to find. It is usually from 1 foot to 2 feet wide, the width being largely regulated by the blades of the mowing machine. The unsuitableness of this Grass verge lies in the fact that, owing to the constant necessity for mowing, rolling, and trimming the edges, a flowering plants must be kept nearly 6 inches away from the edges of the beds, so forming a hard line; also the Grass gets soiled during gardening operations in the winter, and in summer it is often brown and worn from being walked on, unless the plan of putting hoops *à la* public gardens is adopted, a veritable cause of stumbling to the unwary. If there were Grass verges to the law, narrow beds that form my Rose garden, there would be a little over a mile of Grass edging to mow and trim every fortnight. Certainly no one can claim any beauty in a narrow strip of more or less ragged turf as flat between a flower-bed and a gravel path. Even where the turf is beautifully kept, close as velvet and with edges true, it is at least out of all proportion to the resulting effect. Of course, some of these drawbacks apply to beds cut in turf, but here the effect is better, besides which, when it is all Grass, people do not walk in one place, so that it is not worn, and one presumes a large enough staff to keep it in order and to see that the edges are not "broken down" by being trodden on. Whilst speaking of this most unsightly result of treading on the edge whilst soft, it is not every gardener who knows how to repair the quickly and well. Instead of cutting out the crushed section and adding mould under it, lift the edge, without cutting the turf, with a sharp spade slipped under flat, and insert a wedge of any old piece of turf cut to the size required. A pat or two with the spade will settle everything in place again, and there is no fear of sinking, like there is with loose earth, and, more important still, the edge is a firm turf. Box edging has nothing to recommend it, save "ancient use;" it is very troublesome some to keep in order, as it shows a great inclination to die out in patches, and it cost

A stone edging.

Linum tetragynum is not limited to cuttings only, as this pretty species produces underground suckers, by which it may also readily be increased.

NOTES AND REPLIES.

Abutilon Savitzki.—Abutilons increase readily if cuttings of half-ripened wood are placed in a bed of sand, beneath which hot-water-pipes run, or if dibbled into pots of sandy loam in February and kept under a bell-glass in a warm house. The one under notice is a charming variegated sort, very useful for grouping amongst plants in a conservatory, or for window and table decoration.—LEAHMIST.

Primula obconica.—I have a dozen *Primula obconica* in their flowering pots. The leaves all seem to turn yellow or have yellow blotches, and some of them decay right off. My greenhouse is only heated with an oil-stove, and is damp generally. I do air well when there is a chance. All the other plants do very well. Any information will be thankfully received.—F. R. COOPER.

[You are evidently keeping your plants too cool and damp. An intermediate temperature of about 50 degs. with just enough fire-heat to dispel the damp suits this *Primula* best.]

Greenhouse.—What should the autumn, winter, and spring (i.e., when we have fire) temperature of a mixed greenhouse be? It contains common Ferns, Maiden-hair, Oleanders, Geraniums, Azaleas, Rose, Heliotrope, Camellia, and in it we strike cuttings. It is divided in the middle. Should air be always admitted? I gather from a previous answer that it has been too damp and close for Marguerite Carnations.—MANNMAN.

[Maintain a temperature of about 45 degs., and when the weather is mild admit air. We conclude that your house is heated.]

Begonia Gloire de Lorraine.—Mr. Mayo grows this *Begonia* in quantity at Bilton, and I lately noted some fine plants of it. Many of these were from 18 inches to 2 feet across, and growing in 6-inch pots. Those in 48-size pots were equally good. The colour was good and the plants sturdy, and a mass of bloom. It is impossible to over-estimate the value of this *Begonia* for winter blooming.—J. C.

Passiflora triloba.—I have a plant of this in small hot-house with night temperature now minimum 60 degs. My plant has never blossomed, yet is about two years old, and trained close to glass on wires. I am keeping same almost dry now. Is this correct treatment, and do blooms come from it, or young wood? When should I prune, and how, to get bloom next summer? And should the plant be repotted, and when? It has now filled a pot 14 inches in diameter full of roots.—ELAN WILLIAMS.

[We should not advise you to repot it, as being now somewhat pot-bound it is more likely to flower next summer than if repotted, as this would probably lead to fresh growth instead of flowers. The soil should be kept moderately dry during the winter, but not enough to injure the roots, as this is done the plant takes some time to recover from the

An edging of Ivy.

leaves falling, but you need not concern yourself about that. Then, in the latter part of February or early in March the plant should be pruned. In carrying this out cut away any

grows bare at the base. Besides being a fine harbour for vermin, it is a nursery for weeds, particularly for Couch Grass. It also is a robber of the soil, and practically hides all

low-growing things behind it, and is stiff and formal. It was only in its place when Italian gardening was in vogue. Ornamental tiles are impossible, besides not fulfilling the prime necessity of being permanent, as they are easily broken, and the frost causes them to crumble. The only ornamental, useful, and cheap edging is formed by evergreen creeping plants growing over a stone edging that, once set, is no more trouble. Any stone will do. "The stone of the district," say the few writers on the subject, "sandstone blocks for choice, but on no account use flints, bricks, or clinkers." No one would who could get sandstone, but the question of expense rules the garden even more than elsewhere, and in a chalk district flints are the only stones available. These soon lose the raw, new look, and though they do not absorb water, they, at any rate, do not crumble. Bricks are bad for this reason, still they have the great advantage of taking up moisture like a sponge; a 4½ lb. brick, put into a pail of water for some hours, will weigh 9 lb. In a hot, dry position this is an advantage, as all moisture is absorbed, to be returned to the plants during heat. Clinkers are the last choice, but even these can be made possible by dipping them into a mixture of colour-wash with some sand in it. A dull red—the tone of red sandstone—is the best. If the edging is properly planted and well looked after there should be but little of the stone showing in from six to twelve months, so, if either of the last two must be used, the unsightliness will be but for a short time. Where well-shaped blocks of sandstone can be used, of course no one would try and quite cover them; but not so with "makeshifts."

which will push their roots down amongst the deep-laid earth under the stones, finding there, in even the hottest, driest weather, coolness and moisture; and as so many creeping plants

mean they go steadily on, flowering all the summer, but, when the cool rains come in September, they throw up 15-inch to 18-inch stems with six to twelve flowers. On

A box-wood edging.

throw out roots from their branches, if they get amongst ground that they like, it will be found that they will root into the fine gravel very freely, so keeping themselves secure over the stones.

An edging of white Pinks.

Whatever is chosen, or used, must be used with a real knowledge of "why." Quite two-thirds of the stone should be sunk in the ground. The reason for this is not so much firmness as to make a cool root-run during hot, dry weather, and a protection against frost and excessive moisture in winter. Sandstone makes an ideal stone for rock-plants, as it holds a great deal of moisture, drawing it from the ground even in summer. The Sandworts are quite independent of soil, if there is any sandstone for them to grow on; the lesser Saxifragas are the same. The best time to set the stone is when the bed is made, but if this is *in situ*, dig a narrow trench between it and the path, rather deeper than the stones are to go. Put in the bottom 2 inches to 4 inches of good gritty earth, setting the stones on to this, letting them vary in height from 2 inches to 6 inches above the level of the bed. At this time they should touch, or, failing this, a small bit of stone must be wedged at the back, otherwise the mould will wash through during heavy rains. Well ram some more of the gritty earth round the stones at the back, and some fine gravel in the front, or path side, even though there has to be a gutter, this care being taken because of the plants,

The plants that are suitable must of necessity be regulated by considerations of soil, climate, and position, besides the all-important one of expense. Where dressed blocks of sandstone are used, "border gardening" becomes a pleasure, second only to good "wall gardening," and is more than enough to occupy "the leisure" of even an energetic amateur, for in a large garden these edgings are measured by the mile, my before-quoted Rose garden having over half a mile, yet I count it small. To the much-to-be-envied owner of such stone edgings all things are possible. To the best of encrusted Saxifragas, fragile mountain Pinks, rare Primulas, colonies of *Ramondia pyrenaica alba*, lovely drifts of *Phlox*, there is no limit. There is no necessity for covering up all the "stone." Foremost come Pinks. Their soft grey-green foliage looks like bloom during the winter, and their flowers are ever welcome. Somehow I have become possessed of a Pink that is really marvellous. The "grass" is nearly as strong as in Carnations. In May the wide belt is white with big flowers like a perfectly-grown Mrs. Sinkins, a tinge of green at their heart. June transforms them into a white flower with faint red markings, but October finds them Carnations! I

October 20 I gathered a handful of perfect blooms. I simply dibble in the cuttings 2 inches apart, about September, as close to my flint border as I can. A year after the stone is hidden by a 12-inch wide belt. I have a run of 150 feet of this Pink. All of the *Dianthus* family are beautiful. Nearly all of the *Saxifragas* are good, but the Mossy and London Pride sections are the most useful. Of the former, *S. trifurcata* (the Stag's-horn *Saxifraga*) is, perhaps, the best, the old London Pride being hard to beat. Where a wide border is wanted, the giant-leaved *Saxifraga* (*S. crassifolia*) is unrivalled, as anyone who has seen it at Mentone will agree. Double Primroses, *Aubrietias*, *Auriculas*, *Primula denticulata*, *Violas* (the American vars., such as *V. pedata* and *V. cornuta*), Tafted Pansies, *Veronica rupestris*, the double white *Arabis*, *Lithospermum prostratum*, *Phlox*, *Hepatica*, *Sedums*, *Sempervivum* in variety, and *Gentians* are a few of the best. Not everyone has seen the Violet "California" as an edging miles in length. I saw it once, and have never forgotten it—an enormous Orange "grove" a couple of miles above Nice, the trees planted in large oblong beds, each with a foot wide border of this Violet in full bloom. Where a wider border is needed for shrubberies, the various *Ivies*, gold and silver-leaved as well as the plain, are good, particularly for cool borders, when *Snowdrops* are beautiful planted amongst the *Ivy*. Where a little trouble is not objected to, various half-hardy or deciduous species can be used. As an illustration, large pink *Oxalis* for the summer, with *Myosotis dissitiflora* for winter and spring, or *Anemone* and dwarf *Nasturtiums*. Dwarf bulbs make good edgings. All the *Scillas*, *Chionodoxas*,

Foam-flower (*Tiarella cordifolia*) as an edging.

Crocus, "species" *Hyacinths*, and the *Muscari*, *Triteleias*, *Sparaxis*, *Sternbergias*, and Autumn *Crocuses* are a few. A good edging for a sunny shrubbery is yellow *Alyssum*, with either *Parrot Tulips* or *Spanish Irises* planted

amongst it. Thrifts and Sweet Williams are good. For a fruit garden Alpine Strawberries and Violets are among the best, and the Thymes for the kitchen garden.

Darlish, S. Devon.

A. BAYLTON.

PANCRATIUM MARITIMUM.

As a constant reader of your valuable and helpful paper, GARDENING ILLUSTRATED, I venture to ask whether you or any of your readers can kindly give me any information concerning *Pancretium maritimum*? Early this spring a friend sent me some seeds, supposed to be the above. They came from Ajaccio, but were live or six years old. However, the gardener sowed them in heat and they all came up, he then put them in a cold-house, and in the summer placed the pans out-of-doors, thinking that the leaves would die down. This they did not do, so in the autumn he pricked them into larger pans, and now has them in a cold-house. The leaves are narrow, something like lawn Grass, but are thick, about 3 inches long, and in colour rather bright green. Can you kindly tell me how they ought to be treated; whether they will do out-of-doors, and at what age the seedlings may be expected to blossom? I shall be very grateful for any information, as I do not know the Lily at all, or of what shape, size, or colour the flowers generally are, or at what time of year the plants bloom?—A. E. K.

[As the seedlings are now pricked off, you had better leave them in the larger pans and transplant them again in early spring, when you should select the warmest site you possess, and there place a temporary frame wherein to plant the seedlings. Well planted they will be safe enough till at least three years old, or even four years old. Let your frame be about 1 foot deep, and give the light a sharp pitch to south or south-west. Make up the soil of the frame 6 inches above outside level, using old potting-mould, if no better material is available, and abundance of sand or grit intermixed. Make this firm and plant the small bulbs in shallow drills at a short distance asunder. Keep the small bulbs quite close to the surface, with what roots they have in a straight-cut trench. From your description of the seedlings you have the true plant; with age, however, the leaves will lengthen to 12 inches or 15 inches, and nearly 1½ inches broad. If you consider you are quite favoured in respect to climate it is possible this species may do in the open, with certain modifications. The bulbs should be buried 3 inches deep, and planted in a sunny bed of well-drained loam and plenty of sand; for example, a narrow border against a warm wall, though even here a glass-frame would be infinitely better for them. This species is less hardy generally than *P. illyricum* or even *P. equestre*. Both of these grow and flower in certain parts of England in the open, but *P. maritimum* less so.

What is needed in the case of *P. maritimum* even more than the others, we believe, is an absolute rest in summer, say from May to August, when growth appears, as a rule. The growing and resting periods are controlled chiefly by the treatment accorded. This also will be responsible for the bulbs arriving quickly or the reverse at the flowering stage. It is not likely, however, they will flower to less than eight years. Meanwhile, grow the bulbs as well as possible. Keep them in growth so long as the leaves remain green, and keep them without water entirely when the foliage is ripened off. And not merely without water, but airy and dry withal above. In brief, these very definite periods are the best means of cultivating these plants known at the present time. The time of flowering is generally early summer or late summer. We have had bulbs in bloom in the same frame, and therefore receiving the same treatment at both seasons. In positions where the bulbs receive water more or less continuously the plants remain evergreen, or nearly so, and may go on indefinitely without any attempt to flower, this being brought about best by the artificial method above stated. The species is by no means free or certain in its flowering, however.

The flowers are white and extremely fragrant. From nearly the centre of the bulb the flower stem issues and attains 15 inches in length or so, and at this level are a number of flower buds arranged in an erect umbel. The individual blossoms are composed of a long tube. At the end of this tube the blossoms open out after the manner of a single Tuberosa, much longer and larger, however, and more elegant in form.]

VIOLET CULTURE.

I HAVE seen various notes as to growing and watering Violets in gardening and other journals. My method of culture for both single and double varieties is as follows:—I take the young rooted runners that have not flowered from the old plants that have done blooming in April or first week in May, divide them into a border facing east or west, 9 inches apart each way, water them in well, and continue the watering throughout the summer. Never let them want for water at any time in their growing period. Keep them hood, not too deeply, and pinch all the longest runners from them. Syringe them in the afternoon of hot, dry days with clear rain-water, and occasionally mix a little soot-water with the rain-water; also, once every three weeks, use a little farmyard-manure-water with the clear water. If they are planted in some good garden soil, which has been given a dressing of cow-manure and soot, you will be rewarded with some good clumps by the end of September. At this time make your beds up for them in frames, using good loam, leaf-soil, burnt earth, soot, and a little bone-meal; mix well up together. Place in frame to a height that will allow about 2 inches space clear from the lights. Plant the Violets in this mixture 9 inches apart each way, water them in thoroughly, keep the lights off them night and day, excepting in wet weather; then run the lights over them, lifting them sideways, which will admit air top and bottom of frame. Mat them over to keep frost out, pick all dead, damped leaves from them, stir the surface with a label to keep Moss down; then I think the Violets will reward you with their sweet blossoms from October to April.

GIEL MANN.

East Hill Gardens, Portlamb, Brighton.

NOTES AND REPLIES.

Carnations.—I have some beds of Carnations planted out last spring from layers taken the previous autumn. They flowered very badly, but made plenty of healthy looking grass. Hoping they will flower better next year I am leaving them as they are. Should a top-dressing be applied? If so, when, and of what? Carnations usually do well here. Can the soil have been too rich?—MEXMAN.

[The only thing you can do is to sprinkle some fine soil among the layers, and if very thick thin them out slightly. You ought to have propagated a fresh stock from layers, as young plants are always far more reliable than old stools.]

A pretty aquatic.—Since my remarks on the Cape Pond Weed appeared in your paper I have received two or three requests for further information respecting this plant, and perhaps some of your readers may like to know that we have in many of our brooks and streams an indigenous aquatic well worth growing in tubs in our gardens. I allude to the purple Loosestrife (*Lythrum Salicarin*). In a tub I have had it throwing up fifty of its pretty racemes of flowers, about 2 feet high, and much admired by many who were not familiar with it in its wild state, and the autumnal foliage, of a reddish-brown shade, is also beautiful. Small yellow seeds are produced in abundance. Blue tits seem fond of these, and are often seen climbing up the sproys searching for them. The Loosestrife is perennial and requires no care in growing beyond seeing that the tub is well supplied with water, and the roots spread till they soon quite fill the receptacle.—A. B. HERBERT, Morden, Surrey.

The Peach-leaved Bellflower.—Amongst the many beautiful Campanulas, none are more popular than *C. persicifolia*, the Peach-leaved Bellflower, and for beds and borders it is largely grown, having a prominent place in not a few country gardens where hardy plants are specialised. This variety is often to be seen planted in rows, or grouped together as "second line" subjects, backed up in many instances by tall-growing Delphiniums, etc., and in June and July such gardens are always effective. The blue variety is possibly the least grown, inasmuch as the white sort is in greater demand where cut flowers are wanted, but both have their place in borders where hardy flowers are cared for. All Campanulas love a sunny situation, good soil well manured in the autumn, and need division about every two years. Some that I neglected to divide for several years became

weak in the centre of the clumps and died off in the winter, whilst plants in small groups from a biennial division bloomed much better. Many who grow Campanulas seem to think that they will do with any kind of treatment, hence one sometimes finds them planted in out-of-the-way corners, under trees, etc., but to get the best results from them they must have a sunny aspect, and, as stated, a rich soil. Old stools should be pulled to pieces in March, replanted in fresh positions, as, by so doing, one will get much stronger bloom spikes. We often forget how useful Campanulas are for pots, and for cool-houses they should be borne in mind. WINDHASTWICK.

New Zealand Flax.—I have just come across a query in your issue of 13th ult. concerning the growing of the New Zealand Flax (*Phormium tenax*) in the open air. As I have had some little experience with this plant, especially with the variegated variety, I beg to say that I have found that it may be safely planted out in this climate (Eastcliff, Bourne-mouth) if a little protection of litter or Bracken is given to it during the first winter. The leaves sometimes shrivel and turn black with frost, but recover again. It is very effective on a lawn. The common green "Phormium" is still hardier.—H. MORDEN BENNETT.

LILIES IN THE GARDEN.

THESE noble garden flowers have only within recent years been planted largely in the best possible way, and that is among shrubs. At one time they were considered suitable for pots only; but under these conditions the finest growth and bloom were never obtained. Planted in the open, however, among Rhododendrons they are thoroughly at home. We were once much struck by the appearance of *L. elegans*, or *L. Thunbergianum*, as it is more often called, planted among dwarf, dark-leaved shrubs, *Kalmias*, &c. The contrast of leafage and flower was rich and telling. We may make use of almost every Lily in this way, even *L. longiflorum*, which is often supposed to succeed only in a pot in the greenhouse.

L. ELEGANS is a splendid early Lily, while there are many varieties differing widely in habit and colour of the flowers. The tallest should be planted among the shrubs, and in large spreading masses there are always openings through which can ascend the stately spikes of brilliantly-coloured flowers, reserving the dwarf kinds, those that grow only from 1 foot to 18 inches in height, for the outside. Such varieties as the apricot-coloured *alutaceum atro-sanguineum* (deep crimson, height 1½ feet), *Van Houttei*, *fulgens*, *Prince of Orange* (orange), and *croceum* (crimson), are all of dwarf growth, and adapted for edging peaty beds filled with shrubs. In growing the Lily in this form there is very little trouble. The soil that suits such shrubs as the Rhododendron also agrees with the Lily, and the growth protects the tender rising stems in early spring, when, except for this protection, they would suffer from frosts. A top-dressing of manure each year will keep both shrubs and Lilies in vigour, but it must not be dug in.

LILIEUM TESTACEUM (Nankeen Lily), figured on p. 581, is a distinct and fine Lily that does well in the soil that will suit Rhododendrons. The best Lily, however, for planting in this fashion is *L. auratum*. The large masses of Rhododendrons on either side of the main walk are generally a picture of colour in autumn at Kew Gardens, the bold spikes of this Japanese Lily appearing in profusion, the flowers large, numerous, and finely-coloured, finer far than anything we can obtain in pots. It is under these conditions that the full beauty of the variously coloured flowers is obtained. The bulbs are in the soil that suits them, and the growth is screened from heavy rains, cold winds, and late frosts. Those who have no large clumps of shrubs to plant it in should choose a sheltered situation, not exposed to the full glare of the midday sun, and where the soil is rich and well drained. It will succeed in ordinary garden material, if this is well manured, but it likes best an admixture of peat and loam. The finest results with *Lilium auratum* have been obtained by planting it among Rhododendrons,

and when once established amongst them there is no need to disturb the roots for several years. Varieties of *Lilium auratum* are many. Rhododendros, or clumps of some kind, abound in every garden, but present a monotonous effect when their season of flowering is over, unless relieved by a rich display of bloom, as here advised. It relieves the scenery of tameness, and gives colour in the autumn. Some thought is now given to the autumn season of the year, and rich effects are gained by the free use of Michaelmas Daisies and Lilies. Writing of *Liliums* reminds us that the common

L. CANDIDUM seems to have recovered in part from the disease that threatened to obliterate it, and the finest results have been obtained through massing the clumps together. In one test of England garden that we remember, placed on the side of a hill and fully exposed, there were large colonies presenting a sheet of pure white, and very beautiful on a cool July day. Such an effect should be repeated in large places where there are ample scope and opportunity for bold breaks of colour. It is a common and miserable plan to dot the Lily row and there in borders. A single spike

gives little notion of the full beauty of several together; and if it is not possible to plant them among shrubs in distinct groups of some in large beds at the house. Two or three years ago we saw masses of the Swamp Lily (*L. superbum*, a truly North American species), and this was sightful. It is very tall in growth, fully 6 feet or more; the stems are purple in colour, in contrast to the gay flowers, borne in a terminal cluster. This Lily may be grown among shrubs, enjoys a peaty soil, and is charming itself.

THE CANADIAN LILY (*L. canadense*).—Orange and brown spotted flowers of this, borne on slender stems, are welcome in late summer, especially when appearing from amongst an overgrowth of shrubs. It succeeds well in shade, and should be made use of in parks and open places, which require colour in the declining days of summer. The Orange Lily, *L. auricum* and *L.*

ledeborianum are good garden Lilies, but the latter is best seen in northern counties or Alaska, where it is common in cottage gardens, and of finer growth than in more southern districts. Few Lilies thrive more fully than *L. Martagon*, the variety *dalmaticum* in particular. It is an exceedingly beautiful form, very telling when allowed to form a large clump, or establish itself in the wider parts of the garden. *L. M. album* is a valuable companion to it, and, like all the forms of the *Martagon* Lily, quite hardy, very free in growth and bloom, preferring shade, but not refusing to grow in the sunlight. There are a few groups that should be considered when planting Lilies in the open. Among these may be mentioned *L. pardalinum* (the Panther Lily), with stems rising to a height of 8 feet, and seen to best advantage with shrubs as a groundwork. *L. pomponium*, too, must not be forgotten, as also the forms of *lanceifolium*. The autumn is the season for these. They remain longer in bloom than any other Lily, commencing in September and lasting many weeks in full beauty. A gay succession is kept up by the forms of *L. riantum*, the earliest of which begin to flower in August, the latest lasting till the end of October.

ROSES.

SOME GOOD NEW ROSES FOR POTS.

PROBABLY old-established kinds, such as Catherine Mermet, Bridesmaid, The Bride, Perle des Jardins, will not be superseded as forcing Roses in our time, but the years 1901 and 1902 have given us some particularly good novelties that are steadily making their way to the front. One of the very best of recent novelties is

FRAU KARL DRUSCHKI, so well illustrated in GARDENING of Dec. 6. I should not so much recommend it for hard forcing, believing it to be a variety that will be seen at its best in a gentle temperature. One of the grandest blossoms we had last season was upon a specimen of this fine Rose. For market it will prove invaluable, especially where the American style of long-stemmed blooms is in request. It really seems as though Dean Hole would see what he prophesied when he referred to "our children's children plucking their snow-white Marie Baumann—pure as sunshine dancing on a white dove's wings." The form, perhaps, is scarcely so regular as in Marie Baumann, but

Mme. Hoste to be one of its first sports. The sturdy habit of all three should ensure them a place in the most select collection of pot-Roses.

MILDRED GRANT is a magnificent Rose, grand in petal and upright in habit.

PAULINE BERSEZ and PRINCE DE BELGIQUE are two fine additions to the Hybrid Teas, the one after the style of Mme. Cadcau Ramey, only flatter, and the other resembling Souvenir du President Carnot. They both come from a raiser who has given us some of the best Hybrid Teas in cultivation.

PERLE VON GODESBERG and DUCHESS OF PORTLAND are of the Kaiserin Augusta Victoria type, the former claiming to be a yellow sport, but as seen very little yellow is present; the other evidently a glorified Kaiserin, which will perhaps eventually take the place of the parent.

ROADRICE, when grown in heat, is very beautiful and highly fragrant. Its open flowers have a tendency to fade, but in the bud state there is no more beautiful kind than this one.

LADY BATTERSEA is perhaps seen at its best in the forcing-house, where its bright rosy-crimson colour and fine long stems carrying exquisite buds are very welcome. It is reputedly a cross between Mme. Abel Chatenay and Mrs. W. J. Grant, so that should be sufficient guarantee that the Rose is a good one.

MME. JEAN DUFFY I much like. It is a fine sturdy grower, with beautiful bold flowers of a rosy-yellow colour.

MME. MARIE CROIBER and WILLIAM ASKEW are evidently seedlings or sports of Caroline Testout, and, as such, welcome and distinct additions to a popular group.

ROBERT SCOTT has evidently come to stay. It is one of the few good novelties from the States, and it has the free-flowering and continuous habit of the true Teas.

SOLEIL D'OR is a Rose of remarkable individuality, capable of great things as a pot variety.

SOUVENIR DE MME. CHEDANE GUENOISSEAU should be good, if only to compensate for its long name. That it is good I can testify. It is a fine flower of a very bright red colour.

SOUVENIR DE PIERRE NOTTING at present falls far short of its reputation, but, notwithstanding, it is a Rose of great possibilities.

The above are the cream of the novelties of the last two years. ROSA.

NOTES AND REPLIES.

A long-lived Marechal Niel Rose.—This fine Rose is, as a rule, short-lived, but one occasionally meets with an exception. The first plant I ever saw of this with good blooms on it was upwards of thirty-five years ago, and the plant still flowers well every season. This plant is grown by Mr. Adams, a jeweller, in Sherborne. When quite a youth, and serving in a large garden near, my chief took me over to see it in bloom. This was the second year of its blooming. In the early part of this year, in a conversation with its owner, he told me it had bloomed abundantly every year, and, one year, when it was at its very best, he sold £8 worth of blooms from it, and this was not an exceptional crop. It is planted out in a lean-to house. At first this house had no heat, but now for some years it has been slightly heated. It is worked on the Brier, and where the union is made the scion is three times the size of the

The Sankeen Lily (*Lilium testaceum*).

certainly the shape of Frau Karl Druschki is very beautiful.

MME. ANTOINE MARI has been admired by all who have seen the Rose. It is one of the most distinct varieties we have had for many years. The raiser is M. Mari, of the Nice Public Park, and from such a beautiful district other good kinds should be forthcoming. I believe

MME. VERNOREL is also from the same raiser. It is just that fine deep, full flower so dear to the heart of the exhibitor, and it has the yellowish colour of Jean Ducher, with a shading of rose. The growth is strong, and we have in this variety a first-rate novelty.

DR. F. GUYON seems to be a near relative, perhaps from the same seed-pod as the last-mentioned, but yet sufficiently distinct to be worth growing.

BEN CANT.—The rich, glowing colour and grand form of this, together with a vigorous growth, are all points that go to the making of a good pot-Rose.

LADY ROBERTS comes of a good stock. It is reputedly a sport of Anna Ollivier, and all who have grown pot-Roses know what a fine kind the latter is under glass. It is only recently the sporting habit of Anna Ollivier has been noticed, although many Rose growers believe

stock. It is worthy of note how some amateurs succeed when they have a love for gardening.—J. CROOK.

Rose Crimson Rambler in bloom.—It may interest your readers to know that I have a Crimson Rambler now in bloom. It is an old plant, and grows on a rustic wooden pergola running north and south. I shall be glad to know if it is not very unusual for this Rose to bloom a second time, and so late in the season? It has never done so in the five years I have been here. Several of our Chinas, Teas, and Hybrid Perpetuals are still blossoming, although the blooms are small and almost scentless. The following is a list of those Roses now in bloom: Viscountess Folkestone, Iffrace Vernet, Mfrquis of Salisbury, Caroline Testout, General Schablikine, Perle d'Or, Louis Philippe, Sanguinea, Mrs. Bosanquet, La Vesuve, Ulrich Brunner, Souvenir de Malmaison, Mme. Eugene Resal, Laurette Messimy, and Irene Watt.—C. M. B. WILKIE, *Tatham's, near Godalming.*

CHRYSANTHEMUMS.

BLOOMS EXHIBITED AT THE N.C.S. NOVEMBER SHOW.

The following figures, which relate to the number of blooms exhibited in the classes at the great show of the National Chrysanthemum Society in November last, will no doubt prove of considerable interest to readers of GARDENING ILLUSTRATED. A bunch of Pompons or singles is counted as one bloom. Blooms exhibited in—

	1902	1901	1901
Japanese	1797	2445	2112
Incurved	471	657	543
Reflexed	21	48	30
Large Anemones	108	152	211
Anemone Pompons	12	18	24
Pompons	114	54	108
Singles	18	24	24
Total	2514	3378	3300

From the figures given above it will be seen there was a great falling off in the total number of blooms exhibited on the last occasion as compared with other years. This does not necessarily mean that the Chrysanthemum has lost its hold upon the flower-loving public. The methods of exhibiting the blooms are changing, fortunately, for the better. The best of the large blooms are now exhibited in vases, instead of on the flat and uninteresting green-painted boards, which only a year or two ago were considered the only proper and orthodox way of displaying the beauty and charm of these large blooms. Blooms, when set up in vases, make a far more attractive display than when they are arranged on the boards. When arranged in vases, the space occupied by the exhibits is far larger, consequently, so many blooms are not required to make a really fine display. The falling off in the Japanese and incurved sections may be attributed chiefly to the lateness of the flowering season. Many growers could not get their blooms finished sufficiently early for the chief metropolitan fixture, and for this reason the competition was less severe than usual. By a reference to the reflexed section in the table of figures, it will be seen how they are declining in popularity. Poor as was the display of this type of the flower in 1900, when only sixty blooms were exhibited, the display on the last occasion was limited to twenty-four blooms—two boards of a dozen blooms in each. At their best these reflexed blooms are very formal. The quaint blossoms of the large Anemones and Japanese Anemones also show a considerable falling off, as compared with the exhibition held in 1900. A drop from 204 to 108 in two years is a serious matter, and points to some lack of interest by the executive, or to the want of more liberal prizes, to tempt growers to cultivate and exhibit them. The Anemone Chrysanthemums, to my mind, are among the most interesting of the many types of the Autumn Queen. Not only are the blooms quaint and curious in their form, but they are so elegant in their build and so useful for decoration that the N.C.S. might well give more encouragement to these sections. More classes should be provided, and also more liberal prizes offered, and, if it is necessary, the number of classes devoted to Japan-

nese might very well be reduced in order to effect this. The undue attention given to the Japanese section is ousting these pretty flowers from the exhibitions, and this cannot be disputed in face of the fact that 108 blooms represented both the large-flowered Anemones and Japanese Anemones at the great exhibition of the National Chrysanthemum Society in November last. The same remarks apply with equal force to the Anemone Pompons. These beautiful free-flowering Chrysanthemums were represented by twelve small bunches on the last occasion, against double this number in 1900. This is a matter for regret, and interest in these lovely flowers should be stimulated by providing more classes and offering liberal prizes. The Pompons appear to be holding their own fairly well, but 114 bunches are, after all, a meagre display. Much cannot be said for the singles, as November is really too early to see them in goodly numbers and at their best. The rigidly disbudded blooms which are usually exhibited are made to look so formal, and the machine-like regularity of their setting up detracts from their beauty.

Those responsible for the schedule of the National Chrysanthemum Society have much to learn. All who are interested in further popularising the Chrysanthemum look to the National Society to set an example to other Chrysanthemum societies throughout the country. With the new move, which is now inevitable, the N.C.S. might well begin a new era of usefulness. The antiquated ideas which have characterised its movements all too long will have to give way to newer ideas, and the more enlightened and up-to-date methods of exhibiting, in which, of course, all sections of the flower should have due consideration, and the display, in consequence, be thoroughly representative, should be the rule. The society has now a splendid opportunity for making a clean sweep of—and ridding itself of—out-of-date and antiquated methods of exhibiting Chrysanthemums of all types and of all sizes.

A. R.

CHRYSANTHEMUMS IN VASES AND BASKETS.

MUCH as the introduction of the vase into competitions at shows was hailed with satisfaction as a welcome change from the hard lines seen in long ranges of show boxes, yet it is now found that nohow, apparently, can big rotund mop-like blossoms be made to look, however set up, pleasing or beautiful. The inherent objection lies more in the size of the flowers than in the setting up or the pile of vase or basket employed for the purpose. A singular contrast, so far as elegance, grace, and beauty are concerned, to these big show blooms, however arranged, was seen in the charming basket of Chrysanthemums set up by Miss Easterbrook, Fawkham, Kent, at the last meeting of the Royal Horticultural Society. Here quite medium-sized double with beautiful pure white singles, and some of the thread petalled varieties mixed with pleasing foliage made up in the basket a truly charming arrangement that was well worth an illustration, if but to show how to do things similarly. No vase or basket of big fat blooms could possibly look so beautiful as this basket did. No doubt, because of the prevailing craze for large blooms as seen at shows, Chrysanthemum growers have got to regard these big flowers as beautiful, whilst smaller ones get very little recognition. It is, if so, a grave mistake. Medium-sized Japanese, pretty Pompons, Anemone Pompons, and singles make up when tastefully used graceful combinations that far excel any that fat flowers can produce. A crusade against big blooms seems to be inevitable as taste becomes more refined.

A. D.

[The arrangement above referred to was one of the most dainty we have ever seen, the flowers being lightly and tastefully set up, and without that heavy, lumpy effect which is inevitable when the big fat blooms are shown in vases. The basket shown at the Royal Horticultural Society was filled with fine white single Chrysanthemums, associated with the thread petalled white blooms of the Mrs. Filkins type and Fern fronds, a light and elegant effect being in this way secured.—Ed.] Original flowers.—Essex.

NOTES AND REPLIES.

Single Chrysanthemums.—Could you kindly give me the names of some good single Chrysanthemums, and if any grower makes a speciality of them? I have one, and it has stood frost, rain, and wind out-of-doors so well, I am anxious to get a variety of colour.—C. G. (BRUX, *Poyne*).

[Mary Anderson, white, changing to blush, is probably the best known of all, and its tawny yellow sport, Miss A. Holden, is also good. Miss Chrissie, bright terra-cotta, is brilliant while the flowers are young. Buttercup bears many-flowered erect sprays of rather small round blooms, butter-yellow in colour. Emily Wells is one of the very best, with bright rose, medium-sized flowers that stand erect on long sprays. Prolific is rather large. The flowers, which open bluish-coloured, mottled with white, soon change to a paler hue, and are then very much like those of Mary Anderson in form and colour, but larger. This is a very free variety. Snowdrift is a useful white variety. For those who like very dark crimson Annie Tweed will prove a charming variety, very much like Mary Anderson in habit, form, and size. Useful late varieties are Admiral T. Symonds and Kate Williams, both large-flowered yellows. Mrs. A. E. Stubbs, creamy-white, of good form, with fairly long, narrow-pointed petals; Framfield Beauty, rich crimson; Jane, white; Yellow Jane; and Purity, white, are also good.]

Large Chrysanthemums.—Mr. C. J. Grist (page 535), very correctly defines the feelings of many lovers of beautiful flowers in his remarks concerning the monotony of the big blooms at the Aquarium and other autumnal shows of this popular flower. There is not the slightest doubt that the financial crisis to which he refers will become much more acute, unless steps are taken to introduce more variety, for the simple reason that when you have seen one show of these monster blooms you have seen them all, for they vary so little as to become wearisome. There is no doubt that big blooms, cut with long stalks and foliage, set in vase, take the eye of the visitors much more than the flat boxes, and when we turn to the groups we find the big bloom plants far less effective than the naturally-grown and not disbudded ones. The majority of provincial shows find a difficulty in keeping up the interest in these shows, and have to add classes for miscellaneous groups of plantable plants, winter-flowering Geraniums, Cyclamens, Primulas, etc., and not the least effective aid is given by the Begonias of the Gloire de Lorraine type as pot plants.—J. G. (Gosport).

Old Chrysanthemums (Miscellaneous).—If you have room in a cold-frame or greenhouse, do not be in too great a hurry to throw old stools of Chrysanthemums away, even if you have taken what cuttings you want—accidents will happen. Old plants will winter in a cold-frame if covered up on frosty nights. Where decorative Chrysanthemums are grown, often these old plants turn out the best, and bloom earlier than those from cuttings, and should be planted out in the borders in April. Stirring the soil about the roots and introducing a little fresh will induce many that are backward to send up suckers, but such treatment should be the general rule.—W. BARTWICK.

Chrysanthemums at the Aquarium.—In reference to Chrysanthemums at the Aquarium, I fail to understand how people who attend exhibitions can expect to see a lot of small blooms, instead of the magnificent specimens grown under skilful and scientific treatment. Exhibitions are not markets for cut flowers, but are held to improve floriculture and to test the skill of the gardener. There is no skill displayed in producing small flowers. What has made our Autumn Queen so popular, and what has caused it to make so much progress? Is it not the exhibitions, where the public meet to see this well-grown flower, but what some critics term "so many mops on poles"? It seems that to make any further progress is wicked. At a recent show which I attended there were classes for cut blooms and plants undisbudded, but the public took hardly any notice of them, their minds being centred on the large ones. To my mind, Covent Garden, and not the Aquarium, is the place for small flowers.—Essex.

VEGETABLES.

KITCHEN GARDEN WALKS.

Of old, the kitchen garden used to be devoted exclusively to the culture of vegetables, and in the present day more are perhaps to be found that lack flowering plants among their occupants than possess them. Now, however, that cut flowers are used so largely for indoor decoration, it is almost a necessity that some plot of ground should be set aside for the production of these flowers, for if it be not the routine drain on beds and borders will soon have an effect on the display. Unless there happens to be spare ground which may be utilised, the reserve beds are generally formed in the kitchen garden. Sometimes a small portion in one of the corners was allotted to them, and they were, in a way, kept out of sight, but by degrees the fashion of growing flowers in the kitchen garden, which first

ing flowers on either side, and arches were here and there thrown across the path on which were trained climbing Roses, Honeysuckles, Clematises, Jasmines, Vines, or other ornamental clamberers, and thus the kitchen garden assumed a fairer guise, until at the present day there be those which in interest to enthusiasts in gardening exceed the pleasure-grounds to which they are an appendage, so well-filled are the wide borders that edge the walks with all descriptions of hardy flowering plants—Lilies, Campanulas, Lupines, Swot Williams, Alstromerias, Paeonies, Poppies, Pansies, and a host of other dwarf and tall-growing subjects—while the arches are garlanded with bloom-sprays, and in the springtime the surrounding branches hold a shell-pink drift of Apple blossoms—"blossoms as tender in colouring and delicate in fragrance as the rarest exotic"—that spreads like a sun-kissed cloud above the earth. S. W. F.

waterings once or twice weekly after the blossoms are set will materially help the fruit to swell. See that the Cucumbers do not shade the Beans after they are through the soil; neither should they be more than 2 feet away from the glass roof, or the plants will be spindly and the crop unsatisfactory. Place ten or a dozen Beans in each pot, thinning down to six before crowding takes place. Some only about half fill the pots with soil at first, earthing the Beans up as growth advances, but I could never see the wisdom of this. When they have made their first true pair of leaves nip out the point of the shoot, which will cause them to branch, and before the tender stalks have a chance to bend over place supports around the edge of the pot, such as a half worn out birch broom, or three sticks 18 inches long, and tie cord around to keep them erect. The plants must be syringed once or twice daily, gently until the foliage strengthens, up to the time the flowers open, when discontinue until set, when again ply it well underneath the foliage, or red-spider will soon cripple them. As regards varieties, sow Veitch's Early Favourite, or Ne Plus Ultra and Canadian Wonder in a month's time.]

Celery failing.—I am sending you a root of Celery in the hope that in your valuable paper you will kindly give me some idea of the reason of its failure. The soil in which it was grown is light, the trenches were well manured before the planting in August, and it has been well earthed-up.—ATLAN.

[We can only conclude from the appearance of the head of Celery that you send that the seed was sown too early, that the plants remained too long in the seed bed, becoming drawn and weak. You also planted out far too late. The Celery ought to have been put out at the end of May. The plant showed the centre had run to flower, caused by its having received a check, also that in earthing up soil had been allowed to get into the heart, thus checking growth and setting up decay. Did you earth up when the soil was wet? It would have been well had you sprinkled some lime over the soil and amongst the plants ere you earthed up the Celery. The lime would have helped to considerably dry the soil.]

Cleaning weedy ground.—kindly give me your advice about some land (half an acre), which I took possession of last winter, and being weedy, Docka and Thistles reigning supreme, I had it trenched so as to get the roots out. This year I planted it with vegetables and some flowers, hoping to clean the land with the hoe during this summer, but owing to the rain and shortness of hands, the weeds again conquered, but most that are left now are shallow-rooted weeds like Groundsel, Chickweed, as I especially waged war against the deep rooters like Docka. I want to sow all the land with Grass, but I fear it is too full of seeds dropped again this year for me to venture to sow this spring as I had intended. I have been wondering if the best way of cleaning really would be to sow with Vetches as a smothering crop, as I was advised by a friend in the first instance, but whose advice I did not take. What do you think? I shall be short of labour, I know, and need to save work as much as I can. (Other advice has been to grow Potatoes and Turnips, but I would rather not have either of those crops. If you approve of the Vetches, would you tell me, (1) when I ought to sow, and (2) how much seed I should need, and (3) also how to sow—in drills or broadcast like Grass and raked in?—CROYDON.

[It is unfortunate that whilst doing so much to free your ground from deep rooting or perennial weeds, you should have allowed annual weeds to grow so abundantly. Still, the season was unfavourable to seed production, and it may be that not much of what was cast will grow. It would have been best to have sown Tares in October; now you had better wait till the weather is open in February. Even for that sowing we should not advise you to dig, fork, or plough the ground, or to stir it more than 2 inches deep. If you work it deeper you will bury the weed-seeds, and instead of being smothered by the Tares they will, when the ground is re-dug later, be brought up and will grow abundantly. A crop of Tares sown in February could hardly be got off before the end of May, and it is then rather late to break up and well pulverise the ground to sow Grass seed before hot, dry weather sets in. Probably your best course will be to give a dressing of manure shortly, to have the surface soil and manure buried down 10 inches, and you may find a clean surface soil in April to sow with Grass seeds. Vetch seed may be sown broadcast, evenly, half a pound per rod.]

Seakale.—Where the crowns are yearly lifted for forcing, no time should be lost in getting them up, reserving all thong-like roots of medium size for next season's planting,

Middle walk in kitchen garden. From a photograph sent by Mrs. A. K. Wykeham-Martin, Purdon, near Swindon.

arose from the desirability of having blossoms for cutting in some spot where their removal from the beds would remain unnoticed, has extended until many of these gardens are beautiful with blossoming things through all the seasons of the year. Long beds of Tulips, breadths of self Carnations, crimson, white, and pink, satin Lavateras, and shot-silk Salpiglossis, white Foxgloves, scarlet Gladioli, chaste Madonna Lilies, arching shoots of Solomon's Seal, Christmas Roses, and all manner of lovely flowers associate with vegetables, many of which, were they not vegetables, would be accounted of equal value in decoration as the denizens of hed and border, such as the feathery Asparagus, the twining, scarlet-blossomed French Bean, and the Globe Artichoke, with its cool grey curving leaves nobly fashioned as Acanthus, and its towering violet-blue flower-crown. By degrees, as the custom of having flowers in the kitchen garden grew, an endeavour was made to render the central walk, at all events, more presentable by grow-

NOTES AND REPLIES.

Forcing Dwarf Beans.—I intend growing Dwarf Beans in Cucumber-houses for early spring crop. Ought the Beans to be sown at once? Is Canadian Wonder the best sort to grow? My plan is to grow Beans in pots down centre of the houses as a catch crop, while Cucumbers are coming on.—T. WILKINS.

[You may sow these now at any time. We may now expect more sun, and the days will gradually get longer after the middle of the month, November, December, and January being the worst time for a supply of these to be kept up. Where the requisite heat, 60 degs. to 70 degs., can be maintained during the night, with a rise of 5 degs. to 10 degs. in the day, according to the weather, no difficulty should be experienced in getting these to fruit. Six to eight weeks will elapse before they are fit for use, and such an early crop is best grown in pots 8 inches in diameter. Light, rich soil is necessary, and the pots should be well drained, as Dwarf Beans require a plentiful supply of water after the plants are well established in the pots, and manured

making these into cuttings on wet days. Cut the larger end square across, the bottom end slanting, tie in bundles of fifty, and lay in sand or earth, out-of-doors, with 2 inches or 3 inches of soil over the top. The crowns should also be laid in the soil in a sheltered corner where they can be easily got at in case of sharp weather, a little straw litter being shaken over them in case of hard frost. A fresh supply should be introduced into a temperature of 55 degs. to 60 degs., keeping the crowns dark, so that blanching may take place. Lily White is taking the place of the older variety, being much whiter both before and after cooking.—EAST DEVON.

TREES AND SHRUBS.

SHRUBS FOR EXPOSED POSITION.

Would you oblige me by giving: 1, the names of shrubs and small trees which would grow well in a border exposed to rather strong wind? 2, The names of plants suitable for a hedge to run along a wooden fence, to grow quickly?—CLERY.

[The following will suit your requirements: *Evergreen*.—*Berberis Darwini*, 5 feet to 6 feet high, orange flowers, May; *Berberis Aquifolium*, 4 feet to 5 feet, golden yellow, February, March, and April; *Buxus sempervirens* (common Box); *Cerasus Laurocerasus rotundifolia*, one of the best and hardiest of the common Laurels; *Cotoneaster microphylla* and *C. rotundifolia*, dwarf shrubs with red berries in winter; *Ligustrum ovalifolium variegatum*, the best form of Golden-leaved Privet; *Ilex* (Holly), many varieties; *Cupressus Lawsoniana*, of which several of the dwarf forms reach a height of 3 feet to 6 feet; *Juniperus Sabina*, a pretty, spreading bush; *Osmanthus* in variety, all Holly-like shrubs, some with green and others with variegated leaves; *Taxus baccata* (common Yew), of which there are several distinct forms.

Deciduous.—*Amelanchier canadensis* (Snowy Mesplis), 10 feet to 15 feet, clouds of white flowers in May; *Berberis sinensis*, 4 feet, and *B. vulgaris*, 5 feet to 6 feet, remarkable for their autumnal display of bright red berries; *Cerasus Avium multiplex* (Double Wood Cherry), *Cerasus Padus* (Bird Cherry), and *Cerasus serrulata* (Chinese Cherry); *Colutea arborescens*, 6 feet, the yellow flowers in June, and large bladder-like pods later on, are very noticeable; *Cornus Mas*, 6 feet, little tufts of yellow flowers in February; *Cornus Spethii*, 4 feet, golden variegated leaves, *Cornus stolonifera*, 4 feet, bright red bark; *Cotoneaster horizontalis*, 2 feet, a spreading shrub, whose scarlet berries form a bright autumn feature; *Crataegus Crus-galli* (Cockspur Thorn), *Crataegus Oxyacantha* (common Hawthorn), and its several charming varieties, *Crataegus tanacetifolia* (Tansy-leaved Thorn), the latest flowering of all the Thorns; *Cytisus scoparius* (common Broom), and its varieties, 5 feet to 6 feet high, flowers in May; *Euonymus europæus* (Spindle Tree), 10 feet to 15 feet, whose drooping clusters of soft red fruits are very pretty; *Forsythia suspensa*, cut back every year this forms a bush 6 feet to 10 feet high, with golden flowers in March and April; *Genista hispanica*, *G. tinctoria* *flore-pleno*, and *G. virgata*, all members of the Broom family, from 3 feet to 5 feet high, flowering in June; *Laburnum*, one of the most delightful low-growing trees that we have; *Magnolia obovata*, 6 feet to 8 feet, purple flowers in May and June; *Philadelphus coronarius*, *P. coronarius flore-pleno*, and *P. grandiflorus*, all members of the Mock Orange family, from 6 feet to 10 feet high, with white blossoms; *Potentilla fruticosa*, yellow flowers in July; *Prunus Myrobalana* (Cherry Plum), *Prunus Pissardi* (purple-leaved Plum), and *Prunus spinosa flore-pleno* (Double-flowered Sloe) are all good; *Ptelea trifoliata*, 6 feet to 8 feet, laden with flattened seed-pods in the autumn; *Pyrus Malus floribunda*, 6 feet to 10 feet, rose-coloured blossoms in May; *Rhus Cotinus* (Venetian Samach), 5 feet to 8 feet, flowers like bunches of purplish hairs in July; *Ribes*, Flowering Currants, of different tints; *Roses* of sorts; *Spartium juncocum* (Spanish Broom), 5 feet to 8 feet, golden Pea-shaped flowers in July and August; *Spiræa arifolia*, *S. arguta*, *S. callosa*, *S. opulifolia*, and *S. prunifolia flore-pleno*, are all tree-flowering shrubs from 4 feet to 15 feet

high; *Symphoricarpos racemosus* (Snowberry), 5 feet to 6 feet, remarkable for its large white berries in autumn; *Syringa vulgaris* (Lilac), of which there are several varieties, both single and double; *Tamarix gallica* (Tamarisk), so well known as a seaside shrub, but which also grows well inland; *Viburnum Opulus* (Guelder Rose), 8 feet to 15 feet, whose snowball-like clusters of blossoms are borne in May or June; and *Weigela*s of different sorts, which are, taken altogether, a delightful class of flowering shrubs, whose blossoms vary from white to deep crimson. There are several subjects available for hedges, but some of the best are of rather slow growth. The most likely to suit you are *Thuja gigantea* or *Cupressus Lawsoniana* (both members of the Cypress family), which are quick growers, while they also retain their colour well. Both also submit readily to cutting.]

GARDEN WORK.

Conservatory.—In furnishing new conservatories one of the most important features is the wall plants and climbers. I once had charge of a conservatory where the back wall was covered with *Camellias*. The house was broad and lofty, with a span-roof. The front was nearly all glass and the back wall was 10 feet high; and against this wall the *Camellia* grew and flowered very freely, and always had a dressy appearance. An adjoining division was covered in a similar way with the Citron family, including Oranges, Limes, Shaddocks, etc. In planting *Camellias*, or any other plants, with hard wood stems, it is necessary to be careful not to bury the stems. I remember an instance that came under my notice where a new conservatory had been planted with *Camellias*, *Acacias*, and other hard-wooded plants, and it was necessary to take them all up and replant because the soil settled, and in pulling up the beds the hard-wooded stems were buried too deeply and soon began to show its effect. For covering pillars Tea Roses of the free-growing kind (Hybrid Tea) are useful for cutting. *Luculia gratissima* makes a good wall plant, and for light positions *Acacias*, *Jasmines*, *Habrothamnus elegans*, and *H. fascicularis*. *Swainsonia galegifolia alba* against a pillar is effective. One of the prettiest little twining plants for a light position against a wall or on a pillar is *Sollya heterophylla*. It has sky-blue flowers and twines very speedily round anything near. It makes a pretty specimen in a pot on a wire trainer. Years ago plant growers would occasionally include it in their collections of stove and greenhouse plants at the shows. One of the most beautiful climbers for a cool conservatory is the *Lapageria*, especially the white variety, as the flowers are so valuable for working up in a cut estate. The border and beds in the conservatory where the planting out system is adopted should be well drained and composed of the best loam obtainable, mixed with good peat and leaf-mould, and sand enough to keep it open, but care should be taken in using leaf-mould that all the bits of stick are sifted out. These fragments of wood, or even Beech Nut husks, are apt to breed fungus, which, if the border gets dry at any time, will attack the roots of the plants and prove very injurious. Fifty degs. at night is a suitable temperature now for the conservatory where plants in bloom are kept. When we have to depend largely upon forced flowers, we shall not object to a degree or two more if it can be obtained without unduly heating the pipes. Do not watering in the morning now.

Stove.—Materials for repotting various plants should be prepared in readiness for work next month. Rough fibrous peat will be required for the fine-foliaged plants, such as *Martianthes*, *Alocasias*, *Anturiums*, etc. Charcoal, loam, and clean, sharp sand will be required, also drainage materials in several sizes, for draining-pots. This forms the foundation of all good plant culture, and is especially necessary for choice things in the stove. *Anturiums*, for instance, want a porous root-run—in fact, all plants must have free drainage if they are to thrive. *Gesneras*, if well done, will be useful now, especially the *zebrina* and *cinnabarina* sections. The last-named look well in artificial light, and nice plants may be grown in 6 inch

pots. *Pandanus Veitchii* is useful, either in small pots or as specimens. The only objection to them as table plants is that the hooked spines on the edges of the leaves are apt to catch hold of anything near them.

Early Strawberries.—No time should be lost now in starting Strawberries if ripe fruit is wanted in March. They come very strongly partially plunged in a bed of fermenting leaves in a low pit. When the flowers begin to expand they can be moved to shelves near the glass, in a temperature of 55 degs., to set the fruit, a camel's-hair brush or a rabbit's-tail being used to distribute the pollen when enough fruits have been set for a crop. All remaining blossoms may be removed, and liquid-manure may be given if large fruits are required. A dozen large fruits on each plant are considered a good crop. The watering should be carefully done till the blossoms show, as, if too much is given, the leaves move at the expense of the flower-spikes. If green-fly appears on the plants they should be vaporised, and if the syringe is used on fine days red-spider will be kept down. In many places Strawberries are regarded as a catch crop, and are grown on shelves or stages under Vines and Peaches, and very good results are generally obtained in this way when the plants are well cared for. It takes a long time to produce a crop of Strawberries. The plants are usually started early in June for the first crop, and are kept moving on through the summer, rested in the autumn, and then started in a temperature between 45 degs. and 60 degs. under glass to produce fruit.

Orchard-house.—Now that the Chrysanthemums are over, the Peach and other trees in pots should be returned to the house, the loise having been previously thoroughly cleaned, and wall surfaces whitewashed. After the trees are housed the necessary pruning should be given, and the trees washed with an insecticide. Gishurst compound is a safe thing to use. In pruning, enough young wood should be left to bear a crop of fruit as near the main stem as possible, so that the trees may always keep in compact shape. This constitutes the chief art of the pruner. Anybody can use a knife, but to manage Peach and other fruit-trees in pots something else is wanted, which is best summed up in the word—judgment. A good knifeman will entirely alter the character of a tree very often without cutting much off. When a tree has been summer-pruned there is, perhaps, not much to do in winter, and yet the knife must go through the trees.

Early Grapes.—If the first crop is taken from pot-Vines, and the Vines are strong and reliable, there is not the same necessity for starting the permanent Vines very early. Still, a house of Hamburg and Sweet-water should be got ready now, and closed ready for starting. I need hardly say how important it is to start clean, and with the inside border in a thoroughly moist condition. If the roots are outside I believe in helping them with a bed of warm leaves and manure on the surface.

Window gardening.—We have had a rather sharp frost. Our thermometer registered 20 degs. of frost on December 6th, but that was the only frost that would be likely to damage anything in a dwelling-house except plants in flower and Ferns, which must have water enough for healthy growth. Other things will be better on the side of dryness for another month or so. Cactuses and Aloes may be kept quite dry for a time. This is their resting-time and excitement will be bad for them. Very few plants now will require water oftener than once a week.

Outdoor garden.—In planting shrubs nearly everybody plants too thickly. If the matter is left in the hands of a nurseryman to show some immediate effect, too many things are generally planted, and in the near future, if thinning is neglected, which it frequently is, many of the best specimens are seriously injured by overcrowding. Again, mistakes are often made in planting trees and shrubs which require a good deal of space for full development too near the house and too close to a walk or carriage road, necessitating removal or severe cutting back at

a late period. We have given up the idea of planting common shrubs as nurses among the better things. If in bleak situations shelter is desirable, plant a few Austrian Pines round the margin on the windward side. By the seaside the Canadian Poplar may be mixed with the Austrian Pines, the Poplars to be cut out when the Pines get up with a belt of this kind as a wind break. There is no necessity to plant common things as nurses among the better things, the spaces between to be filled with hardy plants and bulbs. Clumps of Daffodils, Bluebells, and Snowdrops have a charming effect among the choice shrubs and trees so long as their presence is desired, and when overgrown they could be moved elsewhere; then there is no necessity for hard defined margins to a shrubbery, unless the shrubs are to be used as a background. In many cases the effect would be better if the turf mat the growth of the shrubs, and was studded with bulbs and a few clumps of suitable hardy plants.

Fruit garden—Now that the greater part of the pruning is done, the trees, especially Plums and Cherries, which may have been attacked by insects early in the season, should be washed with an insecticide. Most gardeners have their favourite dressings for trees in winter. Petroleum in some form is a good deal used. Gishurst compound, though an old remedy, is still useful, especially for dressing trees infested with scale or American blight. Sunlight soap mixed with paraffin oil is a good cleansing agent, and, of course, fresh lime either as a wash or dusted over the trees when the branches are damp has some value in several ways, especially in its effect upon the roots when it ultimately descends into the soil. Lime is a necessity for fruit culture, especially for stone fruits. I have several times referred to the way in which the roots of fruit trees are driven down into the subsoil by planting vegetables, such as Potatoes and green crops, very near to them. This is a great evil even to trees grafted on free stocks, but it is ruinous to those trees on dwarfing stocks. Certainly nothing should be planted nearer to wall trees than 4 feet, and espaliers and bush Pears, Apples, and Plums should have a clear circle of at least 3 feet from the main stem. Some of the best Plums for planting are Victoria, Rivers' Early Prolific, Monarch, Transparent, and Oulin's Golden Gagees; Kirkes' and Gishorn for cooking and jam making.

Vegetable garden.—A stock of roots of various kinds, and roots which are likely to be wanted, should be taken up and laid in the soil in some place easily accessible during winter. Horseradish, Turnips, Salsify, and Parsnips are among the things which are generally left in the ground till frost is expected, and then have to be lifted hastily. If taken up in good time the roots of such things as Horseradish and Salsify may be laid in on a north border and a little long litter thrown over to keep the roots from drying too much. It is usual to leave Jerusalem Artichokes in the ground and cover with litter. During periods of open weather Sea-kale and Asparagus roots may be taken up and laid in ready for use as required. In the event of a long frost coming, and all things are possible, it will not be a satisfactory excuse to say the frost is so hard the roots cannot be lifted for forcing. The 20 dogs, on the night of Saturday, the 6th ult., have done some injury to Cauliflowers where exposed; but otherwise the greens have not sustained much damage. This is so far fortunate, as greens are very aspy, and would perish under a long frost even if not very severe. Fork over the Gooseberry and other fruit quarters as soon as the pruning is finished. I think it is a mistake to leave the bushes unpruned for the birds to work upon during winter, as lime, soot, and soft-soap are cheap. E. HURDAY.

THE COMING WEEK'S WORK.

Extracts from a Garden Diary.

January 5th.—With the advent of the New Year the seed catalogues are coming in and a selection has to be made. We usually get a few novelties, but our main reliance is upon the well-tried kinds, especially as regards Peas.

Chelsea Gem has been sown outside on the south border, and this and one other kind have been sown in pots to come on quickly and produce a dish or two early under glass. Peas do not force in the same way as the Kidney Bean, but they will do well in a cool, light house.

January 6th.—A range of hotbeds has been made up and covered with shallow pans for Potatoes, Horn Carrots, Radishes, and Lettuces. A few of Vnite's forcing Cauliflowers have been shifted on into 4½-inch pots, and will get a further shift into 6-inch pots when the roots have occupied all the soil. We find these come in useful in May without much forcing. We want many French Beans in March, April, and May, and every vacant spot on shelf or stage is filled with pots of Beans through the spring; then the weather becomes hot and the pots come into use.

January 7th.—In fine days the hoo is used among Onions, Spinach, Lettuces, &c. Earth has been drawn up to the Cabbages, and on the warm border, where a few rows are planted to come in early. A string of matting will be passed loosely round the largest plants shortly. A batch of Tom Thumb Savoy planted thickly in the way of Coleworts has been much appreciated. Sowed several boxes of Ailsa Craig Onions for transplanting about April. We have usually had good crops of very fine Onions from the early sowing.

January 8th.—Planted a lot of stout cuttings of Mulberry tree. We have mulched the surface with fitty manure, and they will be watered and kept moist in spring. Some of the cuttings are stout branches, and if they can be induced to root, which I think they can, they will form fruiting trees early. Camellias and Azaleas are now in flower in the conservatory, and are very bright and effective. We have still some Chrysanthemums in bloom, but the season is nearly over with them. For yellow flowers now there are Goultas and early-blooming Acacias, with early-flowering Narcissi. Sweeping, rolling, and other routine work receive regular attention.

January 9th.—Liquid manure in a weak, clear state is given to Mushroom beds in bearing. Salt is used in the water occasionally as a stimulant. Beds are covered with coarse hay, to keep the moisture and heat in the beds. Outside beds are still bearing freely. These are covered with straw and a waterproof sheet or straw mats. There is not much potting to do now, but loam has been carted in and the stock of peat and sand has been replenished. In the matter of potting soils, we find it economical to get the best stuff available.

January 10th.—Advantage has been taken of frosty weather to wheel the manure on the land which requires help, but a reserve supply is always held back for the land now under crop and for mulching purposes. Artificials are used to a limited extent to push on special crops. Mixture are often more useful than one manure used alone, but we do not intend to spend too much upon artificials. As a rule the very high priced manures do not pay to use largely, and for open-air gardening stable or yard manure will supply your needs.

Sweetening Rhubarb-wine.—During July last I made some Rhubarb-wine (6 gallons) from a recipe as here stated: "To 7 lb. of ripe fruit add 1 gallon of water, let it stand ten days. Strain off crushed fruit, and to each gallon of liquid add 2½ lb. of lump sugar. After fermentation rack it, and further add 1 lb. of sugar per gallon." All this I have done, I now propose adding about 3 ounces of salmagundi for fining purposes, so I drop off a small quantity, and on tasting I find it is much too tart. Can I again add some sugar, or what do you advise?—H. BACK.

[Your best course will be to boil 6 lb. of loaf sugar in a gallon of water; if that prove sufficient to dissolve it, then, when half cool, add the syrup to the 6 gallons of wine made. It would be sufficient to well sweeten it. Generally, in recipes the quantity of sugar advised to be used is too little, and the result is excessive tartness. The addition of the syrup should not induce secondary fermentation.]

Request to readers of "Gardening."—Readers, both amateur and in the trade, will kindly remember that we are always very glad to see interesting specimens of plants or flowers. Illustrate, if they will kindly send them to our office in as good a state as possible.

LAW AND CUSTOM.

A neighbour's hedge.—(On Sept. 20th I took a piece of 2 acres of land. The hedge on the west side of the piece belongs to the owner of the adjoining land, and has been allowed to run wild. In some places it is 10 feet wide from my side to the centre, and the customary width here is 3 feet for a ditch. I have requested the owner of the fence to cut it back, but he refuses, and he tells me I must not touch it. Can I cut it perpendicularly? If so, who must bear the expense?—A. F.

[You may cut off such part of the hedge as overhangs your land, but you must take care to cut perpendicularly from the boundary. Where the boundary is I cannot say—that must be decided locally, probably 4½ feet from the centre of the hedge, if the land is light and dry. Perhaps the line of the ditch may be still perceptible; if so, your side of the ditch is the boundary. If you cut the hedge you must bear the expense, and the severed portions must be placed at your neighbour's side of the boundary.—K. C. T.]

The right of a hedger to take the dead wood he cuts.—I engaged a man to split a hedge, and he took away some of the wood. He tells my gardener that all dead wood cut out of a fence belongs by right to the man who cuts it. Is this so, or is the man throwing dust in the eyes of my gardener? If there be such a custom, has the man the right to take the wood without my consent, the matter not having been mentioned when the contract was made?—CONSTANT READER, S.

[The property in the dead wood is in you, both before it is cut and afterwards—the hedger has no legal title to it. There is no custom bearing on the matter—that is, no general custom—but almost everywhere a hedger is allowed to take for his own use such of the dead wood he has cut out as he can carry away. But he would not be allowed to cart such away, or to sell it; and the very limited custom thus defined is not binding upon the fence-owner—he may stop the hedger taking any wood, if he chooses to do so. K. C. T.]

BIRDS.

Food for Bullfinch (H.).—Where the larger black Rape seed is given to Bullfinches it is scalded to remove its natural acidity. After scalding it should be rubbed in a dry cloth before being supplied to the bird. You need not trouble about scalding the smaller kind of Rape, which is of a purplish hue, and more generally used in bird-keeping, and known as summer Rape. This, with a little Canary seed added, together with a few grains of Hemp seed, will prove a good diet for your bird, while a stalk of ripe Plantain seed, a few Privet berries, or a piece of Apple from time to time, will tend to keep it in good health.—S. S. G.

The Wheatear (Saxicola oenanthe).—This handsome bird in confinement will continue in song the greater part of the year. It is one of our earliest visitors, generally making its appearance towards the end of March, frequenting moors, downs, commons, and fallow lands, building its nest on the ground, often under stones in old quarries. The nest is composed of Moss and dry vegetable fibre, and lined with hair or wool; the eggs are usually five in number, of a pale blue. The plumage of the Wheatear is very beautiful. In the adult male the top of the head and back are of a fine grey; a white line passes from the back above the eye, succeeded by a black band, which surrounds the eye and occupies the ear-coverts. The lower part of the back and two-thirds of the tail are white, while the tip of the tail and the two middle feathers are black; chest, delicate fawn colour, fading into white; wings, black. The plumage of the female is of a duller tint. The habits of this bird much resemble those of the Stonechat, taking low, but smooth and very rapid flights from one resting place to another, and running with great alertness over the short Grass of the downs and commons which it frequents. On the approach of winter thousands of these birds collect on the downs of Sussex, previous to their departure to warmer climes; at this season (as well as on their arrival in the spring) large numbers are captured for the sake of their flesh, which is considered very delicate. The food of the Wheatear consists of insects, especially of the beetle tribe, larvae, etc., which in their captive state should be supplied to these birds, although the general diet may consist of raw lean meat, finely minced, with a little Rice, Peas, and plain Biscuit.—S. S. G.

CORRESPONDENCE.

Questions.—Queries and answers are inserted in GARDENING free of charge if correspondents follow these rules: All communications should be clearly and concisely written on one side of the paper only, and addressed to the EDITOR OF GARDENING, 17, Furnival-street, Holborn, London, E.C. Letters on business should be sent to the PUBLISHER. The name and address of the sender are required in addition to any designation he may desire to be used in the paper. When more than one query is sent, each should be on a separate piece of paper, and not more than three queries should be sent at a time. Correspondents should bear in mind that, as GARDENING has to be sent to press some time in advance of date, queries cannot always be replied to in the issue immediately following the receipt of their communication. We do not reply to queries by post.

Naming fruit.—Readers who desire our help in naming fruit should bear in mind that several specimens in different stages of colour and size of the same kind greatly assist in the determination. We have received from several correspondents single specimens of fruits for naming, these in many cases being unripe and otherwise poor. The difference between varieties of fruits are, in many cases, so trifling that it is necessary that three specimens of each kind should be sent. We can undertake to name only four varieties at a time, and those only when the above directions are observed.

PLANTS AND FLOWERS.

Plant leaves going brown at the tips (J. S.).—Too cold water, also overhead watering at this season, would have the effect of turning leaves as those sent. You do not mention what heat you keep up, but if you have no artificial heat, you have either watered too freely or given too much ventilation.

Cypripedium spectabile (A.).—This can be grown in a pot, but a sunny window would be the worst possible position for it. This terrestrial Orchid requires a moist, shady situation, and the air atmosphere of a sunny window would be fatal to its successful culture. Specimens that are flowered in pots are grown in cold-frames and in the open where moisture and shade can be readily supplied.

Cissus discolor (W.).—If you cut the plant back in spring it will break away freely. The trimmings might be made into cuttings, and if inserted in sandy soil and placed in a close case they emit roots in about a fortnight. The plant grows well in ordinary soil so long as it is watered and the pots well-drained. During winter the plant should be kept on the dry side.

Streptocarpus (J.).—These do very well in an ordinary greenhouse temperature during winter, and enjoy a moist bottom without too wet a compost and overhead watering. Keep these thus until the end of February, or early in March if very cold and dull; then repot into a compost of peat, turfy loam, and leaf-soil, in equal proportions, with a dash of sharp sand added. Do not verpoot, and take great care not to injure the foliage. From this stage they do well to a temperature of 55 degs. to 60 degs., but will thrive in one of 5 degs to 10 degs. less.

Treatment of Lilies and other bulbs (C.).—Pot the Lilies at once in well-drained pots in a compost of sandy loam, rotten manure, and a little peat, if convenient. Bury the bulbs about 2 inches below the soil, and place the pots in a cool greenhouse, or frame. Do not water until growth commences, unless the soil gets very dry. If the pots are not filled more than three-parts full of soil (when potting), you can fill up with good, rich material when the pots are full of roots.

Abutilon insignis (A. T.).—This, also known as Abutilon lignum, is one of the best of winter-flowering plants, and does well trained up the rafters of a warm and light greenhouse. Its bell-shaped flowers, which are of a rich red colour, veined with velvety maroon markings, hang down in a graceful manner. Its blooms and buds stand out free from the foliage, a quality in which other species of Abutilon are deficient. It will grow well in any good sandy soil, and a little weak manure-water or clear foot-water, applied when the plant is in full bloom, is of great assistance.

Ixias in pots (A. E.).—These may be well grown in pots. Plant them firmly at once—six bulbs in a 5-inch pot—to a compost of sandy loam and leaf-mould. Place the pots in a cold-frame or on a shelf in a cold part of the greenhouse. Keep the soil rather dry at first, but give water more freely when the plants are in full growth. In April most of the varieties will flower, and will be very useful, as they are quite different in appearance from most plants in bloom at that season. When they have done flowering gradually dry them off, and allow them to rest till autumn, when they should be repotted as before.

Marvel of Peru (Alrebillia Jalapa) (E.).—This plant makes a well-shaped bush, and no situation is too hot and dry for it to grow in. Sow the seed in March in heat or out-of-doors in May, and the plants will bloom the same summer. The old bulbs must be taken up when the stems die down at the approach of winter, and be stored in a cellar or other dry place safe from frost. Old plants that flowered early will frequently be found to have seedlings spring up around them in the autumn, and if these are carefully taken up and stored away in a little soil they will make good plants for next year. Although they stand drought so well, yet, like all other plants, the Marvel of Peru will succeed better if planted in rich soil, and kept fairly moist.

Watering Ferns (F. M.).—Twice a week, or possibly less frequently, will be often enough to water Maiden-hair Ferns. Apply the water over the soil till it runs through to the bottom of the pot. Do not wet the fronds now. Water of the same temperature as the room is best. They must be kept in a room where the frost will not enter. If the fronds are withering away much less water should be given. Probably the soil has become close and sour; if so, withhold water for several weeks, hot do not allow the soil to get quite dust-dry. When the plants have rested for a time new growth will shoot up; then cut the old fronds away and shake up and repot in fresh porous soil containing plenty of sand in clean, well-drained pots. The roots should be done in March.

Roses for greenhouse (W. N.).—W. Alceo Richardson Rose is a grand orange-coloured variety for the greenhouse; Marshal Niel in still unobscured for a deep yellow, and Reine Marie Henriette is a good deep crimson. We would prefer Clematis Indivisa lobata in the other corner. This is a pretty white, starlike blossom, a good climber, and very profuse bloomer.

Brompton Stocks (M.).—To have these fine biennial Stocks at their best, seed should be sown out-of-doors in the month of May. When the plants are strong they may be transplanted to where wanted to bloom, but unless your position is a warm one, it is wise to plant either under the shelter of shrubs, or of a house, wall, or fence. These Stocks, though reputedly hardy, yet oftentimes are killed by severe frosts, especially if the plants have grown very strong. We have, in years past, found it to be a good plan after pulling out the strongest plants from the seed-bed, to later pot up many of the rest into large sashes. Get them well rooted, then shift them into 6-inch or 7-inch pots, and in that way keep them in a cool greenhouse or frame for the winter, planting out early in April.

Acacia armata (F. W. Cooper).—There seems to us some doubt regarding your Acacia, for you say the plant is from the open ground, whereas Acacia armata is essentially an evergreen greenhouse shrub or small tree, native of Australia. It conforms well to culture in pots, and near little bushes in pots from 6 inches to 8 inches in diameter, are grown in quantity by those who make a speciality of flowering plants for Covent Garden Market. Their period of blooming is during the months of April and May, consequently, it is true to name, your plant must on no account be pruned now, as every shoot taken off will lessen the production of flowers—indeed, to its culture no pruning is needed, except to shorten back any shoots that show a tendency to grow out of shape, and this must be done directly the flowering season is past. The treatment needed for this Acacia in a good light position in the greenhouse, and water when necessary. Throughout the summer it may be stood or plunged out-of-doors. If potting is necessary this should be done as soon after flowering as possible, but at the same time it should be borne in mind that a plant will keep in health for two or three years without being repotted.

Flower border (T. Cunningham).—There is nothing materially wrong in your suggested plan, so far as it goes. Its weak point is the little bloom that would be forthcoming. There are many other things that would do quite well and give but little trouble in keeping them in order. For example, in addition to the Snowdrops and Bluebells, you could, of bulbous things, plant such as Muscari, Primula Heliosis in variety, F. imperialis, also Narcissus poeticus plenus, N. pinnatus, N. incomparabilis Cynosure, N. L. Stella, N. pinnatifidus, N. Hornfeldi, N. Sir Watkin, etc., with Tritelesis, Anemone hortensis, A. apionica, Chionodoxa L. nobile, Dog's-tooth Violets, and others. Of plants not bulbous rooted, Lenten Roses, Christmas Roses, Hepaticas would do well. These last are not suited, however, to your plan of sowing Grass-seed, and we think a more effective way would be to carpet the border with flowering plants, such as Tuffet Vanities in variety, Saxifraga Wallacei, S. granulata plena, and others. The Oxifraga is a pretty flowering shrub and dwarf growing, and for this reason we think a good Holly like Hodgkiss or Golden Queen would be better, in your opinion, than any other idea. If you are still in doubt, write again giving some more of the things you were thinking of planting in front. In any case, the Lilies would be better than the Oxifraga, even though you adopt your plan of sowing Grass, then by adding some of the bulbs mentioned, a pretty effect will be secured.

TREES AND SHRUBS.

Common Barberry (Berberis vulgaris) (E.).—This is a British deciduous shrub, growing to a height of 8 feet or 10 feet, and bearing clusters of bright scarlet rhombic berries. It forms a noble object on the margins of scrubberies, or planted in groups on sloping banks and other conspicuous positions. Young plants are best, as old ones are apt to become "leggy" and unsightly. This Barberry will grow in any moist garden soil.

Berried Aucubas for windows (S.).—Yes, small, compact plants of the various forms of Aucuba, when well furnished with berries, are much valued in London during winter for window decoration. The way in which they are chiefly obtained is by fertilising, when in flower, old-established plants with male pollen, and then layering in light, sandy soil, good-sized branches with bushy heads being selected for the purpose and pegged down. In a short time they strike root, when they are severed from the old plant, and in autumn are lifted, potted, and placed indoors to colour their berries. Standard plants are obtained by grafting on the common Aucuba.

Dentaria gracilis (F. W. Cooper).—The old flower shoots ought to be cut down as soon as their beauty is past, just how far depending on the young growths which should be breaking away from the base of the plant. You ought to keep your plants for a month in a cold-frame, watering as the plants require, after which introduce to the greenhouse, and as the bloom-buds appear to a warmer place. On no account give the plants a warmer place than the greenhouse till the flower-buds appear, as freshly-potted plants thus early forced have a tendency to go blind, hence the need for well-established plants and ripened growth.

Shrubs for town garden (Myrrhis).—We think the Acaea or Rhododendron would succeed for some considerable time, particularly if you liberally treated the soil with good leaf-mould. Peat is not absolutely essential. These plants are frequently grown where no peat exists. Indeed, we remember some of the gardeners that formerly abounded on the Clapham High-road had many plants in the ordinary border, and these were quite a success. We therefore give you names of six kinds, various colours:—Atrorubiginum, intense blood-red, and very hardy; album grandiflorum, bluish-white, fine stems; The Queen, fine white; Mrs. R. S. Holtord, crimson-red; roseum elegans, Hendersoni, dark purplish-rose. If you try Azaleas, your better plan will be to ask your nurseryman for strong plants of Azalea mollis, either seedlings or named kinds. These are not evergreen, however. Some other good shrubs are:—Osmanthus ilicifolius, Syran-

ges paniculata grandiflora, Forsythia suspensa, Eranthis, Berberis Darwinii, B. Thunbergii, Lilac, "Gauldie" Rose, "Philadelphia grandiflora," Weigela, etc. These with asterisks are deciduous. If you wish strictly to evergreens, you are confined to Hollies, Laurels, Aucubas, and the like. Some of the flowering deciduous shrubs are very beautiful, however, and should be freely planted.

FRUIT.

Pruning (G.).—Winter pruning of fruit-trees may be done at once, and at any time for the next two months. There is really no difference as to kinds. The leaves have fallen, the wood is ripe, and the trees, therefore, may be pruned at any time. Of course, the sooner done the quicker the soil about the trees may be worked over and as desired. Prune Currants and Gooseberries also now.

Growing a Fig-tree (J.).—We do not think you would succeed with a Fig-tree in such a structure. Can you not plant one in a warm south-west corner? You could then give all necessary winter protection by partially sheltering with a mat during severe frost. Too rich soil will produce coarse growth rather than fruit. Wait until spring, and then procure a plant in a pot, and turn this out into the open soil.

Apples spotted (l'andeevion).—The spotting on your fruit is the product of a fungus, and it would do the trees great good if you would make up a wash of soft soap, sulphur, and a little fine clay, and would either coat the trees all over with that by means of a brush, or else syringe it on to the trees thickly. If you could, and while that was damp, also smother the trees with fresh-slaked lime, you would do very much to free them from the fungus spores. Perhaps the roots have gone down into bad soil, and in that case you should open a deep, wide trench 4 feet to 5 feet from the stem of the tree, covering all downward roots and filling in with some good soil. Also remove a few inches of the top-soil over the roots, and give a dressing of well-decayed manure, covering over with some good turf loam.

VEGETABLES.

Cabbage club (S. E.).—The best admitted remedy for clubbing is, without doubt, gas-lime. That should be applied to vacant ground at once, at the rate of 2 bushels to 3 rods, if clubbing is very bad. If it be not, then put 1 bushel to 2 rods of ground. After lying on the ground from four to six weeks, dig the dressing in. Even a good dressing at the same rate of fresh lime is good also. Rather than plant any of the Cabbage tribe, plant Potatoes, Seakale, or Rhubarb, or sow Onions, Parsnips, or Beet; indeed, anything other than Cabbage. By doing so for a couple of years the club trouble may disappear. Peas or Beans also may be sown with advantage.

Seakale blanching (W.).—If you had stated how were the conditions under which you were growing seakale we could have given you a more practical reply. If yours is being grown in the form of permanent plants, then all you have to do is to cover over the crowns with fine soil or ashes, in mounds some 8 inches deep, and over those lay any long straw-matting or leaves you may have to spare. If that be done in February you should have well-blanching Seakale ready to cut during April. Where Seakale is grown annually from root-cuttings to lift in the winter, forced heads may be had blanching in warmth from Christmas onwards, and the latest left in the ground may be ridged over with soil, and the stems grown will be fit to cut if so treated in April and May.

THE YOUNG FOLKS' FESTIVAL.

with its innocent gaiety and boisterous enjoyment has come round again. Whatever perplexities Mothers have about the entertainment of their guests they have long since made up their minds about one item in the menu—Jellies. Try and tancy a children's party without Jellies. And they must be Chivers, too, or the result will not be so pleasing and satisfactory. Chivers' Jellies are absolutely pure and delicious, and are flavoured with ripe French Jellies. Your Grocer sells them in pint and quart packages in various flavours. Don't forget to provide Chivers' Lemonade for the little folk. It is so safe and refreshing. Chivers and Sons, Limited, Histon, Cambridge. First English Fruit Growers' Jam Factory.

PLANTS AND FLOWERS.

OUTDOOR PLANTS.

HERBACEOUS LOBELIAS.

The majority of growers, both amateur and professional, appear to think that it is cold and damp that cause the winter losses of herbaceous Lobelias, and I notice that "A. W." writes on page 533: "Except in a few favoured districts these Lobelias will not survive our winters out-of-doors." Now the habitat of the Lobelia cardinalis is in swampy ground on the verges of North American woods, where it experiences degrees of cold and moisture greater than it is ever likely to meet with under the cultural conditions it usually enjoys in the British Isles. My experience of the plant is that it succeeds better in heavy, damp soil near water than in light, porous compost. When I had where the latter conditions prevailed and where the coldest winter frost rarely exceeded 10 degs., I invariably lost almost all the plants of herbaceous Lobelias which were left undisturbed in the open bed. Later I moved to another locality where the Lobelias were planted in heavy loam, inclining to clay, close to water. Here they withstood 23 degs. of frost unharmed, although totally unprotected, and not a single plant was lost in the severe weather which marked the opening months of 1895, when for many weeks the ground was frozen hard. In the coldest part of Suffolk, which, as anyone who knows that county will admit, is very cold indeed, these Lobelias came through the bitter winter of 1891-93, already included, to absolutely unharmed without the least protection, so that some other reasons than cold and damp must be sought to account for their failing to survive the winter in this country. My own experience points to light soil, either of a shaly or sandy nature, being the cause of their failure, and where such soil is present I should advise the importation of a barrow-load or two of clayey loam, and the planting of the Lobelias in that.

S. W. F.

PLANTS FOR BEDDING.

(REPLY TO "D.")

The only way to improve the central bed would be to discard the Pelargonium Henry Jacoby as a centre item, and in its stead employ tuberous Begonias of a crimson or scarlet shade. I suggest this as you have two Pelargoniums together. If you adopt this view, we think it will materially improve matters. In such case you would require to keep the Silver-leaved Pelargonium (Geranium) as small-growing and compact as possible. Tuberous Begonias may be had in many shades of colour, and for bedding the best way is to start them in pots and plant out in the first week of June. They are wintered quite easily in sand, and should be placed in some frost-proof building. It is unfortunate you have not given the size of any of the beds, but the Begonias may be put out about 8 inches apart—i.e., from stem to stem.

For the side beds the Echeveria would do as margin quite well, and the Pyrethrum could follow, although the latter is rather commonplace. You may keep it small by pinching. The red-leaved plant you wish for is *Alternanthera paronychioides* var. *rubra*. It is a tender plant, and you may not safely bed it out before June. You may get the plants as early as possible, and grow them on freely till that time. The "stiff kind of Moss with yellow flowers" is probably the yellow flowered Stonecrop (*Sedum acre*). Your arrangement for back border will do quite well, and if you could add a few Fuchsias and Tuberous Begonias here and there you would much improve the flowering, besides adding variety. The Begonias continue flowering to the end of October, or, indeed, until frost appears. We think you are leaving the sowing of the *Cerastium* rather late, and the end of January would be better. This, however, depends upon the convenience you have for raising such things quickly. A few clumps secured now would, in experienced hands, produce a large number of plants before the bedding-out season came round. As you are interested in carpet bedding, we would advise you to get a few plants of some of the following, and increase them for another year for the work you have in view: *Antennaria candida*, white-leaved, about 1 inch high; *Saxifraga hypnoides olegans*, dark green, dense, Moss-like, 3 inches high; *Herniaria glabra*, dark green, 1 inch high; *Sedum glaucum*, glaucous blue colour, more effective than in Echeveria, the plant of a dense Moss-like carpet growth. These are not only all perfectly hardy, but easy to increase: in fact, every fragment will grow, and you would see at once what position each was suited for. The plants named are very cheap, and are frequently advertised in our columns by hardy plant growers. The Golden Thyme is also at times employed for this work, and, like the others named, is used for its foliage only.

INCREASING TREE-PEONIES.

I will be much obliged if you can tell me the best way to propagate Tree-Peonies? I have two fine bushes on my lawn. Can I raise others from cuttings?—H. M. T.

[Tree-Peonies may be increased either by cuttings, seeds, division, layering, or grafting, this last being the method usually employed, for plants raised in this way make more satisfactory progress during the earlier stages than those increased by the other methods. In grafting, the stock employed is usually a stout, fleshy root of one of the herbaceous kinds, and the scion a young growing shoot of the current season. The best time of the year for grafting Tree-Peonies is during the month of August, when all that is required is to take a tuber having on it as many fibrous roots as possible, and having fashioned the scion in the form of a wedge, the upper part of the fleshy root must be split for a certain distance, and the wedge-shaped base of the scion inserted therein. It must then be tied securely in position, and the point of union covered with grafting wax or clay in order to render all air-tight. Of course, in inserting the graft in position care should be taken that the

bark of both stock and scion fits perfectly, and should there be any great difference between the two in size, the wedge-shaped portion of the scion may be so fashioned that an exact union is effected only on one side. After grafting, the plants must be potted sufficiently deep in the soil to completely cover the point of union, and then they must be placed in a frame which is kept close and shaded till a union is complete; but during that interval especial care must be taken not to overwater them. The most suitable scions are the good, clean shoots without flowers, but, of course, when required to increase any particular variety to the fullest possible extent, the shoots that have flowered may also be employed. *P. albiflora* and any of its numerous varieties supply the best of stocks for grafting. After a union is complete plenty of air must be given, but the better way is to winter the plants in a frame, as they are then protected, not only from sharp frosts, but also from heavy rains, which in their earlier stages must be especially guarded against. Another way of increasing Tree-Peonies that may be sometimes effectually carried out is to split up the plant after the manner of a herbaceous subject; but, of course, this can only be done when the plant has been buried rather deeply in the soil, and its several divisions have each roots of their own. Layering may also be successfully carried out for the increase of these Peonies, and this is best done in the autumn, when the portion of the branch that is to be buried must be partially cut through, and a tongue formed. The branch or branches thus layered will require to be held securely in position by stout pegs, and attention should be paid during the following summer to keep the soil sufficiently moist to hasten the formation of roots. When seeds are obtainable, which is seldom the case, they should be sown in pans of sandy loam and placed in a frame, where, however, they will generally lie a good while before they germinate, and even after this they make but slow progress during their earliest stages. See also article on the Tree-Peony, in our issue of Nov. 8, p. 473.]

CHRISTMAS WREATHS AND CROSSES.

How common now is the practice of placing on the graves of deceased relatives at Christmas wreaths or crosses composed chiefly of Ivy-leaves, with small sprays of well-berried Holly fixed into these, but standing erect, most of the point-leaves being removed. Many thousands of these mementos are now made and sold, and as they remain fairly fresh and green for a month, and are cheap, are very popular. The favourite leaves are those of the common wild or wood Ivy, as at this time of the year they assume flaked and distinctly pleasing hues. They are usually gathered and tied into bunches of twelve and so disposed of to the florists. The Holly is much the best when cut in sprigs of from 9 inches to 12 inches long, then packed into crates or into light flat wicker baskets, as then every portion can be utilised, there is no waste, nor are there large, woody branches to encumber florists and be a nuisance to the customer. The Holly, when so packed,

is removed, and the trees or bushes from which cut are not mutilated but simply pruned, and soon berry again. It would be a great gain to purchasers were all Holly sent to market in that way. When laid in neatly all round the crates, baskets, or light boxes, it is surprising how much can thus be put into a small compass. Dried flowers of one of the Staticeae have been much used this year and greatly liked when some well-berried Holly or coloured Everlastings from the Cape are introduced with the silvery Statice to give colour. Somewhat novel are chaplets, really heart-shaped wreaths, made of maroon-dyed leaves, resembling in size leaves of good sturdy Laurels. These are necessarily expensive, but find admirers. Of course, the greatest demand is for Holly and Ivy wreaths. The only forms other than round wreaths are crowns and chaplets, these being the favourite designs. For funeral wreaths, etc., nothing is now more in demand than white Chrysanthemums, still plentiful and so beautiful. A. D.

THE WHITE BUSH POPPY (ROMNEYA COULTERI)

This fine Californian Poppywort has other good qualities besides that of supreme and stately beauty as an outdoor plant. Flowering as it will from May to November, when the size of the flower decreases as cold days and nights check the development of the many yet unopened buds, it may well be considered one of the best of plants for yielding a long succession of bloom. It lasts well in water, and its delicate perfume is most acceptable in a room. The texture of the petals is very delicate—indeed, half transparent; they never lose the crumpled folds that in the case of most Poppies betoken a newly-opened state. The bold centre of yellow stamens gives the utmost colour value to the dainty milk-white of the petals, with which the pale glaucous, deeply-cut leaves are in quiet harmony. The flowers are borne mainly on the points of the new shoots and on laterals near the points, more sparingly on the lower laterals.

It does best on soils such as a warm peaty sand, blooming in such from June to October. Where it will not succeed in the open it would do so in many places against a wall with a southern aspect, as in the illustration we give to-day. No one need doubt the fitness of this noble plant for English gardens.

NOTES AND REPLIES.

Mauve and yellow perennials for autumn.—I shall be most grateful for advice as to what herbaceous plants to use for a border I wish to be all mauve and yellow in autumn? What other autumn-flowering mauve perennials are there besides Michaelmas Daisies?—*Wm.*

[If you do not interpret the former colour too literally, we think you may include the Italian Starworts, Aster Amellus, A. A. Bessarabicus and its many varieties, with the Michaelmas Daisies proper. Apart from these, you will not obtain a very numerous company in this particular colour. One of the best things is Scabiosa caucasica, and, by securing strong plants, a good show should be forthcoming. Statice latifolia is excellent (2 feet), and Eryngium amethystinum (3 feet), E. planum (3 feet), E. alpinum (3 feet), and E. tripartitum, are of the stool-blue tones that would come in this set, perhaps. To these may be added Echinos-

Ritro and E. ruthenicus, both 3½ feet high, and with certain pretensions to blue. In the Bolfowers or Campanulas there is much material at varying seasons, but for autumn the best would be C. lactiflora curulea, a plant 4 foot high, and very free. A very charming thing is the new Lathyrus pubescens, an exquisite bit of colouring, but, perhaps, not too hardy. Delphinium Belladonna (2 feet) you may purchase in autumn. There are purplish and slate colours, as also intermediates of both, in the herbaceous Phloxes, but no mauve. One of the very finest of blue flowers is Veronica subsessilis, worthy of extensive cultivation. These are some of the more striking, but there are others of dwarf habit, as the Tufted Pansies, Creeping Veronicas, etc. Of yellow flowers there is plenty, and especially in the two large groups of Helianthus and Heleniums. Of the former, there are at least a dozen kinds, and half this number of the latter. All are

The white Bush Poppy (Romneya Coulteri). From a photograph by Miss T. Niblett, Upham, Ledbury.

good and showy, as well as free-flowering. Other plants are Conocopsis grandiflora, Achillea Eupatorium, Gaillardia Vivian Grey, Lupinus arboreus, Kinothera macrocarpa, G. fruticosa, Rudbeckia Golden Glow, R. californica, R. laciniata, R. Newmanii, etc., Verbascum in several kinds, and others. Quite a large number in the yellow set are vigorous in growth, and would require plenty of room. Apart from those named are the Day Lilies, but few extend to autumn among the yellow kinds; perhaps one of the latest of these to bloom is Hemerocallis Thunbergii (2 feet). Kniphofia Chloris, K. citrina, K. Lachesis, are the most yellow of the Red-hot-poker family; K. Solfaterre is also of a yellow tone. These, we think, will afford you much material to work up for the present, and all are showy and effective.]

Shading hardy plants.—There are some kinds of hardy perennials, such as Primroses, especially the double-flowered kinds, Polyanthes, Christmas Rosos, etc., that dislike hot sunshine. Young seedlings, too,

certainly grow more freely if screened from the burning sun in July and August. The difficulty I have experienced is in finding a way of giving the required shelter in an easy and inexpensive manner. If mats or canvas are used, a framework of some sort is indispensable, and the construction of this involves more labour than one can in a general way afford. The best thing I have found for this purpose is sprays of Birch. In the spring lay in a store of Birch faggots and select the twiggy parts of them. Should a period of very hot, dry weather set in, it is an easy matter to lay some of this material on anything that may need a little shade, and on the return of moist, dull weather there is no need to remove it, as sufficient light will be admitted to keep the foliage from becoming weakly. It is surprising how well many hardy things do with this slight shelter. In the case of Hellebores and the hardy Primulas it seems to be just what they need. In a very hot, dry summer one cannot give everything that needs it a constant supply of moisture at the roots, and many hardy things do not require a great amount of it if they do not get the very hot sun on them. They thrive just as well in partial shade with the soil in a semi-dry condition when in full exposure and constantly watered in a parching time. Violet culture in some places is troublesome and often unsatisfactory by reason of red-spider attacking the plants, but a little shade will do more to keep it off than a great amount of attention with the watering-pot. Young seedlings raised early in summer make much more rapid growth in the great heat of the sun is warded off.—*B.*

Low growing perennials.—Would you kindly tell me what are the best low-growing perennials for carpeting a herbaceous border? I want yellow spring blooming ones, blue and pink summer blooming, and yellow and red autumn ones. I want all the bare ground between the large clumps of perennial plants covered.

[We are in sympathy with you in your desire to carpet the ground between the clumps of bold herbaceous plants. In this way the frequently objectionable surface is hid from view, and in its stead, if well treated, a valuable ground-work of flowering plants is seen. A possible objection to this carpeting, if too rigidly observed, is that the working space is unimpaired for those things requiring periodical attention. There is, however, no reason for crumpling the surface that no room exists for necessary work. On the other hand, a carpet of plants is not only acceptable but very desirable. You ask for "yellow in spring blooming," and we believe nothing so well fills the place as the good yellow Tufted Pansies. These are to be had in several shades and planted in groups are most effective. We some years ago planted freely on this plan, and the wealth of bloom was very great. Some good kinds are: Bullion, Ardwell Gem, Lady Echo, Golden Gem, Grievet, and Lema's Queen. These may be planted at any time a good ground in open weather. Obtain well-rooted cuttings as opposed to mere divisions, and when planted and growing freely reach the point of each shoot to cause the plants to break. In this way the plants may be put out at 6 inches asunder. We think you will have to fall back upon the Tufted Pansies for the summer "blue," for we call to mind no carpeting perennial that would answer the purpose. The only plants we have in mind are Campanula muralis and C. turbinata, while we are in worse case for the summer "pink." In the late spring months the colour could have been supplied by the dwarf Phloxes, but these complete their flowering in June. For yellow in autumn we recommend Achillea aurea and A. tomentosa, very nearly allied in habit of growth, and both yellow flowered and about 5 inches high. For the red we think you will have to be content with Zauschneria californica and Z. c. splendens. Polygonum Brunonis may also be serviceable. Two of the best carpet plants in this shade are Saxifraga muscoides purpurea and S. Rhei, the blossoms being reddish-carmine and spotted red respectively. These, however, are spring flowering. What we regard as an essential to a good carpeting plant of a perennial character is one that is easily and quickly increased, and coupled with this a plant not impatient of disturbance. Many good carpeting plants are omitted by reason of the rigid colour conditions.

CHRYSANTHEMUM MAXIMUM AND ALLIED FORMS (GREAT OX-EYE DAISY).

There are now many beautiful varieties of these Perennial Marguerites, as they are frequently called, and the best kinds make a very fine display in the garden for a long period during the summer months. It is not many years since the somewhat coarse-growing *C. latifolium* was the principal kind found in lists of hardy plants, and then it was offered as *C. maximum*. Presently, however, a dwarfier and certainly a more refined and beautiful plant generally came into notice as the true

to some extent, is dependent upon circumstances, and especially in respect to the depth of the soil. In any case, however, where the finest flower-heads are required the plants should be freely broken up every two years. The best time to do this is in early September or early in March. For very light soils September is best, and the plants quickly obtain a fresh root-hold. In the more heavy and cold soils the early part of the year will answer quite well. Where a large stock of any one kind is required this is best done by means of cuttings in spring, the cuttings in the slight warmth of a dung frame rooting freely. The following are some of the best varieties in

the tips of the florets deeply cut into narrow segments. A fine pure white and very free-flowering.

C. M. G. H. SAGE.—This is also a distinct form with the deeply-notched florets of the last-named kind.

C. M. GRANDIFLORUM is one of the best of these plants, the broad florets pure white and very fine in form.

C. M. DICHESS OF ABERDEEN is a fimbriated kind, with snow-white and very handsome flowers.

C. M. EARL ROBERTS is one of the finest yet raised of these plants. In

C. M. MADRICK FREDWARD, a very large and showy kind, the flowers are very bold and telling.

C. M. JAMES CUCKER is a variety with more rounded flowers and distinct from the rest.

C. M. TRIUMPH is one of the latest, and has enormous pure white blossoms.

C. M. PRINCESS HENRY (flowers of which are represented in the illustration) is also a fine addition to the group.

All of these are forms of *C. maximum*, and distinct from these are the forms of *C. latifolium*, which flower later and continue longer into the autumn months. Two of the most notable are known as *C. l. "Top Sawyer,"* and *C. l. grandiflorum*, fine plants attaining nearly, or quite, 4 feet in height, loaded with pure white flowers. In a mass or large bed these are most effective. E. J.

CHRYSANTHEMUMS.

NOTABLE CHRYSANTHEMUMS.

In the following notes I have jotted down the names of varieties, particularly those the blooms of which appeared to me the most striking at recent exhibitions. Some of them are new, but the majority I have grown, and can therefore point out any characteristic in habit of growth. There are, I know, readers who do not admire giant flowers; still, the fact remains that most people who cultivate Chrysanthemums require flowers as big as it is possible to obtain them. Too many of the varieties (and popular ones) have little grace in form to recommend them, the petals being too short. The long-petalled ones appeal to no most, or those handsome Japanese of an incurving nature. In both of these respects the sorts named are the best, and neither are they wanting in rich or delicate colours.

PRINCESS ALICE DE MONACO.—This splendid variety has been renamed Miss Elsie Fulton, and is much admired. Bearing the last name, too, it has been certificated by the Royal Horticultural Society. This is unfair to the raiser, who loses the credit of producing such a magnificent kind. M. Nonin is the raiser, and the colour is white. It is of incurving shape, very large, and beautifully formed. Every bud opens well, and from late struck cuttings one may get it at its best on plants no more than 2 feet high. The foliage is excellent. Being the first to mention this variety—two years ago—from a comparatively poor flower I am glad it has exceeded anticipations.

MR. F. S. VALAIS.—This variety is better than G. J. Warren, hitherto considered the finest yellow for exhibition. The latter is difficult to grow, whereas the newer is easy. It is dwarf, the blooms are very large, yet of most graceful formation. It is one of M. Calvat's productions.

MADAME PAOLO RADAELLI is a grand incurving flower; colour rosy white, not at all faded, as many of such tints look. The bloom is remarkable for size and elegance, and the variety is of sturdy growth and easy to grow. The system of late-struck cuttings, each plant to carry one bloom, suits it admirably.

MADAME WALDECK ROSSIGNOL.—This is another bloom of incurving shape, and really marvellous in size. Colours deep crimson and bronze, the latter tint, of course, predominating. Such a variety, which is of easy culture, will be much esteemed when it gets more plentiful.

MISS MILDREN WARE is an English seedling of much beauty. The florets droop and are of great length; colour a distinct shade of light brick red, and very telling. Many regard this as the choicest now kind of the year.

GEORGE PENFORD.—This, too, is an English

Chrysanthemum maximum Princess Henry in Mr. Gumbleton's garden at Belgrove, Co. Cork.

C. maximum. It is, in all probability, due to a mixture of these two by cross-breeding and seedling raising that we owe not a few of the good forms that are now found in gardens. Like many other plants, however, for which in the past there has been a demand, the varieties of these Ox-eye Daisies are too much alike, and by no means all of them, or even the one half of them would be required in any one garden. These plants are very easily grown and increased. In respect to the former, the plants may be grown to perfection in any good ordinary garden soil, and if precaution is at all necessary it is that the soil should not be over-rich. A more important matter than that of excessively rich soil is frequent division—that is to say, at intervals of about two years. This,

cultivation, the flower-heads often measuring as much as 5 inches or even 6 inches across:—

C. MAXIMUM.—This is a reputed Pyrenean species and of neat habit, rarely exceeding 2 feet high when in flower. The flowers are produced on erect, slightly-branching stems, and are about 3 inches across. Of this kind there is quite a number of beautiful forms, all alike useful for the garden and for cutting. The principal varieties are:—

C. M. "MUNSTEAD VARIETY," pure white, and about 3 inches in diameter. Very good for cutting.

C. M. ELEPHANS is rather less wide in the petals or rays, and the flowers are about 3 inches across. A very graceful plant.

C. M. FILIFORME is a distinct plant, having

seedling, and, I think, a splendid gain. The colour is rich, deep crimson, reminding one of the older Wm. Seward. It is large, with drooping formation of petals, which have an elegant twist, and exhibit a little of the gold reverse. For some time the desire of raisers has been to improve the crimson sorts. This, then, is a real improvement.

DUCHESS OF SUTHERLAND was raised by Mr. Penford, who obtained the last named, and it is magnificent. The petals are of extra length, drooping and curling in the most graceful manner possible, and building up a large bloom; colour intense yellow, a deeper shade than in any I know. It is a good grower and a decided gain.

GENERAL HUTTON.—This is remarkable for size, and with that drooping shape so much esteemed. Bright bronzy-yellow will describe the tints, whilst the growth is all that can be desired. This sort does well from late-rooted cuttings, a mode of culture suitable to the amateur with limited room. It is an Australian seedling.

SIR CHARLES SEELY is another Australian seedling. I have only seen one big flower of it, but it appears to me a magnificent addition, being one of the choicest forms of the drooping habit of flower yet noted. The colour is a nice shade of purple-rose.

MAFELING HIKO.—This kind has been exhibited frequently in fine form. It is a large, spreading Japanese bloom of a deep red colour. The only fault it has is a tall habit of growth. The same fault applies to

MADAME HERKEWEGE, a white flower obtained by a shoot of Australia "sporting." The flower is grand.

MRS. G. MILEHAM, an English seedling, is quite the best pink Chrysanthemum yet introduced. In size as well as shape it is excellent. The habit of the plant, too, is dwarf.

MRS. GREENFIELD may be regarded as an improvement on Phœbus, which has been a favourite for so many years. The colour is richer, the petals have more substance, and the plant is, if anything, a better grower.

S. T. WRIGHT.—This crimson variety is one of the new sorts of the year. It is splendid in size, form, and colour, and will be much esteemed.

MRS. T. W. POCKETT has fully borne out the high opinion formed of it last year. The easiest of all Chrysanthemums to grow, it is especially adapted for amateur cultivators. A plant will produce half-a-dozen finer blooms than if restricted to three. From very late struck cuttings I have fine blooms on plants barely a foot high. Colour a light shade of yellow, and the form of the bloom drooping.

MRS. H. EMMERTON is another yellow or straw colour. This is a fine variety in every way. Large, handsome in shape, with excellent foliage, it is among the easiest of sorts to grow.

HENRY PERKINS.—This new variety is notable for its great length of petals, which, being numerous, build up a handsome flower of large size. Colour a bright deep crimson.

BESSIE GODFREY is among the most charming of all yellows, the size of the flower, and the shape, too, are remarkable; the colour being soft and refined. This has a desirable habit of growth.

ETHEL FITZROY may be described as an orange-coloured flower. It is the most distinct and best of the shade. The forets incurve slightly. A dwarf and easy grower.

GODFREY'S PRIDE.—In this flower the forets are long and spreading, but have a peculiar curl at the points which gives a distinct appearance to the flower. It is noble looking exhibited in a vase. Habit of the plant sturdy. Colour a light shade of red.

W. R. CHURCH.—This variety is now pretty well known, but is named on account of the large number of fine blooms noted. It can be overgrown, then it is coarse, but nothing in Chrysanthemums is more striking than this, when the crimson colour is just relieved by the yellow tips to the petals.

MISS ALICE BYRON is indeed a splendid white variety. It is always good. The incurving petals make up a massive flower generally admired.

MARQUIS V. VENOSTA.—This kind was noted in fine form, much better than I have seen it since

its introduction two or three years back. It is a huge drooping bloom of a purple-rose shade. Amateur growers appear to exhibit this well. Why it is some sorts do better with amateur cultivation than with others I do not know, but absolutely the brightest Chrysanthemum in the large show at the Aquarium was in a stand of one such grower. The variety was Royal Standard, a sort most of us have discarded because so uncertain. Yet, here it was almost scarlet in its intense shade. The last to note is

SIR H. KITCHENER, not because of its novelty, but a bloom of it was the largest Chrysanthemum I have seen. It measured 10 inches by 9 inches as growing on the plant. H. S.

NOTES AND REPLIES.

Single Chrysanthemums.—How beautiful these are, either as plants for room decoration or in a cut state for placing in vases; and, no matter how they may be employed, they always arrest attention and excite admiration. There have been many additions of late, but the following are still hard to heat when given good culture: Mary Anderson, Annie Holden, Irene, Eucharis, Golden Star, Miss Rose, Cannell's Perfection, Framfield Beauty, and King of Siam. In the nine varieties enumerated the colours range from pure white of Irene and Eucharis to the dark maroon of Framfield Beauty and King of Siam, Golden Star being a fine buttercup-yellow. If propagated in March fine bushy plants will result, that begin to flower in November, and follow on in succession until Christmas.—A. W.

Chrysanthemum Gladys Rout.—This is occasionally referred to, but it is very little known. The plant has been in commerce for some years, and here and there a market grower has recognised its dainty form and chaste characteristics, and has sent it to market with good results. The blooms are pure white, with long, narrow petals, and they are produced on the plant quite freely. To be seen at their best, however, the plant should be disbudded, or partially so at least. As its habit is good, and its height is about 3 feet, it deserves extended culture. In ordinary seasons from a late crown-bud selection the plant comes into flower in October, but the abnormal season through which we are now (mid-November) passing the flowers from terminal buds are only partially developed. A note should be made of this plant.—W. V. T.

Chrysanthemum novelties of recognised merit.—This season novelties have not been so numerous as usual during the flowering period, and at no time during the exhibition season has a large number of new sorts been staged for adjudication by the floral committees of the N.C.S. or R.H.S. at any one meeting. Raisers and introducers appear to understand much better than formerly what is required of them when submitting novelties for the judgment of the respective committees. Because of this fact, blooms of poor quality, and those, too, of medium size, have seldom been seen, so far, this season. For exhibition purposes, size, and this as large as possible, still appears to be the chief object desired, and however refined and pleasing in colour the novelties may be, if they lack size they are almost entirely ignored. Occasionally a bloom of medium size gains a commendation for its colour, but these instances are very rare indeed. It is curious to notice how the judgment of a committee of experts may be influenced by the order in which the blooms are submitted to them. Should a very large bloom of good form and striking colour be the first to be adjudicated upon at any one particular sitting, it invariably gains the coveted distinction of a first-class certificate, and a high standard is consequently set up. Other varieties, subsequently submitted at the same meeting, are expected to attain the same standard as the first one, and any novelty, however meritorious it may be, failing only in the merest particular, seldom receives recognition at the committee's hands. The chances are, that, had flowers of a lower standard of quality been put up in the earlier period of the same meeting, they might have been recognised with an award of some sort, although such recognition may not have been quite unanimous.—E. G.

ROSES.

LONG FLOWERING ROSES IN 1902.

SUCH an autumn for Roses as that of 1902 has seldom, I suppose, been known. All, or nearly all, have done well; but some among them undoubtedly carry off the palm for beauty and persistence in blooming. I will begin with the glorious Réve d'Or. It is barely three years old, planted late in the autumn of 1899. It now covers a space two yards each way, and its great brown shoots are running up into the fence to mingle with a vigorous Crimson Rambler, thereby promising much pleasure next year. From June to November it has been covered with hundreds of its fragrant, tan-coloured blossoms, and if they have waned for a moment, the rich foliage has always made it a delightful object; while, beyond it, Longworth Rambler, with its semi-double clear scarlet-crimson flowers, has run riot over the fence and the Furze bushes. But, surpassing even Réve d'Or in beauty, is a bush of Marie Vanhoutte on the other side of the straight path from the gate to the house. A plant of three years' growth shows sixty-two well-shaped blooms in the middle of October, with promise of as many more to follow. By an even higher place must be assigned to the more solid Madame Lambert, with some twenty noble blossoms on one brown shoot of last summer's growth, somewhat paler than the July flowers, but of astonishing size, substance, and fragrance.

So far I have not succeeded as my neighbours the cottagers do with standards—my garden is too windswept to suit them yet; but a couple standing on each side of the path are the exceptions, and match each other for shell-pink blossoms, shape, size, and persistence in blooming. They are Mrs. Sharman Crawford and Madame Caroline Testout. From late June to the third week in November they were never without a flower, and though one is a Hybrid Perpetual and the other a Hybrid Tea, there is but little to choose between them. Madame Pierre Cochet, a smaller W. A. Richardson, with excellently-shaped buds which do not change colour, and Isabella Sprunt have also lasted well in these borders. So has W. A. Richardson under the south window, where Climbing Captain Christy mingles enormous pink globes with its golden flowers, and with the copper and pink of the fragrant, old-fashioned, and now neglected Noisette Ophirie.

It is my endeavour to collect in this new garden the Roses I remember as a child at the old home a mile away. I rejoice to see signs that a taste is gradually reviving for some of the lovely parents of our gorgeous exhibition Roses of to-day. On the west wall of the house is another of these beautiful and fragrant old Roses, so seldom seen now that I hunted through a dozen catalogues before I could secure it—the Noisette Jaune Desprez, raised by M. Desprez about 1825, and which should be found in every Rose garden. It needs good food and a little protection of Bracken about the roots and lower shoots in winter; but even in my Cave of the Winds it has grown up to the eaves in less than three years, and blazing June and chill October alike have seen its sweet-scented, rosy-copper flowers hanging in large clusters from the end of every ripe branch.

The ever-flowering Grass an Toplit just beyond is a crimson Hybrid Tea, which cannot be too highly praised for colour, sweetness, handsome foliage, and abundant blossom. I find that against a wall the flowers are larger and richer than on dwarfs or standards in the open, but this may be merely accidental.

Let us now move on to the long Tea Rose border, and see which of the little plants—put out in December, 1901—are the latest and strongest bloomers. Heading the list is the delicious Mme. Abel Chatenay, with Francesa Kruger, Graco Darling, and Jean Ducher among the pale pinks and peach colours; Gustave Regis, Etoile de Lyon, Chateau des Borgeies, the superb Mme. Ravary, without doubt one of the very finest Hybrid Teas of the last three years, Coquette de Lyon, and Kaiserin Augusta Victoria among the creams and yellows; Mme. do Watteville, pale lemon

edged with pink; Gustave Nabouand, Safrano, Comtesse Eva de Starhemberg, and Mme. Chauvy among the apricots and salmon; the China pinks, fragrant and attractive, of Luciole, Mme. Jules Grolez, Belle Siebrecht, Killarney, and Amabilis a Rose, by the way, not well enough known here yet; the fiery red and copper of Baron de Hoffmann, Tillier, Dr. Rouges, and Souvenir de Cathorino Guillot; the dark reds, Le Miroir, Francois Dubrenil, M. Desir, and grand semi-double Barlou Job. With such a set of Tea Roses in

ROSE MME. ALFRED CARRIERE.

With such a wealth of Roses suited for all purposes and situations, comparative neglect will doubtless be the lot of certain kinds, as it is of this, a fine plant of which we figure to-day, from a photograph of a plant in an Irish garden. Anyone, however, who can find space for it on a wall or fence will not regret doing so, as it blooms early and late. Its pale white flesh flowers are pretty, and the scent is delicious. If one were to choose the sweetest

shoots about a foot in length for the Roses to be tied to. Connecting chains are easily arranged. If possible, plant a fast-growing summer Rose against each pillar, and, in order that the pillar shall not be entirely devoid of blossom, an autumnal bloomer of less vigour may be planted also against each pillar. For the former we suggest Crimson Rambler, Flors, Electra, Queen Alexandra, Euphrosyne, and Felicite-Perpetue; and for the latter, Aimée Vibert, Longworth Rambler, Gruss an Teplitz, Gloire des Rosomanes, Alister Stella Gray, and Pink Rover.]

Roses for smoky district.
—Could you tell me of one or two climbing and pot-roses (red, pink, and white), most likely to thrive in a greenhouse? I do not mind how common they are. The air is too smoky for outdoor roses. I suppose it is too late to plant now, but perhaps I could get them in early spring?—MAYMAN.

[Where one is obliged to consider local nuisances, such as smoke, it is much better to grow the Roses under glass, as you propose to do. The plants can be obtained at once. Those grown in pots would be the best to purchase. You can ask your nurseryman to send them out of their pots to save carriage. Good climbing kinds for such a district are—*Red*: Cheshunt Hybrid, Monsieur Desir. *Pink*: Climbing Capt. Christy, Climbing Belle Siebrecht. *White*: Purity, Mme. Alfred Carriere. For pots—*Red*: Capt. Hayward, General Jacqueminot, Ulrich Brunner. *Pink*: Caroline Testout, Mrs. W. J. Grant, La France. *White*: Boule de Neige, Merveille de Lyon, and Mme. Plantier.]

Rose Mme Alfred Carriere. From a photograph by Miss Mabel Galsford, The Grove, Dunboyne.

of Roses, this would have to be included. It is certainly the best white climbing variety we possess that has quality of blossom combined with a vigorous constitution. It is difficult to say in which class it ought to be placed, as it partakes of the rambling character of the Noisettes, but the blossoms are more like those of the true Tea-scented. Little or no pruning is necessary beyond the annual removal of worn-out shoots, together with those that are unripened, and some of the small twiggy wood in the centre of the plant.

Roses for cold greenhouse.—I have a lean-to cold greenhouse, facing south, in which I grow Tomatoes in boxes, trained to the roof. This greenhouse can be well ventilated, but is very warm in summer from the heat of the sun. I am desirous of growing Roses in slat-pots, and also three climbers in the inside border, and trained to the back wall, which is 14½ feet high. I would be obliged if you would let me know if the following varieties are suitable for the purpose, and also when I may expect them to flower if planted this or the following month? Climbers for back wall: Gruss an Teplitz, La France de '89, Climbing Perle des Jardins, or Billiard and Barré? For slat-pots: Gustave Regle, Mme. Jules Grolez, Killarney, G. Nabouand, Mme. Pernet-Ducher, Mme. Chauvy, Marquise Litta, Maman Cochet, Marquis de Salisbery, Niphotos, White Lady, and Souv. de Mathilde Guillot.—A SUGGESTION TO THE EDITOR.

[The selection of varieties you propose to grow in this unheated structure would be a very suitable one, with the following exceptions: Instead of Gruss an Teplitz, we should advise, for the back wall, Climbing Belle Siebrecht. The former, although a beautiful decorative Rose for the garden, is scarcely suitable for culture under glass. The other two for the wall would be La France de '89 and Billiard and Barré. The latter is a splendid kind, and must sooner or later be in every garden. Climbing Perle des Jardins would be much too rampant for a wall only 6 feet 6 inches high. If it is your intention to continue to grow Tomatoes upon the roof, we cannot promise you any great success with Roses, as they demand all the light one can give them. A partial shade would not matter very much during the summer months. For growing in slat-pots, of the list you submit, we can recommend Killarney, Mme. Pernet-Ducher, Marquise Litta, White Lady, Mme. Jules Grolez, Maman Cochet, Niphotos; but, instead of the other kinds, we would name Mme. Hoste, Papa Gontier, Mme. Ravary, Mme. Cadeau Ramey, and Belle Siebrecht. Plants already established in pots you would obtain in flower during April and May, but if you have specimens from the open ground, they would not give you much return until the autumn, as it is best to prune hard the first year.]

More Roses (E. A. Prescott).—Little Gem is a charming miniature Rose, with small, double crimson and well-mossed flowers; Crimson Globe, the buds well incased, and of a deep crimson shade; Laurel, with large rosy-crimson buds; Crested Moan, pale rosy-pink; Reine Blanche, with double, double, crimson; and White Bath, pure white, are all good.

October and November one may well be content.

But besides these the China Roses were in flower till the December frost came; the old common pink or blush China, beloved alike in cottage and palace, the velvet-red Craniois-Superieur, with Lauretto Messimy and Mme. Eugéno Régal, pink and red, suffused with yellow and orange; while the little Noisette Alister Stella Gray, with great clusters of flowers like a small pale W. A. Richardson, must by no means be forgotten, for it blooms late and early.—RICH G. KIMBLEY in "The Telegraph."

and want to plant four or five pillar Roses, with chains from pillar to pillar at the back. How high and of what thickness should the pillars be, and what is best to use for pillars? The front of the border is planted with H. P. Roses, edged with dwarf Polyantha Roses.—LIVAN POOL.

[It is not advisable to have the pillars too high, as they are bare for a considerable time, and appear anything but picturesque. We consider 7 feet out of the ground a suitable height for the fast-growing Roses. For stability iron standards are best, but they should have prongs or iron feet at their base to render them more stable against gales. Larch poles are very interesting, leaving the side

GARDEN PESTS AND FRIENDS.

AMERICAN BLIGHT (SCHIZONEURA LANIGERA).

Will you kindly describe in GARDENING American blight on fruit-trees?—R. B.

[This well-known pest is one of the worst foes which cultivators of Apple-trees have to contend with. When once this insect becomes established in an orchard it is very difficult, if not impossible, to completely eradicate it, and the damage it does to the trees is very considerable; at times trees have been entirely killed by these little insects, so that measures should be at once taken for their destruction as soon as any are discovered on a tree, for they spread very quickly, the eggs and quite young larvae being easily blown, with small pieces of the cottony substance with which the colony is covered, from one tree to another.

The best means of destroying this insect appears to be by scraping off the loose rough bark from the stems and branches, and removing the earth from the base of the stems and roots. Before the scraping is commenced, a sheet or cloth should be laid on the ground, so that everything which is scraped from the tree can be collected and burnt. The tree should then be well scrubbed with a hard brush and one of the following mixtures which are much recommended by various persons: Coarse petroleum oil; $\frac{1}{2}$ ammoniacal liquor to $\frac{1}{2}$ water; strong brine; soap-suds; Tobacco-water (1 lb. Tobacco to 4 gallons of water); or the trees may be painted with 1 peck quick lime, $\frac{1}{2}$ lb. flowers of sulphur, $\frac{1}{2}$ lb. of lamp-black, mixed with hot water till of the thickness of paint and used when warm; or 7 lb. of soft-soap to 1 lb. of train oil, two or three handfuls of soot and flowers of sulphur, mixed with a pailful of lime-water; then add sufficient clay until it is about as thick as butter. When the compound dries it will very probably crack; the cracks should be filled up with clay. Syringe the trees, using a fine rose, with 1 lb. of soda dissolved in a gallon of rain water and well mix with 1 pint of spirits of turpentine; then add 8 gallons of water. A small brush dipped in turpentine and brushed over the insects is a very effectual way of killing them if they have not spread much on a tree. Whichever of the above methods is used, care should be taken that the insecticide is well worked into the crevices and rough places in the bark, for it is in such places that the eggs and the young are likely to be found if this operation is not properly performed.

This insect usually selects some part of the tree where there is an inequality in the bark, and there forms a regular colony, which may be easily detected by the white cottony down with which these insects cover themselves. These white patches make the tree look as if it were covered with mildew in those parts. The insects, by constantly puncturing the bark with their probosces and drawing off the sap, bring the tree into an unhealthy condition, and cause the parts attacked to swell and form warts and knots.

The severest weather does not appear to kill the American blight. It is supposed by many that they usually pass the winter beneath the surface of the soil, feeding on the roots of the trees, and no doubt they occasionally do so, but it seems very doubtful if this be their ordinary habit. Probably what more usually takes place to insure this insect from becoming extinct is, that a few females in each colony survive the winter on the stems or branches of the trees, and commence to propagate their species as soon as the sap begins to rise in the trees, and eggs laid the previous autumn hatching about the same time, fresh specimens are produced. As before mentioned, this insect soon spreads from tree to tree when once it is introduced into an orchard, for the eggs and young larvae, attached to small pieces of the cottony substance, are easily wafted about by the wind, and some of the females are winged and able to fly from one tree to another. The American blight belongs to the same family (the Aphididae) as the common Rose aphid and the Peach aphid, and, like them, will breed for several generations without the intervention of the male. The genus *Schizoneura* contains six species. The females in the wingless state of *S. lanigera*, the species now under

consideration, are, when full grown, about one-tenth of an inch long and tolerably plump, with the joints of the body well defined. They are of a slaty or leaden black or dark brown colour, the front portion of the body sparingly covered with small short tufts of a cottony-like material, the after-part thickly covered with it, and forming a long train behind the insect of about its own length. This covering is doubtless a great protection to the insect against unfavourable weather and the attacks of parasitic insects and carnivorous grubs. The young larvae are pale yellow in colour and they gradually attain the colour of the adult insect.]

NOTES AND REPLIES.

Chrysalis in lime.—I send you some specimens of a chrysalis, which I found in large quantities in a heap of lime which was placed in a shed in my garden about six months since. If you can tell me to what insect they belong I shall be much obliged? They are something like the chrysalis of the Marguerite Daisy-fly, figured in your number of GARDENING ILLUSTRATED recently, but not quite the same.—GEOFFREY WALKER.

[The chrysalides you sent are those of a small fly belonging to the genus *Anthomyia*, as far as I can judge; but chrysalides are often so much alike, though belonging to different genera, that it is impossible to be certain as to their identity. In every case the flies had

American blight in various stages of development.

Fig. 1, Wingless Female (magnified); Figs. 2 and 3, Larvæ (magnified); Fig. 4, Apple branch with American blight (natural size).

escaped from the chrysalides. One thing puzzles me very much, which is, how they came to be amongst the lime. Were there any vegetables or plants hanging above the lime in the shed from which they could have fallen? For no larvae would have become chrysalides in the lime, and even if it were possible that they could, then would come the question: From whence came the larvae? Can you throw any light on this point?—G. S. S.]

Hart's-tongue failing.—I have a fine, well-grown Hart's-tongue Fern, which was remarkably healthy up to a week ago, since when it has sagged, and the leaves have lost their firmness, although it has received the same care and attention as before. On taking it out of its pot to examine the roots I found a number of small white, semi-transparent grubs, each about $\frac{1}{2}$ inch in length, and thin, somewhat like a small worm in shape. Can you or any of your readers tell me how to get rid of these pests without injury to the plant, and what is the cause of them? The plant was potted at the same time as a number of others, which all seem quite healthy.—DOXA, FERRIS.

[Your Fern has been attacked by the grubs of the Vine-weevil, which prey on the roots of Ferns, Cyclamens, Primulas, etc. When full grown they are about half-an-inch long, white, with brownish heads, and very much wrinkled. They cannot be reached by any insecticide so as to kill them, the best thing to do being to pick them out from amongst the roots. The weevils only feed at night, so that it is very difficult to find them. When disturbed,

they drop off the plant on which they are feeding and lie quite motionless, as if dead. You should lay a white sheet under the plant while it is still light, and about an hour or so after dark go into the house with a bright light, which will cause the weevils to fall at once. If it does not, shake the plant well so as to make them fall down.]

The Carnation-maggot.—Can you tell me the best way to prevent the attacks of the Carnation-maggot, of which I have found considerable numbers lately in the stems? In the "English Flower Garden" it says they should be searched for in the spring, while the young grub is still in the leaf, from which it reaches the stem. I should like to know a little more precisely when to look for them, and would be grateful for any other information you could give me about them.—LANSLOW.

[This is a small yellowish-white maggot, which works its way under the outer skin of the leaf until it reaches the shoot, down which it eats until it reaches the main stem of the plant, into which it bores, eating out the heart of the plant and eventually killing it. No insecticide will touch the pest, and it must be searched for and destroyed, using a pin for the purpose. The maggot should be caught, if possible, before it reaches the main stem. When there are any signs of the maggot, the plants should be gone over carefully every day.]

INDOOR PLANTS.

ECHEVERIA RETUSA.

In greenhouses where a temperature of about 50 degs. is maintained, this will bloom all in winter, and will flower on all through the spring. In cool-houses, from which frost and damp only are excluded by fire-heat, it does not commence to flower much before March, lasting in bloom up to May. It is a well-habited, showy little plant that is well worth the attention of those who like to have something bright and rather out of the ordinary way when there is not much in the shape of flowers outside. The bright orange flowers on rigid stems that spring from neat rosettes of foliage are so numerous that when in full bloom good plants make a brave show, and the colour is so distinct as to form a welcome contrast to the various shades of pink and white that frequently predominate in the conservatory in winter and spring. A large batch of plants in full bloom has a very cheerful appearance.

CULTURE.—In April the plants should be pulled to pieces. Let the soil dry out first, so when the greater portion of it can be shaken away without injury to the roots, and the plants get the benefit of a body of fresh compost. It is not, however, very important that any great quantity of old roots be retained, as, like all the members of the family, roots are thrown out all up the stem, and being of a very succulent nature, the foliage does not suffer much until these new roots are made. When repotted the stems should be covered with the new soil quite up to the leaves. Sandy loam with some sand added is the best soil, and good drainage should be given, as all plants of a succulent nature are very susceptible to stagnant moisture at the roots. Let the plants have all the sunshine and air possible through the spring and early summer, and in July put them in the open air in a sunny situation, but be careful to bring them in before the middle of September, as this *Echeveria* is rather tender, and if the points of the blooming stems are frosted but slightly, the flowers will not expand later on. A good roasting in the sun is what this little succulent requires, and then it will yield a good harvest of bloom.

I know of but one drawback to the growth of this plant, and that is the grub of the black Vine-weevil, which eats its way into the stems, and just as the flowers should be expanding the whole plant collapses. My plants were so much infested that at one time I thought I must give up its culture, but I found a way out of the difficulty that has never since failed. Instead of repotting in spring, I shake the plants out in June, and wash all the old soil from the roots, so that, if possible, not a particle of it is left. This should not be done before the latter end of the month, as by that time the weevil has deposited its eggs, and in washing the soil away the eggs or, perhaps, newly hatched grubs go with it. The crowns are then laid in in light soil in a frame in the full sun and kept watered. By the end of

July they will be growing freely, and are then taken up and potted.

WATERING.—The roots being of a fine, hair-like nature, a little more care in watering is required than with the many winter and early spring-blooming plants. Plants of a succulent nature are very impatient of much moisture at the roots in winter, and *Echeveria retusa* is no exception to that rule. Plants that are getting an intermediate temperature to bring them along may of course be watered with tolerable freedom; but where the thermometer drops to below 40 degs. water should only be given when the soil gets dry. T.

A FINE WINTER-FLOWERING PLANT (EUPHORBIA JACQUINI-EFLORA).

(REPLY TO "F. G. L.")

NEXT to the *Poinsettia*, the *Euphorbia* is one of the brightest subjects we have for this season of the year. It is rather more difficult to manage than the *Poinsettia*, as the slender roots are liable to perish if allowed to become dry or if kept too wet. It is very important to have strong cuttings, and this can only be done by looking after the old plants after the flowers have been cut. When flowering is over, the plants are somewhat shabby-looking, and on this account they are often consigned to some obscure corner and neglected. The earlier in the year cuttings can be had the better. If taken off close to the old stem with a slight heel, and inserted in pots filled with peat, leaf-mould, and plenty of sharp sand, and stood in a propagating case, they will soon form roots. I like to put the cuttings singly into small pots, as then there is no danger of the tender fibres being injured in any way. When ready for potting off, some loam and a little manure may be added to the mixture just mentioned. Early-struck plants may be stopped once or twice, but those rooted later in the season may be grown three in a pot. This *Euphorbia* must not be ripened off; the more freely the plants are grown, the longer will be the sprays of bloom. When required only for cutting it may be planted out with advantage, especially if a position where there is a little bottom-heat can be given. Give the plants plenty of drainages, using a rough, porous compost. It must be well exposed to the light, and with good treatment will stand full exposure to the sun. In the summer artificial heat is not necessary, but as soon as the nights begin to get chilly a little fire-heat must be applied. If left in a cold-house, the mischief will show itself as soon as placed in heat, when the leaves will quickly fall, thus spoiling the appearance of the plants. T.

NOTES AND REPLIES.

Calanthe Veitchi.—This most useful Orchid is not grown so much as it deserves for cutting throughout December and January. Spikes nearly 4 feet long with three dozen fully expanded blooms are no mean sight at Christmas time when flowers are so much in request. The flowers remain in good condition quite three weeks when cut if only the water is changed twice a week and the end of the stalk shortened a little. In a later issue I will give cultural details.—J. M. B.

[With the above note we received some very handsome spikes about 3 feet long, the flowers of good size and richly coloured.—Ed.]

Aspidistras.—When someone asked me to look at an *Aspidistra* that "needed potting badly," I was told, I found that the mischief did not lie in this direction, but in the fact that it had been over-watered and had become yellow. There is a danger during the winter months of window plants such as these

receiving too much moisture. The state of the atmosphere outside, as well as the temperature of the room, should govern in some measure the use of the water-pot. The potting of *Aspidistras* is best done in February or March, but this should not be until the pots are quite full of roots and really need a shift.—TOWNSMAN.

Lilies in flower.—To the uninitiated it must be a matter for surprise to see the splendid flowering examples of *Lilium longiflorum* and *L. speciosum* now so freely displayed, as their blossoms are in the usual course of events long past. This is brought about by retarding the bulbs in a temperature just below the freezing point, so that they remain dormant till long after their usual season of starting into growth, hence those in flower now would out-of-doors have bloomed in the previous summer and autumn. They need about three months from being removed from the freezing chamber and potted before the flowers expand. A few years since it would have been considered impossible to have such quantities of these Lilies in bloom at Christmas, but now the lines of demarcation between

and failing to take on that intense crimson-scarlet tint which renders them so effective for decoration. In the London market gardens they are grown in low, span-roofed houses facing east and west, with plenty of air and light in the later stages of growth, so that the wood gets firm and the leaves acquire substance. Good loam, with a liberal admixture of leaf-soil, with some manure for the last shift, is the compost usually employed. Although *Poinsettias* are in demand all through the winter, Christmas is the time when prices usually rule highest.—C., *Exh. et.*

Plants after forcing.—Though one cannot reasonably expect the plants forced in a bloom early one season to flower again the succeeding year, it naturally follows that a recuperative treatment immediately after they have flowered is essential. How frequently forced plants are neglected, instead of being carefully nursed! *Azaleas*, *Heaths*, *Epacrises*, *Genistas*, *Spiraeas*, and *Lilacs*, all valued whilst in flower, are only too often left in some out-of-the-way corner of the house, or removed to frames out-of-doors much too early, and, as a consequence, suffer from extremes of tem-

A fine winter-flowering plant (*Euphorbia jacquini-eiflora*).

the seasons are continually broken down. Regarded from a sentimental point of view, whether this is an advantage is at least questionable, though as long as it is a remunerative business it will doubtless be carried on. Lilies at Christmas are, however, not limited to these retarded bulbs, as I have a plant of the beautiful *L. sulphureum* from Upper Burmah which had two blooms expanded on Christmas morning. The bulbs were received late in the spring, potted and stood out-of-doors till the autumn, then taken into the greenhouse where the last one is now in flower. The rich ochre-yellow of the interior is, however, less pronounced than in the case of those that opened earlier. There still remains a flower, too, on *L. neilgharrense*, a much rarer Lily than was the case a few years ago. The long trumpet blossoms of this Lily are of a pleasing deep primrose tint.—W. T.

Poinsettias.—In a general way, market gardeners do these very much better than private growers. In gentlemen's gardens they are usually cultivated with other things, and frequently, from want of sufficient light and air, run up lanky, the bracts not coming to their full size,

perature. Often, too, they are neglected as to watering. Cooler conditions for plants that have been subject to a high temperature to bring them into blossom are, after flowering of course, desirable, but a generous treatment for encouragement of new wood especially is applicable to *Heaths*, *Azaleas*, and, indeed, all hard-wooded plants.—LEAHURST.

Violets in pits and frames.—During winter these are liable to damp badly, owing to the excessive moisture which settles on the foliage and flowers, therefore every endeavour should be made to keep them free of this by giving full ventilation on every favourable occasion, pulling the lights right off on fine days, and seeing that the glass is free from dirt on both sides. The plants themselves should be examined every ten days or so, removing all decayed leaves, etc., which, if left to remain long, cause spot on the leaves. Where this spot disease occurs, pick off the infested leaves and dust with a little wood-ashes and lime mixed together. The double varieties, Mrs. J. I. Astor and Lady Hume Campbell, are fine Violets for frames, and are flowering well this season, the latter being

more after the colour of the old Neapolitan, but much more robust in growth. Marie Louise is a good all-round double variety and will take a lot of beating. The White Comte de Brazza or Cannell's White appears much harder in its growth than Marie Louise, and scarcely ever shows much disease, and is most useful, especially where white flowers are in demand.—J. M. B.

FRUIT.

APPLE NEWTON WONDER.

In this we have a grand cooking Apple, large in size, of fine colour, and the tree a great bearer. It should be largely planted, as it remains sound up to midsummer in a cool fruit-room. The fruit much resembles both its parents, Blenheim and Wollington. The tree bears freely as a bush, and requires freely thinning most seasons. I also have it as an orchard standard, but the trees being small as yet, I cannot say much about it as regards this style of tree. J. M. B.

PRUNING PEARS.

Those who have not commenced this work may now do so, and persevere with it whenever the weather permits, or otherwise there will most probably be too much to do in the spring for all to be properly performed. The start should be made with Pears, and if there is not a mulching of ashes or strawy litter in front of the trees, let boards be used for standing upon, unduly trampling upon wet fruit borders having a most injurious effect. In the case of strong, well established trees, and which, say, have covered nearly or quite as much wall space as they will ever do, pruning is a very simple operation. It is these trees, however, that very often are too lightly pruned. If, owing to a too sparing use of the knife, the spurs are allowed to project 6 inches or more from the main branches, then much of the benefit that ought to be derived from the walls is lost. The fruit spurs ought to cluster round the branches and spring out not more than 3 inches from the wall, and in consequence be less liable to injury from frosts, the fruit attaining a larger size and ripening better. Trees largely furnished with long, ugly spurs ought to either have these gradually sawn off to within 1 inch of the branches, or else shortened to a back break much nearer the wall. In most instances this would be duly followed by a strong break of young shoots and fruit spurs, and which the cultivator should take good care to keep more within bounds in the future. Supposing the trees were summer pruned, spurs being left to a length of about 2 inches, the latter ought now to be further reduced to a length of 1 inch, in some instances, or where short spurs already exist in goodly numbers, to be cut quite hard back. Nothing is gained by crowding the spurs; therefore thin out where they smother each other when in leaf. If fruit-buds are scarce, leave some of the short shoots there may be with a fruit-bud at the end intact, cutting these back after the fruit has been gathered from them next season. Where there are any strong shoots available for furnishing blank space lay these in to their full length.

Pear Easter Beurre.—Late Pears are none too plentiful, and when one can say a good

word in praise of any one variety, it should prove of some service to those planters who may be undecided as to which varieties are best to plant. It thrives as a bush, but on cold soils is much better when given wall treatment, and is especially fine on the Quince as a cordon. It becomes fit for use during January, and sometimes will keep plump until March. With me it does equally well as an espalier.—J. M. B.

PLANTING VINE.

Will you be good enough to advise me what to do re Grape-Vine? It is an old Vine, been growing in the open, and this year carried 100 bunches of fruit. It has been given to me, and I have just replanted it in my own garden. I have taken four rods into my lean-to greenhouse, leaving five rods outside, trained to the wall. Would you advise me to cut off the five outside rods to strengthen the rods inside the house? I have planted for fruit, not foliage. Would half a bucket of blood benefit the Vine? May I expect any Grapes next year?—H. CLARKSON.

[We never remember having seen a Vine growing partly indoors and out, as per your illustration, and do not think it would be wise to attempt such, seeing that the Vine rods under glass, even if your house is not heated, would naturally start into growth earlier than those on the outside wall, consequently to the detriment of the latter. Therefore, it would

Apple Newton Wonder.

be better to cut off these five rods where you suggest while the weather remains mild, painting over the cut surface of each wound with painter's knotting or styptic prepared for the purpose. We do not gather from your enquiry whether you prepared your border before replanting the Vine. Such should have been done by seeing that thorough drainage was ensured, if not naturally, then otherwise, by taking out the soil 3 feet deep and about 6 feet wide, and the same in length. Then place 3 inch drain-pipes along the pit, furthest from the wall, allowing a fall of a few inches for the water to pass away at one end, which should have an outlet into a larger or main drain. Over this place 9 inches to 12 inches of broken stone or brickbats, the top 3 inches being smaller than the hulk, which will keep the soil from being washed into the drainage. Then, if obtainable, procure grassy turves about 2 inches thick and lay Grass-side downwards, when all will be ready for the soil, which, with your ordinary garden soil, would be the better if a load of the same loamy turves were chopped up and mixed together, adding 2 bushels of bone-meal, the same of soot, and two ordinary garden barrowfuls of brickbats, broken to the size of Walnuts. In planting, lay out the roots, keeping them about

5 inches from the surfaces. Do not allow the Vines to carry fruit the coming summer, but encourage all the growth you can, though not overcrowding it. If you do not care to make a new border, the blood may be put on the old border when the Vine is in active growth, say about midsummer, and let it be well washed in, after covering with a few inches of soil. It seems to us that it would have been better had you planted your Vine at the front of your house and taken the rods in through and trained them up the roof, than downwards, as per illustration.]

VEGETABLES.

MANURING TOMATO GROUND.

(REPLY TO "MARKET GARDENER.")

THE artificial manures you name—sulphate of potash one-part and superphosphate two-parts—should make an excellent dressing for ground, put on at the rate of 41 cwt. per acre for Tomatoes. These plants need relatively very little of nitrogenous manures, such as nitrate of soda, as that tends to create coarse leafage. But in manuring ground much depends on the general nature of it and the crops, as well as dressing previously given. On that head you must be the best judge. If you have grown Tomatoes in the same ground previously and they have been diseased, we fear a recurrence of the disease is probable under any circumstances. With respect to combating the Tomato fungus, there is no better fungicide than the Bordeaux or sulphate of copper mixture. Dissolve 2 lb. of sulphate of copper (bluestone) in a wooden tub containing 4 gallons of boiling water. Dissolve 2 lb. of fresh lime in a pail in 2 gallons of water. When the latter is clear pour it into the tub with the other. Then, when the bluestone is dissolved, add 16 gallon-more of water. It may be well to dissolve into it a couple of pounds of common treacle. When the liquid is quite clear it is ready for use. Give all the plants a gentle spraying or drenching with this solution. That should be done before fruits are formed. A second spraying may be given a fortnight later, and yet a third some three weeks later. If the quantity named is not enough, then make more in the same proportion. The solution is poisonous, but if not used after the fruits colour, it is not likely to do harm. Tomatoes under glass should not have too much water, nor too rich soil, and have plenty of light and air. So treated, and the soil has grown other crops previously, the plants should be healthy.

Shallots.—Will you be kind enough to tell me in OARDEENING how to treat Shallots to get them to produce and ripen seed, if it can be done in this country?—SHALLOT.

[The Shallot very seldom produces seed. The bulbs when planted in spring speedily divide into a great number of cloves, which remain attached to a common disc, and in a few months become as strong as the parent bulb.]

Horseradish unsatisfactory.—I should be obliged if any of your readers could tell me the cause of my Horseradish assuming such a unddy, dark colour, and being so tough and starchy? It was all right till two years ago. The ground was then well dug and manured, and the Horseradish replanted. It has not been manured since, but has been replanted. Any information will be gladly received, as it is in great demand.—W. P. H., *Ashton*.

[A Horseradish plantation to be satisfactory should be partially renewed every year by replanting. This should be done in a piece of well-manured and deeply dug ground, placing small pieces of roots in a slanting direction 3 feet apart and from 12 inches to 18 inches in the rows, and about 6 inches deep. The ground should be kept free from weeds, and in very dry, hot weather abundance of water, if available, may be given with advantage.]

Celeriac—This is much neglected, few using the roots for other than flavouring soups. If, however, the roots are boiled till quite tender in a little gravy, they form an excellent vegetable, the flavour being distinct and pleasing. They are also very good when boiled and served with white sauce. Celeriac is one of the best of our winter vegetables, and if the improved continental varieties were more generally grown in England they would become popular. The roots can be kept during the winter with Carrots and other roots.

GARDEN WORK.

Conservatory.—There are two families of plants which are useful in the conservatory now. One is the *Acacias*, which are showing signs of flowering; indeed, *Acacia platyptera* has been in bloom some time and *A. Drummondii* will soon follow. Others, such as *armata*, *Riceana*, *grecoidis*, *verticillata*, etc., will come in succession. *A. grandis* makes a good wall plant, and *A. Riceana* is very effective trained along a rafter or a tie rod if the house is lofty and free growth can be encouraged. The *Acacias* are very easily cultivated, either in pots or planted out in the border. If planted out the soil should not be too light or rich, as they grow so freely. Good yellow loam two-thirds, with one-third of old leaf-mould or good peat and sand, will grow *Acacias* well, either in pots or planted out. The other family to which allusion has been made is the *Bamboos*, which are very useful for backgrounds, and may take the place to some extent of the *Palms*, though, of course, the latter cannot be done without, though in a large house there is room for much variety. The early sown *Cinerarias* will now be in flower, and well grown plants are very effective. These will, of course, be grown in a low house or pit, and before they are taken to the conservatory they should be vapourised to get rid of any stray flies which may be upon the foliage, and special care should be taken that no insect-laden plants are taken to the conservatory, as it is usually much more difficult to clear them out of a lofty house than a small one, and if the conservatory is connected with the dwelling-house, great care must be exercised in using the vapouriser so that the fumes do not penetrate the house. *Camellias*, when well done, seem to supply a want now. It is comparatively easy to force into bloom plants of various things which have been prepared for the work, but a well grown *Camellia*, 6 feet or more high, either in a tub or planted in the border, requires nothing to set it off when in bloom. The reason *Camellias* have not been so much grown of late years is they are rather stiff and cannot be cut with long stalks, but anyone with a large house to fill will find a limited number of good plants very useful just now to give elevation to the house now that the *Chrysanthemums* have for the most part been moved out. Do the watering in the morning, and give a little ventilation to let the damp out. Night temperature 45 degs. to 54 degs.

Stove.—*Orchids* starting into growth will require more moisture. If on blocks or in baskets, dip them in a tank; renew the *Sphagnum* on blocks. *Stanhopeas* require very careful handling, as the flower-spikes often strike downwards and come out through the bottom of the basket. If there is a brisk bottom-heat anywhere, old plants of *Dracenas* may be cut down and the stems cut into single joints and inserted in sandy peat and plunged in heat. A very large stock may be worked up from a few old plants. Under suitable conditions, *Crotons* and *Ficus elastica* may be propagated now, but it is better to wait a few weeks if there is not plenty of bottom-heat. As the days lengthen, *Allamandas* and other plants which have been resting with the roots in a dry state may be pruned, and the roots moistened, and a little later repotted. In the meantime stocks of potting soils should be laid in an open shed ready for use when required. *Begonias* are very bright to the stove now, and early next month cuttings of the young shoots should be taken, and when established in pots some of the oldest plants of the same kinds may be got rid of. Never keep old plants of these soft-wooded things too long, as younger plants produce finer flowers, but in the case of hard-wooded plants, which are of slower growth, old plants, if in good, healthy condition, are the best. An old *Franciscosa* or *Gardenia* will produce many flowers, and should be encouraged. Use the water-pot with judgment, tapping each pot to ascertain its condition.

Early Peaches.—Do not be in a hurry. It will not pay to rush anything at this early season, and it is specially unwise to rush Peaches. Trees which have been forced in previous years will not require much rushing. Fifty degs. when the blossoms are opening will suffice; 2 degs. or 3 degs. more

in the early part of the evening will do no harm, and 2 degs. or 3 degs. less at sunrise will be the natural course. Keep the air in motion by ventilation when the sun shines, and tap the trolleys or distribute the pollen in some other way when it is dry. If the rabbit's tail or the camel's hair brush is used, pay most attention to the blossoms on the upper side of the branches, so as to get the crop as much as possible in the sunshine. Of course, when the trees are in blossom the atmosphere of the house will be kept drier and more buoyant to bring the pollen to a condition for easy distribution. Close early in the afternoon, and keep down fires in the daytime.

Early Tomatoes.—This is a good time to sow the seed of a good early kind. The seeds should be sown very thinly in boxes or pots, and placed on a shelf in a warm-house near the glass where the plants can be sturdily grown from the first. Weakly, drawn-up plants never produce the weight of fruit which the sturdy, well built-up plants do. Many growers fruit the early plants in pots, but they do us well in troughs, and it is more economical both in the materials and labour, especially in the matter of watering and top-dressing. Early Tomatoes want plenty of warmth and light. We usually grow them in span-roofed houses trained under the roof. The body of the house can then be used for bedding plants or other things coming on that may require warmth. The temperature at night may range between 55 degs. and 65 degs., which means that there will not be all that amount of fluctuation; but, say the earliest house is worked at a night temperature of 65 degs., others which are following may be 50 degs. or 60 degs. The whole matter is worked as a compromise to suit other things beside a Tomatoes. A mixture of good loam and a little old manure will suit Tomatoes at the start. What more is required can be given when the first truss of fruits is set and swelling.

Forcing Seakale and Rhubarb.—The old-fashioned way of forcing *Seakale* and *Rhubarb* under pots where the roots grew, so far as the quality of the produce was concerned, cannot be beaten where there is plenty of tree-leaves in the country, but it is a laborious method, and the modern plan of lifting the roots and forcing in the Mushroom-house or elsewhere is now commonly adopted where a good deal of produce is required.

Window gardening.—*Hyacinths* in glasses should be moved from the dark cupboard at the first signs of growth above the bulbs, and by that time the roots will have descended into the water. A little charcoal will keep the water pure. Deficiencies of the water from evaporation must be made good from time to time. *Narcissi* and other bulbs started in pots may be taken out of pots and planted in Moss in bowls at any time.

Outdoor garden.—This is the usual time, when other things are not pressing, for making alterations. I never yet knew a man or woman that was fond of their gardens that was not constantly striving after some improvement of some kind. Beautifying here and adding a fresh feature elsewhere, introducing new shrubs and trees or hardy flowers, and preparing sites for various things always give interesting work in open weather in winter. No garden is ever so perfect as a good gardener wants it to be. But, apart from this, there is always work of a routine character, which must not be delayed or neglected. Box or other edgings can be replanted or repaired, gravel walks turned over and put into shape and made firm by rolling. Tennis or other lawns can be repaired. Old worn-out shrubs or trees can be grubbed, and the site trenched and made suitable for choice trees or shrubs. If the grounds are large and of picturesque character, there is always interesting work to be done in preparing sites for new trees. *Pæonies*, both herbaceous and tree, make lovely groups in what is termed the "wilderness." Hardy Heaths and kindred subjects are very interesting in some wild spots. The *Rhododendron* family, where the soil and position are suitable, are among the most effective ornaments in the garden and wood. There are some things which are always attractive, and among these are *Rhododendrons* and

Hollies. The Birch and the Beech seem to blend well with evergreen trees and shrubs.

Fruit garden.—Those who have pruning or traiving to do should get on with it at every favourable opportunity. It is a mistake to dig with the spade over the roots of fruit trees, especially when they are grafted on surface-rooting stocks. Trees and bushes which have reached a bearing age and crop freely may have help in the way of top-dressing. It is a very easy matter to pick out those trees which require help. Of course, trees which are making wood freely do not require anything extra in the way of nourishment. There is generally something to do at this season in suppressing insect pests. The larva or eggs of flies and moths are secreted somewhere, and should be destroyed by applying the necessary remedies. I have no doubt the eggs of green-fly and root-spider are hidden away in the bark of the spurs or buds, and a wash of any simple insecticide of sufficient strength will clear off most of these if done efficiently. Insecticides are all reasonably cheap, and, if used warm, according to directions, will save a good deal of labour during the growing season. Introduce Strawberries to the forcing-houses forthrightly to keep up a succession. The flowers must be fertilised to ensure setting, and the plants should occupy a position near the glass. Early Peaches must also be fertilised individually if they flower at this early season.

Vegetable garden.—Those who have plenty of convenience for forcing will now be starting early Potatoes. The best place for them is a warm pit filled with stable manure and leaves; or an ordinary hot-bed covered with a frame, where the Potatoes as they grow can be near the glass, is very suitable. Horn Carrots sown on a bed of leaves where there is a genial warmth will soon germinate. Very often a crop of Radishes may be sown thinly among the Carrots, to be drawn out before the Carrots are large enough to thin—indeed, forced Carrots, unless sown very thickly, do not want much thinning, as by the time they are 1/2-inch in diameter the largest may be drawn out for use. There are no better Lettuces than those produced on a bed of leaves and manure under glass. Seeds sown now will come in early, especially if an early kind, such as the Paris Market Cabbage, is sown. Sow an early Pea in pots or in some other way under glass for planting out in April. A few rows may be sown outside on a sunny border in front of a forcing-house, or at the foot of a south wall. Most people have their favourite kinds. Chelsea Gem is a good dwarf kind, and a good selection of William I. is equal to most. Gradus is a good Pea, and there are many others. Asparagus, Seakale, and Mushrooms should be plentiful now, and the gardener who keeps up a good supply will have but little trouble with the cook. Salsify, Celery, and Artichokes are not difficult to produce in quantity. E. HUBBAY.

THE COMING WEEK'S WORK.

Extracts from a Garden Diary.

January 12th.—Sowed early Peas in pots and Early Longpod Beans in boxes for transplanting. Beans transplant well. Advantage is taken of mild weather to take the lights altogether off cold-frames filled with Violets, Cauliflowers, and other plants. The materials for making Mushroom-beds are being constantly collected so that exhausted beds may be cleared out and the spaces refilled. Sowed several kinds of Tomatoes for planting in early houses or growing in pots. Sowed a few Cucumber and Melon seeds.

January 13th.—Sowed Peas on early border. We always plant a few early Cabbages on a warm border to come in before the main crop. They are planted about 9 inches or 10 inches apart, and every encouragement is given for rapid growth. The Peas were dressed with red lead previous to sowing to prevent them being taken by birds or mice. A few rows of the dwarf Fan or Cluster Beans were planted at the same time. Sowed several boxes with Ailsa Craig Onions in a little warmth indoors. Looked over fruit stores. Late Peas are moved a few at a time to a warm-house to bring up the flavour.

January 14th.—Planted a lot of cuttings of bush fruits and Briers, the latter for budding. The cuttings were prepared some time ago and laid in ready for planting at a convenient season. We always like to get all cuttings selected and made early, so that the work of healing and callusing wounds may begin. All Vines in early or second early houses have been pruned, and the late houses will soon now be cleared and the remainder of the Grapes bottled.

January 15th.—Disbudded pot-Vines, leaving only those shoots which are showing good bunches: night temperatures now fall down to 65 degs. Flowers will soon be open on Hamburghs and Foster's Scedling. Orchard-house has been cleaned, and the trees in pots arranged, pruned, and washed ready for a quiet start. All inside borders of fruit-houses have been moistened where dry, and top-dressed with good loam and bone-meal. Mustard and Cress are brought on by successional sowings in boxes in heat.

January 15th.—All bushes and fruit-trees likely to be attacked by bullfinches or other birds have been dressed with a mixture of soot and lime early in the morning when damp, so that the dressing may stick. Heathitis in the conservatory are grouped at the coolest end, and are very carefully watered. Azaleas in bloom are now making a good show, and other things are coming on fast, so that all danger of a dearth of flowers has been removed. Fuchsias and other plants, from which cuttings are wanted, have been placed in heat.

January 17th.—Lily of the Valley is started in batches in a close, warm pit, kept dark at first till flower-spikes appear. If grown in pots, an inverted pot is placed over each till the flower-spikes are well on their way. Leaves are never removed from shrubberies, but are forked in, thus keeping all things in condition. Prepared a bed in a partially shaded spot for turning out the Christmas Roses now flowering in pots, when they have to be taken out. The preparation consists in deepening the soil, and working in plenty of old leaf-mould and some sand.

temperature of the house until by the time the flowers are open a minimum of 60 degs. is reached. A lower temperature even than this will suffice when the flowers are fully open. A good place to start the bulbs is in an early viney or Peach-house, transferring them when growth has well started to the stove or other hot-house.

Lawn in bad condition (A. J. Hodgkins).—Your lawn is evidently in a very poor condition, the soil being quite exhausted. The only thing you can do is to have it dug up deeply, incorporate it at the same time some good cow-manure. Do this at once and have it returned, if you can get any good turf to your district, if not, let it lie rough till April, then break it well down and add some more rotten manure, working this in with a long-toothed rake. Tread it well, level it, and then sow some good grass seed—not that from a hayloft, which is generally full of weed seeds. Protect it from birds until the seed begins to germinate.

Lily of the Valley (E.).—What are styled "Berlin" or single crowns are best. Get them now, and let a slight frost have access to the tops. It is a good plan to set them into ashes and light soil, or Cocoa-nut-fibre and loam, with the tops just showing through. After a frost, lift in batches, pot into any light compost, and place in a strong heat of 70 degs. to 80 degs. If you keep them back in a propagating house until the flower-spikes are well forward, the bells and spikes will be larger and longer. Expose to light when half opened. They do not force well until after a frost, and need much water.

Lime dressing (P. J.).—A lime dressing can hardly fail to do your stiff soil much good. Except where chalk prevails it is rare that soil is overdone with lime, and this is really a valuable food constituent for plants generally. Still, it will be unwise to employ it too freely. Live at the rate of 1 bushel to 3 rods, as the lime is slacked, although it will have, no doubt because some time slacked, lost some of its pungency. Dry slacked lime dressings are very useful in the spring when slugs are troublesome. It should then be dusted freely about late in the evening, as, if fresh, it kills these pests rapidly.

Cactus Dahlias (S.).—There is some danger in allowing Dahlias to remain in the ground all the winter, as very severe frosts may kill them; or, if they do survive you have so many shoots break up from the root, whereas for all ordinary purposes one or two stout stems is enough. We do not understand why you should have difficulty in keeping the roots, but if others do not suit. Preferably lift the roots now, shake them as free from soil as you can, removing any that cling with the aid of a pointed stick. Turn them bottom upwards to drain the hollow stems, then, when fairly dry, put them as close together as you can in shallow boxes, and fill in round them with fairly dry soil or fine sh-ses, and stand in a cool, dry place where frost does not penetrate. Thus the roots should keep well, and from them in the spring, when placed in a frame or greenhouse, no difficulty should be experienced in getting good cuttings.

TREES AND SHRUBS.

Bigonica radicans not flowering (H.).—Surely the plant has made no growth for two summers if its roots are evidently in an unhealthy condition. If the weather remains open, lift it at once, clear away the old soil, and replace it with fresh loam, to which add some leaf-mould and a dash of silver-sand. Be careful that the roots are not injured in the transplanting, and spread them out carefully in the new compost. The ground around the plant had better be mulched during the winter.

FRUIT.

Black Hamburg Vines (S.).—You did wrong in taking two shoots or laterals from one spur. The strongest only should have been saved and the weaker pruned out. Evidently you have overtopped. If the border has become close, just fork over the surface 2 inches deep, and then spread over a dressing of fresh soil mixed with wood-ashes, horse manure, and soot, also some fine mortar rubbish or sharp sand. That should in the spring greatly help to form new roots. Let only one-half the crop you have had this season remain next year. You will probably find finer berries and bunches, and they will get better colour or finish.

Pear tree (W.).—North wall is hardly the best position for a Pear-tree, as the wood and buds need more warmth than can be obtained to thoroughly ripen them. If you could lift the tree with great care and remove to an east or west wall, it might do better. Failing that, it may be better to lift the tree entirely and replant it at once where it now is, as it seems evident the roots have gone too deep. When the tree is lifted, cut off all roots that strike downwards. Also, in replanting, do not bury the roots deep, neither add manure; but after planting lay a mulch of long manure about over the roots. Leave nailing until the soil is settled, and pruning should be moderate and done at the same time.

Wall Plum-trees (A.).—The laying-in of the summer shoots on wall Plum-trees that are kept for producing fruit, should have been done at the end of the summer to promote ripening. However, you should do so now, but only a few of the strongest. Do not attempt to lay in any that break out from the front of the main branches, only from the sides. Cut all others hard back. Generally Plums fruit from spurs, though also from well-ripened young wood. On the shoot nailed in, shorten back one-third at least. Cut back to about two buds or eyes all other shoots. With Plums the wood must not be so thickly laid in as with Peaches and Cherries. Do not allow clustering shoots to form and project out several inches from the tree.

Black Currant-mite (Purples).—If the buds on your Black Currant-bushes are broad, big, and burst, then we fear they are suffering from a bad attack of the Currant-mite, and the case is a bad one. When such buds as these are few only, and they are picked and burnt, often much good is done; but when bushes are badly infested we regret to say there seems to be no other course open but to grub up the bushes and burn them. Could you seed along some of the buds in a little tin or wooden box that we may see whether mite-infested or not? If you have a good lens, and picking a bud will pull it open, then examine it, you will soon see if tiny whitish mites are present. It is best to get rid of the bud that dressings of any insecticide will do no good.

Peach-trees dying (C.).—As your Peach-trees have died away so badly, we should strongly advise you, ere planting others on the same border, to remove most of the soil, and replace it with fresh soil from the vegetable quarters. The soil may well be excavated to a depth of 2 feet, the bottom being left well broken up, several inches in depth, to admit of free drainage. To replant in the old soil would be but to court failure. It is possible that the soil may lack potash, and be too full of iron, but this cannot be told except by personal inspection. In making the border add, if you can, some wood-ashes and soot, also a little bone-meal. As the trees grow they will benefit by a forked-in light dressing once a year of sulphate of potash or gypsum, for potash is a very important element in both wood and fruit.

Pears cracking (R.).—When pears crack it is conclusive evidence that the roots are in sour or crumbly soil, and fail to find the useful food elements. With respect to your Peach, Nectarine, Apricot, and Plum-trees, though on walls, yet they suffer from the same cause. It would be a drastic course to take, but the only remedy can be found in unnailing the trees, lifting them, carefully preserving every possible piece of lateral root, cutting clean off all downward roots, then replanting. Before doing that, throw out several inches depth of the upper soil, and wheel it away, replacing with fresh soil from the vegetable quarters, then replanting. Keeping the roots rather nearer the surface than before. Also replace the top soil in each case with fresh, and before filling in have top soil pulverised. If you can add some wood-ashes, bone-dust, and lime-rubbish, it will be helpful. After the soil has settled down, nail the trees as close together, and lay a mulching of long manure over the roots. The final nailing had best be done in March.

Fruit-trees for a wood fence (C. W. G.).—At the aspect of your wood fence is nearly due east, it would probably be a little too warm for a Morello Cherry, unless you placed it at the extreme south end, where it would be partially shaded from the sun. Morello Cherries do best on a north aspect. On warm aspects they become smothered with aphids. You can plant against your wood fence horizontal-trained Pears, each tree having five branches on each side; also lam-shaped Plums. Of Pea-good varieties are Williams' Bon Chrétien, Louise Bonne, Doyenné du Tomic, Kivers' Early Harly, and Josephine de Malines; and of Plums: Bour's Early Proflie, Victoria, and Monarch, cooking; and Jefferson and Coc's Golden Drop, dessert varieties. With respect to fixing them, as you have about galvanised iron wire stretched along the line of the posts, securing it to the posts and drawing it tight. These wires should be 3 inches apart, and have a couple of coats of dull-coloured paint. Tie the posts with a portion of the ties between them and the wire.

SHORT REPLIES.

Subscriber.—Apply to Anthony Waterer, Nursery, Woking. **Plata.**—Plant your Privet-hedge at once. **E. P. Weston.**—Plant one of the good Water-Lilies, *S. Martiana rosea* or *N. M. carnea*. **Edwards.**—Write to Barr and Sons, King-street, Covent Garden, W.C. **H. S.**—No, the whitewash will do no harm. It is inadvisable to colour it with some sulphur and so forth, the better to destroy the insect pests. **Edwards' note on Begonia Flore Lorraine** in our issue of Nov. 23, 1902, p. 105, and also January 11, 1903, p. 10, both of which can be had from the publisher. **W. F.**—You can buy paint ready mixed for use quite as cheap as you can mix it yourself. Any oil merchant in your neighbourhood could supply you. **Leila Tilden.**—See article with illustration of Hybrid Phytocacti in our issue of Sept. 6, 1902, p. 363. **T. W.**—You cannot do better than get "Vines and Vine Culture" from its author, A. F. Barron, 13, Sutton-court-road, Chiswick, price 5s. od., post free. **Holmesdale.**—Yes, the soil you have will answer well. Plant at once. **F. E. A. T. K.**—"The Chrysanthemum," by E. Molyneux. **A. Molyneux.**—No. It would for such a house be necessary to have a small boiler with hot-water pipes round the house. **Old Cur.**—1. If the weather is open plant at the time you mention at once. 2. Mix the lime and soot in equal proportions, and stre it over the bushes white dust. 3. Divide the Agapanthus in the spring. 4. Libum cædium. 5. The best time to plant is when the flower buds have died down, say early in the month of August. **H. A. T.**—The colours will improve as the sun gives it power. **V. J.**—The best plan will be to buy seedlings, which can be had more cheaply, and with less trouble than you can raise them yourself. **Justice.**—Not gardening query.

CORRESPONDENCE.

Questions.—Queries and answers are inserted in *GARDENING* free of charge if correspondents follow these rules: All communications should be clearly and concisely written on one side of the paper only, and addressed to the EDITOR OF *GARDENING*, 17, Furnival-street, Holborn, London, E.C. Letters on business should be sent to the PUBLISHER. The name and address of the sender are required in addition to any designation he may desire to be used in the paper. When more than one query is sent, each should be on a separate leaf of paper, and not more than three queries should be sent at a time. Correspondents should bear in mind that, as *GARDENING* has to be sent to press some time in advance of date, queries cannot always be replied to in the issue immediately following the receipt of their communication. We do not reply to queries by post.

Naming fruit.—Readers who desire our help in naming fruit should bear in mind that several specimens in different stages of colour and size of the same kind greatly assist in its determination. We have received from several correspondents single specimens of fruits for naming, these in many cases being unripe and otherwise poor. The difference between varieties of fruits are, in many cases, so trifling that it is necessary that three specimens of each kind should be sent. We can undertake to name only four varieties at a time, and these only when the above directions are observed.

PLANTS AND FLOWERS.

Impatiens Sultan (S.).—This is a very easy plant to grow. During winter it needs a temperature of 55 degs. to 60 degs. Young growth runs very freely early in the spring. Do not grow in too large a pot. This is one of those plants which thrive best when the roots are partly restricted. Give a rich compost. Leaf-soil and good loam in equal proportions, with a little well-decayed manure and coarse sand, make a good compost.

Cutting back Stephanotis (A.).—You must not prune the Stephanotis. It is the long growths you have now that will flower from the axils of the leaves. If you cut away these growths you sacrifice blossom, and merely get more flowerless wood of the same character. *Alamandas* should be pruned in January or February, cutting the previous year's shoots back to within two or three joints of the old wood.

Potting Amaryllises (G. F.).—With the advent of the New Year these require attention, in the way of repotting and placing in a gentle heat. Repotting must be carefully done, using good soil that is fairly moist. When you have turned out the bulbs examine the base of each and remove all decayed and decaying matter. Then place some potting soil in the pots in the form of a cone, the top of the cone as high as the rim of the pot. Place the bulb on this cone, with the roots hanging down the side, fill up with soil and press firmly. Treated thus the bulb will be about half its depth out of the soil. Place the pots in a gentle heat, the bottom of the pot should be about 55 degs. Do not water until the young growth begins to appear. As growth increases lower the

VEGETABLES.

PARSNIPS.

Most invariably in high-class gardens asparns are grown too large and long; hence these roots find when presented at table poor appreciation. The prevailing tendency to prefer long, large roots at exhibitions to smaller ones is primarily responsible for this production of what is, after all, undesirable to the table. It is often the case that roots curly of the most perfect form, ranging from 10 inches to 36 inches long, and straight as all can be, are seen at exhibitions. But through these long roots almost always runs a core of rather woody matter that is not edible, whilst the surrounding flesh is little better than so much watery pulp, devoid of all sweetness, flavour, or solidity. To produce roots of that nature for consumption is no gain, indeed, it is the reverse, much as they may be admired at exhibitions. Parsnip soil should always be deeply worked, because depth is essential to the production of any vegetable root. All tapering roots, of which the Parsnip is an admirable example, should be quite free from side roots and be dependent entirely on its deep point or tap-root for obtaining its regular supply of food from the soil, hence the need for deep working of the ground. The soil should not be enriched with fresh manure, but in just before the seed is sown. Far better Parsnips follow some diverse crop, such as Peas, Spinach, or small Cabbages, that is well manured previously. The primary addition to the soil when it is being trenched for the winter should be bone flour and about 3 lb. per rod, mixed, well incorporated to the subsoil. The great aim of the cultivator should be to obtain plenty of quite solid, well-sized, handle-some roots, ranging in length from 10 inches to 12 inches long, and in the shoulder, and free from side roots, such as these, when properly cooked, are not only delicious, but they are very nutritious, the flesh being less watery than large roots are. One of the best of all Parsnips is Tender and true, a selection from the Hollow-crown variety. It is whiter, of richer flavour, and so the most nutritious Parsnip in cultivation. That shows how far the seedman can help in the desired direction, although Parsnip varieties are very few. It is quite early enough to sow seed at the end of March in the south, and a fortnight later in the north, sowing in shallow drills 12 inches apart. When the seedlings are 2 inches in height, thin to 6 inches apart, keeping the hoe freely used between the rows during the summer. Little else can be done then until roots are needed for use, and in November is soon enough to begin doing so. Parsnips may be lifted as needed, but if really early weather prevails, then a portion of the seed should be covered with long litter. Scrape the roots only and cook them whole, gently lifting the water boil away and leaving them almost dry in the pot. A. D.

Sowing early Peas.—It was an old-fashioned custom, and far from being a bad one, when early Peas were sown to have at

hand a quantity of dry sifted coal-ashes, and to dress these along over the rows after covering with soil, forming a neat and not deep ridge. The effect of such a surfacing was to check the frost, and to throw off heavy rains or snow water when thaws followed snow. If such forms of protection to newly-sown Peas were regarded as essential in the old days, when only hard rounds, much harder in character generally than are modern Peas, were sown, what in the way of protection may not be needed now when in gardens at least almost only the somewhat wrinkled Marrows are sown? Another excellent feature of this form of ash covering is that so soon as the tops of the Pea plants show through, if a rake be lightly run through the ashes all the tops are at once liberated, and whilst less liable to harm than by birds, leafage all the sooner appears, and the plants grow away strongly. Sowing deep is not a good practice, as a weight of soil often injures the plant stems.—A. D.

POTATOES IN POTS.

This is a convenient way of forwarding a few early dishes before those in pits or frames are ready, and pots are usually to be had when the Chrysanthemums are being turned out. Ten-inch pots are suitable for this work, three parts filling them with good loam with a little bone-meal or wood-ashes mixed with it. Put one tuber into each pot, mounding up the plants when about 6 inches of growth have been made. A temperature of 50 degs. to 55 degs. will do, and where a Peach-house or vinery is started at the New Year, it will be found a very suitable place to stand the pots. No water will be necessary until the tubers push through the soil, and when in full growth a plentiful supply must be given. As the Peach or Vine require more heat I move the pots into another house closed about the middle of February, eventually into an unheated house early in March, where full ventilation can be given. The haulm must be supported with branched sticks or strands of raffia placed around. I have tried many varieties for this early crop, and none has given better returns than the true type of Sharpe's Victor, of dwarf habit, and the flavour good. It requires eight or ten weeks before the tubers are fit for table use, and the soil should be kept on the dry side when it is seen that the haulm is ripening, which will assist in imparting a better flavour to the Potato. The tubers are better if started a bit before planting in a pot, standing them upright in shallow boxes on a shelf, shaking down a little leaf-soil among them for the roots to lay hold of, and transferring to the pots before they have a chance to get matted together. J. M. B.

NOTES AND REPLIES.

Mushrooms in paddock.—I have a small paddock of about 2 acres, in which I am anxious to naturalise Mushrooms. Could you advise me on the method of procedure? What number of bricks I should require? How and in what month to plant the spawn, and how long after planting would they be ready to gather?—W. B.

[The first step is to procure spawn that will run freely when placed in a suitable medium.

Early June is an excellent time to insert the spawn in pastures, breaking it into lumps about the size of a lion's egg, then raising the turf with a spade, and placing a lump underneath about 3 inches or 4 inches from the surface. Take care to make the soil quite firm again by well treading or beating it down with the back of a spade, otherwise the spawn will not run freely into the surrounding soil, and is liable to entirely fail. The distance between the lumps of spawn may vary from 2 yards to 6 yards apart each way. When the spawn has once got established, the field may be expected to yield Mushrooms for many years afterwards if given a dressing of agricultural salt every season at the end of March or early in April.]

Green Cape Broccoli.—I send you two specimens of a Green Broccoli which may be of interest. It appears to be unknown in England, but it is grown and used almost exclusively in Southern Italy. There it is considered to have a different and far superior flavour to ordinary Broccoli. I agree so fully on this that I have given up growing the ordinary kind, except for May and June. Even Cauliflowers appear to me insipid by comparison with this Green Broccoli, but after all this is a matter of taste. I get seed from Italy, and can grow it almost all the year.—SIR GEORGE ERRINGTON, *Ramsport, Gorey, Wexford.*

[The variety you send is, we think, what is known as the Green Cape Broccoli, a greenish columnar-headed form which comes into use during October and November.—Ed.]

Ground for Peas.—No time should be lost in preparing the plot that is to be cropped with Peas. Last spring an article from my pen appeared in these pages, advising the ground to be well dressed with decayed farm-yard or stable-manure, and I see no reason to alter my opinion upon this point. If the ground can be double dug, burying the manure between the two spits, so much the better for the crop, and on heavy soils it should be ridged, when it breaks down very much better at sowing time. For the earliest crop a warm, sheltered border or corner should be chosen, and preference given to the dwarf varieties, such as Sutton's Harbinger, Carter's Daisy, Chelsea Gem, English Wonder, and the like. Do not sow too close from row to row: 3 feet is none too much for the sun and air to play around them. I like to get these into the ground before the end of January, being guided by the weather and the state of the soil. In drawing drills see that the bottom is quite flat and the Peas sown evenly, not jumbled together, as is often the case. Where mice are troublesome, roll the Peas in red lead that has been moistened with paraffin, and set figure 4 mouse-traps on either side of the row as soon as they break the soil, baited with bacon or a crust of cheese. To follow these dwarf varieties, sow a month later Exonian, Gradus, Glory of Devon, Criterion, or Duke of Albany. For the latest Pea crop let the ground be trenched 2½ feet deep, and well manured, so that in case of a hot, dry summer and autumn, the roots will have something of a substantial nature to sustain them.—J. M. B.

PLANTS AND FLOWERS.

OUTDOOR PLANTS.

COLCHICUM (MEADOW SAFFRON).

When the Meadow Saffrons begin flowering the approach or the presence of autumn is well known. Coming at this time, too, not a little increases their value, from the garden point of view, for then it is that flowering bulbous plants are by no means plentiful. This is especially true of the dwarfier things in the garden, for of tall subjects there is a good supply. Not merely in their time of flowering are the Colchicums valuable, but anyone may succeed with them. Among suitable places may be mentioned the rock garden, the wild garden, the border, and, as implied in the popular name, in the Grass. In any of these places the ruddy tones of purplish-rose, or the paler shades, wherein we mostly find the chequered members of the race, are ever pleasing, more so if freely grouped. In the Grass, or furnishing a bank in front of shrubs, these Meadow Saffrons look well when in flower: nor is the lolder leafage of some kinds to be regarded as meaningless. Again, we have the marked characteristic of this fine leafage appearing after the flowering, a wise provision of Nature, when we remember the wonderful disproportion between the two—flowers at 9 inches high, and the leaf tuft of an established group of *C. speciosum* more than 2 feet high, and fully as much across.

WHERE TO PLANT. I firmly believe that, as a rule, we are too conservative in our recommendation for "light sandy soil" for these plants. I do not say the Colchicums dislike it, but to those who have never seen the more vigorous sorts growing in good stiff clay soil, or, again, in Grass in the vicinity of a bog garden, the thing would come as a sort of revelation. In certain instances these plants are more influenced by sub-soils than by the actual soil in which the bulbs are set. Perhaps the one place not suited to these plants is the lawn, which is constantly being cut and rolled. In such a place the sod becomes very close and consolidated. In this class of soil most bulbous plants cut a sorry figure, and are not a success. The best time for planting is August.

Group of Colchicums.

Large quantities are, however, planted after that time, but such belated work is not actual evidence. When transplanting and division of the established groups in the garden are a necessity, the best time for lifting the bulbs is in July, when the foliage is well matured. This done, the replanting may follow in the

course of a month, always supposing the immediate replanting is not convenient. Dry corns may be replanted far into the autumn months, but these late planted ones take some time to recover. The genus Colchicum, geographically, has a somewhat wide distribution,

Colchicum Parkinsonii.

the majority being natives of Southern and Central Europe, while others are found in Northern Africa, Persia, and even the Himalayas. The following are some of the best kinds—

C. ALPINUM.—A pretty dwarf species: the flowers vary from rosy-purple to nearly bluish-white. The plant is about 4 inches high, flowering in early spring or even in winter, accompanied by the foliage. This species is somewhat freely distributed through Southern Europe.

C. AUTUMNALE.—This, with its many varieties, is one of the most useful of all for naturalising. Its free flowering, ready increase, and generally vigorous constitution fit it well for the climate of Britain. Indeed, *C. autumnale* is a true British wilding, and distinct from the well-known typical kind is a variety flowering in spring, *C. a. vernalis*, chiefly distinguished by the narrower segments to the flower and paler colour. Apart from these are the white, the rare double white-flowered form, the double of the type, roseum, and roseum plenum, etc. Native of Central and Western Europe.

C. BIVONÆ.—A fairly vigorous-growing species, producing large rosy-lilac flowers that are only delicately tessellated. Autumn-flowering, with foliage appearing late in spring. The leaves are distinctly linear. Southern Europe.

C. BYZANTINUM, also called *C. latifolium byzantinum*, is a very old species and one of the most vigorous. The flowers are of a beautiful rose colour, and compare favourably with those of a small *speciosum*. The corm is large, and the foliage even more vigorous than in typical *speciosum*. A most profuse autumn bloomer. Native of Asia Minor, Greece, etc.

C. CILICICUM is very near the above, narrower, perhaps, in the segments, and lacking some of the perfect form, yet one of the best

and most profuse flowering. Flowering in autumn. Cilicia.

C. CROCIFLOREM.—It is not improbable that this is a near relative, if not indeed synonymous with *C. alpinum* or *C. montanum*. It is a winter or spring-flowering kind of about 4 inches high, freely blooming, of a purplish tone, freely striped externally.

C. DECAISNEI.—A distinctly coloured species between flesh or pale rose. A rather early autumn-flowering kind from Palestine.

C. HYDROPHILUM.—A new kind and quite free flowering. The flowers, reddish pink in colour, sweetly scented, and about 3 inches high, are produced in spring. The species is found in damp spots in its native home in Asia Minor.

C. HAUSSEUSCHILII.—A rare species from Persia, flowering in autumn. Flowers on first opening nearly white, afterwards changing to a good purplish tone.

C. PARKINSONI.—Among the chequered forms this is one of the most distinct, while coming quite close to *C. variegatum*. In leaf time, however, it is more easily distinguished than when in flower, the leaves being disposed horizontally or nearly so, and more undulated, in place of the more erect, less undulated leaves of *C. variegatum*. The petals are reflexed and prettily chequered with rose-purple and white. This kind in some localities is tender, and, coming from the Greek Archipelago, should receive a light winter covering in severe weather. *C. tessellatum* and *C. agrippinum* are synonymous with this kind.

C. SIBTHORPII.—This is one of the handsomest of all, and certainly the finest of the chequered section. The plant is as yet rare in gardens. It is one of the most beautiful of the race, the predominant colour being rose, the broad segments freely chequered with purple. The species comes to us from Greece and Macedonia, where in the mountainous regions it is found at varying altitudes to a height of from 4,000 feet to 5,000 feet above sea level.

C. SPECIOSUM.—This I regard as the finest of the Colchicums. The type is surpassed by its variety *rubrum*, and I have also heard of another, *C. s. maximum*. In each of these the colour, usually a purplish-rose, is very warm looking in the autumn. It is a vigorous-growing kind

Colchicum autumnale.

and generally suited in most gardens. A deep rich soil, where moisture at leaf-time can be given, suits it best. Indeed, upon the fullest development of leaves do we get the finest flowers. The flowers are often 9 inches high and sometimes more, and well supported by a strong tube. There is a pure white variety

of this plant, but it is very scarce. The type is from the Caucasus, and, happily, is a good doer and fairly cheap.

C. VARIEGATUM.—This is a very old garden plant. The flowers come in autumn, are rosy-purple and much chequered.

Other kinds are *C. umbrosum*, *C. amabile*, *C. Bornmulleri*, *C. giganteum*, a present-day novelty I have not yet seen, *C. Troodi*, and *C. Steveni*, a spring or winter-flowering species from the Orient. E. J.

PLANTING THE CLEMATIS.

EVERY nurseryman and every florist know of the loss of plants of the Clematis, both by themselves and their customers. This loss is more likely to occur when the plants are set in the autumn than when done in spring, having in mind the large-flowered sorts principally. These are largely grafted on *C. Flammula*, and the fleshy roots of this stock do not take kindly to fall transplanting. Why this I cannot say, and it may not be so generally; but it has been my experience that to set out the plants in the autumn is almost equivalent to throwing them away. That the cold soil has something to do with it is believed, because when potted and placed in a greenhouse the result is different. Careless planters cause the death of many Clematises by not spreading out the roots. They set them in a bunch, as if the cluster was one root, resulting in the inner ones getting not a particle of soil to touch them. These roots rot, and the whole mass becomes diseased. The roots should be well spread out, so that each is encased in soil, and is good for covering them with, as it works in well around the roots. Many trees, evergreens, such as Hemlock and Arbor-vita, especially, are often destroyed in the same way. They have large clusters of small roots, make in appearance, and it needs great care to save the soil reach every one. J. MEEHAN, in the "Florists' Exchange."

NOTES AND REPLIES.

Name of Pink.—Would it be possible for the writer of that excellent article, "Garden Edgings," p. 579, to give through your columns name of Pink there described and where procurable?—M. H.

—Would the writer of the interesting article on "Garden Edgings," in your paper of Jan. 3, kindly inform your readers of the name of the Pink described as "flowering all the summer," also where obtainable? I have a border along a drive some 100 yards long, which is ready for a time, but after the flowers are at an end looks pretty till the Pinks are cut back. The longer lasting Pink described must be a decided advantage.—C. W. S.

Grass, in a sunny aspect and in no way protected. It has flowered twice, and ripened seed, which on sowing has come up into strong young plants. I have also, for the last two years, had a plant of Clematis balearica on a south wall. It is now in bloom, and last year it flowered in February. A. B. TRESTRAIL, Southdale, Clevedon, Somerset.

Sowing croquet-lawn (Cubic).—The practice of burning is chiefly adopted for clayey soil, and for the purpose of so far changing its texture that afterwards it is not so retentive of moisture. Even then it becomes but a body of from 2 inches to 3 inches thick, or even less per acre. If your soil is of a light porous nature, then you would find it difficult to burn it, as it would run so close together. Clay put up to burn in lumps admits a free circulation of air, and also of fire-heat amongst it. You would, for the purpose in view, find it needful to burn a thickness of surface-soil of fully 4 inches, and that would mean a great bulk. To do it well, it is needful to make a fire of wood, on that put coal in lumps and coke, then when well alight pack about it the soil in clumps, adding to it from time to time until all had been burned. But when done and respread, we are not sure that grass-seed will germinate in it freely, and if it be needful to add unburned soil, then all your labour will be lost if the added soil contain weed seeds. We should prefer to make the base for the lawn by well forking, levelling, and treading, then raking coarsely the soil, doing that a month before it is time to sow the seed, and the middle of April is early enough for that. Time enough would then be given for any weed seeds in the soil to germinate, and if a day or two prior to sowing the seed the surface were well hoed over, the weeds would partially dry, then be raked off. The grass-seed should when sown have the soil to itself, and be well ahead of any weeds that might follow, which could be pulled out after they become large enough.

where air can reach it. In a few days it will crumble to pieces. Now take and give a light dressing over the surface-soil, and particularly in those parts where the slugs most do coagregate—viz., round about the tufts of perennials, etc. Prior to doing this, free the

Colchicum autumnale roseum.

border and plants of dead or decaying foliage. Such things afford the best shelter for slugs. Repeat the dressing of lime a fortnight hence, and by the use of the lime alone you will get rid of large numbers. It is more effective in this way than when mixed with soot. Sprinkle a little in the crowns of the plants also, though chiefly about the base of the plant.]

Leggy Wallflowers.—I have some Wallflowers and other plants which are very leggy. Can I plant such very deep in the ground to counteract the legginess, or is it detrimental to do so?—AMATEUR.

[If the stems are sufficiently pliable, a better plan will be to bend them round and peg them into the earth, or you may lay the stems in sideways, so that there would be no great depth of soil above them. Deep burying of the stems is certainly not desirable, less so where heavy soils obtain. Any expedient is better than this.]

English and Spanish Irises.—I have a lot of English and Spanish Iris bulbs, but my soil is wet, clayey, and holding. When shall I plant the bulbs? I thought February. Last year many rotted from being in the wet, sticky ground all winter. What treatment should they have after flowering?—AMATEUR.

[These Irises should have been planted weeks ago. If you keep them till February many will be worthless—a dry rot takes them. Your soil is obviously not suited to these plants, and your only chance of success would be to mix sand and old mortar very freely with the soil. If, in conjunction with this, you could plant 3 inches deep in a position sheltered from south-west rainfall, a better opportunity would be afforded of a good flowering. It is a mistake to keep these Irises long in the dry state—in fact, we believe more roots are lost in this way than when planted in November. If you cannot do as suggested, the next best thing is to cover the bulbs deeply with sand. In the end of July the bulbs may be lifted, cleaned, and placed in sand till required for autumn planting.]

Delphinium Blue Butterfly.—About two years ago I noticed in your paper an account of a new annual Delphinium "Blue Butterfly." Last spring I got a packet of the seed and raised some, filling with them two small beds in my garden. I was charmed with them, especially as one often runs short of good blue flowers. This Delphinium is perhaps not quite of so rich a hue as our old favourite *Salvia patens*, but it is a lovely colour all the same. Growing only about 1 foot high, it is a good plant for a flower-bed. Any of your readers who try it will, I think, find a welcome addition to their gardens in "Blue Butterfly."—AMATEUR.

Dianthus deltoides, cutting down (Rockery).—All the old stems may be cut off the straggly *Dianthus*, which is probably *D. deltoides*. This may be done at any time after blooming. Compact tuft of growth assuring a further supply of flowering stems another year.

Colchicum alpinum.

The New Zealand Flax.—In reply to the questions asked in your paper regarding the hardiness of the New Zealand Flax, I may state it grows well in Clevedon, Somerset. I have had it between five and ten years planted in the

Slugs in garden.—Slugs are very bad here in summer. Can I dust round the actual bulbs and also all herbaceous plants with mixture of soot and lime? They eat all the young shoots.—AMATEUR.

[Your best plan will be to obtain at once some fresh lime, placing it in a box in dry shade

CHRYSANTHEMUMS.

THE FUTURE EXHIBITIONS OF THE NATIONAL CHRYSANTHEMUM SOCIETY.

THE Executive Committee of the N.C.S. have decided to hold their coming exhibitions at the Crystal Palace. At least, so I gather from the report of the last meeting held to discuss the question of the future of this society. What a relief this piece of news will be to those who have so long desired the removal of the exhibition to a building where they could ask their friends to come and see the displays made in October, November, and December for many years past. It is difficult for old habits to realise that the fiat has gone forth, and that the "Aquarium" has seen the last of the National Society's shows. The association of the National Chrysanthemum Society with the Royal Aquarium has, no doubt, been mutually advantageous. Almost, without exception, the members of the N.C.S. would probably recognise the fact that the great popularity of the flower has been achieved by associating its fortunes with those of the Aquarium. The National Chrysanthemum Society for several years past has been subsidised to the extent of £375 per annum, and in many other ways has benefited. Because of this fact the prizes have been increased in number, and in value too—the total value of prizes and medals awarded reaching about £375. Whether this money has been wisely applied is a matter which has disturbed the minds of several writers in GARDENING ILLUSTRATED within the last month or two. The big, unwieldy blooms of some of the varieties have received far more attention than they really merit, to the exclusion of some of the more interesting and pleasing types of the Chrysanthemum. Let us hope that with the change which is now inevitable there may be a complete alteration in the character of the exhibitions.

The remarks of "Essex" in GARDENING ILLUSTRATED for January 3rd last seem to point to the want of knowledge respecting what is required of Chrysanthemum societies and their exhibitions. To say that "Ovont Garden is the only place for small flowers is ridiculous. He rightly says that exhibitions are held to improve floriculture, and to test the skill of the gardener." To say "there is no skill in producing small flowers" is absurd. I maintain that to grow a batch of plants to produce a free display of medium-sized disbudbed blooms of good character—not miserable, weak-necked blooms with little to admire in the plant and its foliage—requires the best skill. "Essex" asks, "What has made the Autumn Queen so popular?" and answers, "Is it not the exhibitions?" The exhibitions have certainly popularised the cultivation and exhibition of large, severely disbudbed blooms, but the growers of these blooms are but a tithe of the large army of cultivators who find the keenest pleasure in growing the kind of blooms to which "Essex" refers rather disparagingly.

All who have had the best interests of the N.C.S. at heart are hoping the executive committee will set their house in order and rearrange their schedule. According to the report of the meeting, to which I have already referred, the Crystal Palace Company are offering, in addition to a certain number of medals, some £200. As this shows a difference of £175 or thereabouts in the amount previously received to supplement the society's prize list, the greatest care will have to be exercised in the compilation of the schedule of prizes for the next series of shows. Many of the "big bloom" classes might with advantage be left out, as there is far too much repetition in the existing schedule. All who are interested in the Chrysanthemum, not necessarily from the point of view of large, disbudbed flowers only, but rather for its general usefulness for decoration, will hope that the freely-grown, disbudbed, and partially disbudbed blooms may receive the encouragement this type of flower deserves. Let these be encouraged and also be properly exhibited, and it is safe to predict an increased popularity for the Autumn Queen, because many people who

cannot find pleasure in the "mops on poles," which now so largely predominate at the shows, would appreciate the many uses to which the medium-sized flowers could be put. The exquisite form and lovely colours of sorts which are too small for the large bloom classes would then be more often seen and their excellent traits deservedly brought to the front.

What a pity it is the society has decided to charge, in addition to a member's subscription, a fee for each class in which such members exhibit. Experience of shows extending over many years, and in societies of a varied character, goes to prove that this charge acts as a great deterrent. An old friend, who was once honorary secretary of a very influential Chrysanthemum society, has always been most emphatic in protesting against anything that might deter growers from exhibiting. His experience was similar to that expressed above, and if the present idea of the N.C.S. is persisted in, there is good reason for believing there will be a considerable falling off in the competitors. As a well-known grower truly said, "the expenses of getting up and down from the Palace will be considerable, and if in addition one has to pay to exhibit, I am sure it will end in failure, because men will not show there at all." This, surely, is a remark of an ominous character, and one which the committee will do well to consider.

W. V. T.

EARLY-FLOWERING CHRYSANTHEMUMS.

WHAT TO DO WITH THE OLD STOOLS.

THESE do not need the long period of growth that many seem to suppose is necessary. Far better wait a little while, and in the meantime take every precaution to ensure the satisfactory development of a good crop of fresh growths on the old stools. Cuttings of this kind will make all the difference between success and failure. In many gardens the old stools are still in their flowering quarters, and these old plants have had a very rough time of it lately. Notwithstanding this fact, one's prospects may be improved by timely lifting of these old stools, placing them in boxes, or, better still, planting them out on the greenhouse benches. Those who do not possess a glasshouse may accomplish the same object by utilising the cold-frames, or, better still, the heated pit-frame. Any soil of a light and gritty kind will do to embed the plants in, and if a good watering with clear water, from a can with a fine rose, can be applied, fresh, short-jointed growths will soon develop. Many of the early-flowering Chrysanthemums are rather shy in producing cuttings, and others, too, are likely to die if left out during a protracted frost. These plants should be the first to be lifted, and special care should be taken in planting them in the better positions on the greenhouse bench or elsewhere. In this category appear such varieties as Mychelt White, Mons. Gustave Grunerwald, and its sports—Henri Yvon, M. Louis Lenaire, and Mrs. R. Mallinson in the Japanese section; and among the Pompons, Lyon, and its sport Alice Butcher, represent two of the sorts needing special care for a time. Ultimately, these plants grow along vigorously, and produce a splendid crop of cuttings. Mme. Marie Masse and its sports, Ralph Curtis, Crimson Marie Masse, Robbie Burns, and Horace Martin, represent the hardiest of the outdoor kinds. One plant in a season will develop a mass of shoots, many of them with numerous roots adhering, sufficient to supply the needs of a neighbourhood. Many of these old stools measure between 2 feet and 3 feet in diameter, and no matter how severe the winter may be, they generally come through it exceedingly well. Readers of GARDENING, in taking in hand the cultivation of plants of Mme. Marie Masse and its sports, should remember that these plants may be increased by division quite easily. This is encouraging for readers who have no glasshouse or frames. It would be better, of course, to leave the division of the plants until the spring. April would be quite early enough, and if the plants be divided with a little care the divided portions will soon start freely into growth.

Referring again to the old stools, which

should be plunged in the soil on the greenhouse benches, etc., these should give an excellent crop of cuttings just as the days begin to lengthen. The fresh and healthy condition of these new growths enables one to start the season's work of propagation with success assured. Assuming the cuttings are not coddled during their period of propagation, it is quite safe to assert that scarcely a failure will have to be recorded during the rooting process. The cuttings should be dibbled into shallow boxes, and if the temperature of the glasshouse can be maintained at about 50 degs. they will quickly root, and be considerably assisted by the more genial atmospheric conditions prevailing outside. The old stools will continue to give successive crops of cuttings, and this may be allowed until a sufficiency of plants has been obtained.

E. G.

NOTES AND REPLIES.

A new late Japanese Chrysanthemum—Mrs. Swinburne.—The variety under notice is another of the choice kinds raised by Mr. H. Weeks, of Thrumpton Hall Gardens, Derby. This Japanese flower is refined and chaste, having very long, medium to broad petals of good substance, which prettily twist and incurve at the ends, making a flower of undoubted high quality. It may be described as a pure glistening white, and as such will be of value for late displays. It is the result of a cross between Miss Alice Byron—which is recognised as one of the best pure white mid-season sorts—and Mme. R. Cadbury, a beautiful late-flowering white sort. From plants housed at the beginning of October, at which time the crown-buds were retained, lovely blooms were gathered about a fortnight before Christmas, and these continued to make a brave show right into the New Year.—E. G.

Chrysanthemums in vases and baskets.—I quite agree with "A. D." January 3rd, page 582, in his remarks with reference to "big, fat" blooms usually exhibited at Chrysanthemum shows. There is no comparison between these so-called high quality flowers and those of the charming spidery, Pompon and decorative Chrysanthemums, of which we see far too few. It is owing to the action of the Chrysanthemum societies catering for these large blooms that the pretty blossoms just referred to are so scantily provided for. Societies will have to mend their ways if the flower is to maintain its popularity, and more classes of a decorative character will have to be the rule. Anyone who has seen a free display of decorative exhibits, in which small and medium-sized blooms are used, will admit that for exhibition and for providing more general interest this class has many advantages. Apart from this, the cultivation of free-flowering kinds is encouraged.—W. V. T.

Chrysanthemums—plants shy in producing cuttings.—Some sorts are naturally shy in developing cuttings, and these same varieties not infrequently are among what are regarded as the best kinds for exhibition. There are also, in most collections of Chrysanthemums, plants which appear to give but the faintest indication of developing cuttings within the period best suited to their requirements, and as they may be regarded as indispensable by certain growers, means should be taken to encourage the production of new growth. To this end, shake out the plants from their flowering pots. If the grower has a portion of his greenhouse bench to spare, and can plunge a few old stools in some light compost on this, he will be able to raise a goodly quantity of stock in a little while. Before plunging the old stools, as just suggested, the ball of soil and roots should be considerably reduced, and what remains of the old ball of soil should also be slightly loosened. Should the old stool be very dry, give it a thorough soaking with slightly tepid water, and after this has drained sufficiently the embedding of the old roots should be proceeded with. Maintain a temperature of about 50 degs. to 55 degs. Where the use of a side bench or the side of a propagating-house, with its accompanying bottom-heat, can be utilised, so much the better. A genial temperature in such a structure, keeping the soil just moist,

not wet, produces fresh and clean growth in a short time. Old stools may also be reduced and repotted into 6-inch pots. This latter method is useful in the case of those growers who cannot conveniently adopt either of the other methods before described. By following any one of the three courses suggested sly sorts can be induced to break out into fresh growth, and cuttings of this kind generally root readily.—E. G.

TREES AND SHRUBS.

THE NEW ZEALAND DAISY BUSH (OLEARIA HAASTI).

This is hardy in most parts of England, and we remember having seen some very fine specimens in the villa gardens round Aberdeen, where it grows vigorously and flowers freely every year. If planted in large groups it has a beautiful effect when covered with its thousands of Aster-like flowers. Even out of bloom it is attractive. In New Zealand, where it is found at an altitude of about 4,000 feet, it forms a small shrubby tree. The flowers, as

It is perhaps *Philadelphus Sataumi*, as noted on the label. I turn to the *Kew Gardens* handbook, and find it has nine other aliases. If a tree bears on its label at *Kew* the name *Amelanchier canadensis*, the handbook warns me that the tree also bears eighteen other names. *Spiraea canescens* has twenty-four other names. The multiplication of examples would be easy. The nomenclature of the flowering Cherries, for instance, is in a hopeless state of confusion. The only certain way of getting what one wants is to wait until the trees and shrubs are in flower, and then make a selection at the nursery. All this is very troublesome. Is it too much to ask one or two of the best of our nurserymen to make a commencement towards bringing their stock into accord with the *Kew Gardens* nomenclature? This would, I suppose, involve a good deal of labour and some cost, but the result would be well worth the trouble. A commencement might be made with the family of Rosaceae, which includes some of the ornamental gems of our gardens, *Prunus*, *Amygdalus*, *Armeniaca*, *Cerasus*, *Padus*, *Laurocerasus*, *Pyrus* *Malus*, etc. I know very little of Conifers, but

increase it. Never cut a slit in the bark into which to insert the seeds, but simply apply them to clean bark, protecting with a piece of fine muslin. Raising the Mistletoe from seed is a slow process, as no external sign of the growth is visible until a year after the seed has fallen away. If you examine the place then you will find that the bark is swelling just beneath the spot whereon the seed was placed, and in the second year the young shoots appear.]

Upright low-growing Conifers.—Are there any upright-growing, well-shaped Conifers, whose growth is limited to 5 feet or 6 feet in height?—H. C. W.

[There are very few Conifers that just conform to your requirements, the nearest being *Cephalotaxus podunculata fastigiata*, *Juniperus communis hibernica compressa*, *Retinospora leptoclada*, *Retinospora obtusa pyramidalis*, and *Biota (Thuja) orientalis elegantissima*. Some kinds that are very amenable to pruning, such as the medium-growing forms of *Cupressus Lawsoniana* and several of the *Retinosporas*, may be kept to the specified height for some years if the principal branches are shortened back when necessary.]

Carpeting plants for bank.—

What are the best evergreen carpeting plants for a bank, to grow in large spaces between and in front of Conifers? The Conifers are low, and the plants would get plenty of sun?—H. C. W.

[Evergreen plants of a shrubby character suitable for the purpose you name, are: *Cotoneaster microphylla*, *Cotoneaster thymifolia*, *Euonymus radians variegata*, and the variety *Silver Gem*, *Ivy* of various kinds, *Hollanthemums* (Rock Roses), of which there are many beautiful flowering forms, *Vinca major* (the *Periwinkle*), *Vinca minor*, of which there are many varieties. The *Rose of Sharon* (*Hypericum calycinum*) is almost evergreen, and is such a delightful low-growing shrub that it must not be omitted from any list, however select. It is certainly one of the finest of all the *Hypericums*. Such a position, too, would suit the various hardy *Heaths*, and if the soil is of a heavy nature it may be made suitable for them by incorporating with it a portion of vegetable matter in the shape of either good decayed leaf-mould or peat. There is a considerable choice of these *Heaths*, all of which delight in a sunny spot. Specially worthy of mention are the *Ling* or *Heather* and its numerous varieties, all of which flower during the autumn months, the *Troy Heath* (*Erica cinerea*) that blooms about midsummer, *St. Dabie's Heath* (*Daboecia polifolia*), whose purple blossoms are borne from early summer till late in the autumn, and the same may be said of its white variety (*alba*). *Erica carnea*, that pretty *Heath* that flowers soon after Christmas, must, as well as its white variety, be included in the list, while *Erica ciliaris*, *E. tetralix*, and *E. vagans* are all good. Of Conifers, *Juniperus Sabina prostrata*, *Juniperus Sabina tamariscifolia*, and the *Weeping Yew* (*Taxus Davoustii*), if on its own roots, may be all recommended.]

Outdoor climbers for various aspects.—Some quick growing, robust climbing plants fail, for the reason that they are put into wrong positions. Take as one example amongst *Roses*, *Crimson Rambler*. No one who has had much experience with it would recommend its being planted on a south wall. Yet generally I have seen it so grown, but, of course, both flowers and foliage soon blister in the hot sun. A north-west or even an east aspect is better for this *Rose*. *William Allen Richardson* is another *Rose* that bleaches very much when grown on a hot wall, and besides this the buds are unduly hurried. Plant on north and north-west walls *Ivy* in variety, *Ampelopsis*, *Jasminum nudiflorum*, but do not confine the last to this aspect as on south walls early blossoms of the *Jasmine* are most acceptable,

The New Zealand Daisy Bush (*Olearia Haasti*). From a photograph sent by Miss Sophie M. Walker, Lough Eske, Co. Donegal.

may be seen by our illustration, are very numerous, in terminal corymbs, the ray florets 1/2 inch long, white, the disc yellow. The plants, as a rule, bloom in August, and remain in perfection several weeks. It appears to succeed in any kind of soil, provided it is not a rank clay, and soon forms a dense bush. It is advisable after flowering to pick off the flower-heads, as it would be a great tax on the bushes to allow them to produce seed. In cold districts it is best planted where it can have the friendly shelter of other and taller growing plants. T.

NOMENCLATURE OF PLANTS.

Now that more attention is being given to flowering trees and shrubs for the brightening of gardens and grounds, it seems desirable in the interests both of buyers and nurserymen that trade catalogues should be revised, so as to bring them into accord with some standard nomenclature. As matters stand at present, names in catalogues are absolutely bewildering. What has happened to the writer of this note must have happened to many gardeners before, and will trouble many more in the future. I see some beautiful things in flower by *Kew*.

I can see by looking through the lists of one or two of our very best nurserymen that they are not free from the old confusions between *Pinus*, *Picea*, and *Abies*. TURKEY.

[This is just what our best nurserymen are now doing, but it is very difficult to get all to follow the *Kew* list. The Continental growers, too, in many cases do not follow the same nomenclature as our English growers, and it would be difficult to get them to do so.—E. G.]

NOTES AND REPLIES.

Propagating the Mistletoe.—In your issue of Jan. 11 and Feb. 8, 1902, you had some notes on Mistletoe culture, from which it appears the seed must not be sown till March or April. In this district, however, little Mistletoe is found, and one can hardly obtain ripe seed at that time. Will seed saved from the boughs answer the purpose, or will the berries then be too dry to adhere to the bark? What would be the result of sowing early in January? Kindly let me also know whether the method of sowing is simply to squash the berry on to under side of bough and protect as instructed?—T. C. USURE.

[If you put on the seeds now they are not quite ripe and probably will fail. You can preserve the berries, or anyone who has a tree with Mistletoe on it would send you some berries in April, which is the best time to

On north and north-east walls the Flame-flower (*Tropæolum speciosum*) is often to be seen in blaze of colour: for east walls, too, Honey-suckles, *Cydonia japonica*, and *Kerria japonica*, with Clematises, are suited. We know, too, that often in east aspects strong growing Roses like Gloire de Dijon, Mme. Berard, and Aimee Vibert often excite admiration. On a corner of a west wall I have a Clematis belonging to the lanuginosa group—Lord Nevill—which never fails to bloom well.—LEAHERST.

INDOOR PLANTS.

CLIMBING PLANTS IN THE CONSERVATORY.

The climbers in the conservatory, if not already thinned out or pruned according to their several needs, should have this attention given to them. Indiscriminate pruning is altogether a mistake; thus to prune *Ilabrothamnus elegans* now would be utterly wrong; rather save every shoot and prune immediately after the flowering season in the spring. Another instance is the well-known but none too frequently grown *Bougainvillea spectabilis*, which, in contradistinction to *B. glabra*, flowers from the terminals of the previous year; here, again, pruning would be wrong. Instances need not be multiplied beyond these two. *Lapagerias* should be carefully thinned, merely taking away the weaker or spray-like shoots. See that this plant does not get dry at the roots: it should never suffer from this cause. Look closely after young shoots, which in favourable positions may soon be pushing up from the base, and guard against slugs and even snails; these shoots appear sometimes farther away than one would for the moment think of looking. Where large or medium-sized plants are in pots or tubs and there is any idea of planting out, it had better be attended to at once, using rough loam and peat, turfy and fibrous, with a liberal addition of road-scrappings or silver-sand. *Plumbago capensis* may be pruned hard and be thinned freely, too much wood if left being a check to strong growth, which is the best for flowering. *Troscasias* should be pruned moderately, spur-pruning rather than cutting hard back being advisable. *Solanum jasminoides* should be cut back freely, otherwise it becomes master of the situation. *Cobæa scandens* requires similar treatment, but the best check to this climber is to drap its shoots, letting them as far as possible hang downwards, thinning out the rest as growth proceeds. Roses in conservatories which are not kept absolutely cool are rather awkward to manage at times, being predisposed to start into growth too soon. To remedy this in a measure it is best to keep them quite on the dry side for the time being. Any climbers which are known to be a trifle tender should, if possible, be dropped from the roof to where it is a little warmer. Thus treated, they may be kept safely. The white scale often troubles conservatory climbers that are of a hard woody character. Wherever this pest exists no time should be lost in attacking it with determination whilst work in other quarters is not so immediate and pressing.

TUBEROSES.

Few flowers are more valued in autumn and winter than the Tuberoses. Especially is this so where there is a large and constant demand for such as are useful in button-hole work. Tuberoses, it must be admitted, are suited to this class of work, and altho useful as they in wreaths, crosses, or bouquets. It is now possible to have them in bloom almost all the year round, and though, of course, in common with all flowers, they open very slowly in the depth of winter, yet it is satisfactory to know that a fair percentage of their blooms expands tolerably well. To secure the flower-spikes from accident, a stick should be placed to each, with a loose tie to admit of future growth, and if the pots are stood closely together little harm should result. At this time also keep them free of the side growths that form about the bulbs to the detriment of the flowering stem and blooms. Give the plants abundant supplies of water at the root and weak liquid manure every other day. Syringe freely and regularly, so as to check as

much as possible the progress of red-spider, thrips, and the like, which are almost sure to infest them. An occasional watering overhead with clear soft-water will also conduce to the same end. Best of all, perhaps, is an occasional syringing with Quassia chips and soft-soap. Take a 6-inch potful of the Quassia chips and place in an old saucapan with soft water, and boil steadily till the whole of the chips have sunk to the bottom; then drain it off and add a large teaspoonful of soft-soap, stirring well till dissolved, adding sufficient cold soft water to make two gallons of the whole, but if not sufficient, increase the proportion of chips and soap till enough has been made to give a good syringing all round. Provide abundance of air on all favourable occasions, and daily while the plants are in frames at closing-time give them a nice sprinkling overhead with a fine rose. This will also tend to keep insect enemies in check. From time to time the most forward may be introduced into warmth as required.

NOTES AND REPLIES.

Creepers for a balcony.—I should like to know what creepers would be suitable to grow in boxes on a south balcony next summer? I want something to cover the walls of the house well. Is it any use trying *Solanum jasminoides* in a box?—W. J. B. L.

[We hardly think *Solanum jasminoides* sufficiently quick-growing. Better plants would be *Cobæa scandens* and its variegated form, *C. s. variegata*, together with Climbing *Nasturtium*, the Canary Creeper (*Tropæolum canariense*), thickly planted in line, or some good two-year-old plants of Ivy-leaved *Pelargonium*. These last are very free.]

Carnation Deutche Bruant.—I have heard it stated that this is what is termed a "miffy" doer, but with me it is all that can be desired. Having propagated it last spring freely, with a view to test its capabilities as a winter bloomer, I am now in a position to say that it is quite first-rate, for it is as free as *Mlle. Carlé*, while the individual blooms are thrice as large. The flowers are clove-scented, pure white, beautifully formed, and of the greatest value for button-hole making at the present season. Plants with about five expanded blooms on them are very valuable for house decoration just now, and the flowers being so sweet-scented render them doubly valuable.—A. W.

Spot in Carnations.—Can you tell me how to cure spot in Carnations? I have a large number of *Malmaisons*, and they have got spot badly. They have been in cold-frames, with plenty of air and very little moisture at the root. The disease appeared just after the layers were potted up at the end of September. Can you recommend me a book on the culture of *Malmaisons*?—A. VENABLES KYRKE.

[As your plants seem to be badly affected with this disease, we would advise you to throw away the very worst ones, and, if possible, remove the others to a greenhouse or similar structure, where a little fireheat can be turned on during wet or foggy days, so as to dispel superfluous moisture. In a house the plants are not likely to keep nearly so wet as when in cold frames, and this, we think, is partly the reason your plants are so bad. In cold pits or frames it is next to impossible to keep the Grass dry, consequently the plants are laden with moisture day and night—a sure forerunner of this dreaded disease. Do not water until really necessary, and then use every care that the foliage is not wetted in the operation, using a long-spouted small can for the work. We would cut off the worst patches and then dust the entire stock with a mixture of soot and sulphur, washing this off after a couple of days, laying the plants on their side and syringing with clean water, repeating the dose twice or even thrice. We have known this to be effectual in many cases. Give the plants abundance of ventilation on fine days, and the night temperature should be from 40 degs. to 50 degs., according to the weather. Place the plants in the lightest position, and within 2 feet of the glass roof if possible, allowing plenty of space between each one, overcrowding being another cause of this Carnation going wrong in the way yours have done. We do not know any one book on *Malmaisons* alone, but the "Carnation Manual" should answer your purpose, as all classes of Carnations and their diseases are fully dealt with in it.]

ROSES.

ROSES AS ISOLATED SPECIMENS BETWEEN FIR-TREES.

(REPLY TO "BEGINNER.")

THERE is abundant variety for such a purpose. Foremost among the groups are the *Rosa rugosa*, or Japanese Roses. Great improvements have been made in this tribe during recent years. In some cases we have lost the charming display of fruit or seed-pods, but, on the other hand, we have gained more exquisite blossoms. Varieties such as Conrad F. Meyer, the delicate-coloured Mercedes—as beautiful as a Tea Rose the snowy white *Blanc double de Courbet*, the brilliant *Mrs. Anthony Waterer*, and the single pink and white should not be omitted. Other good Roses for such an object as you have in view, supposing the space available is fairly considerable, are: *Dawn*, *Robusta*, *Fair Rosamond*, *The Garland*, Climbing *Belle Siebreecht*, *Reine Olga de Wurtemberg*, *Polyantha grandiflora*, the small-flowered but exquisite *Polyantha simplex*, *Macrantha*, *Bardou Job*, *altaica*, *Paul's Single White*, *Carmino Pillar*, *Pezancea Briers*, *Celestial*, and *Maiden's Blush*, the *Dawson Rose*, *Leuchstern*, *Gloire de Dijon*—in fact, any vigorous kind that appeals to your taste. As to *Crimson Rambler* and other rambles on posts, this is the ideal position for them. Their beauty cannot be better displayed, provided always the soil is well prepared before planting. It would not do to just take out a spadeful of soil and put in the plants. You must take out a considerable amount of the soil, mix with it some well-decayed manure, then return again to the hole, leaving out just sufficient to enable you to place the roots about 7 inches or 8 inches beneath the surface. The turf can be returned again if this is desirable. You must take care to provide good substantial posts. Nothing is better than young Larch-trees with their lateral branches sawn off about 7 inches or 8 inches from the stem. Good stout Bamboo canes will do also. When the plants have attained a considerable height two stakes are then desirable, placed about 1 foot apart, and some stout spurs put to them to keep them steady. A cross-piece of wood tied on to the two stakes will keep them the better in position.

Rose Miss Glegg.—I read an article on old-fashioned climbing Roses in GARDENING ILLUSTRATED of December 13th, 1902, which gave me great pleasure. *Rose Miss Glegg* was exhibited last June at Southampton Rose Show, several standards of that variety being one mass of bloom. I think this Rose deserves larger cultivation. I know of a plant that has been in an old garden for over twenty years, and has produced flowers every season.—OLD ROSE LOVER, Southampton.

Roses in November.—Late in the season one may often gather a good many varieties in even better form than they frequently assume during the month of June, for, owing to a long continuance of mild, showery weather, Roses in general started into active growth in the autumn, and buds in various stages of development are still plentiful. *Gloire de Dijon* on walls or in the open is always one of the earliest as well as latest to give us some beautiful buds, while *Souvenir de Malmaison* is invariably of better form and colour as an autumnal than as a midsummer Rose.—J. G., Gosport.

Erratic flowering of Scotch and Austrian Brier Roses.—It really looks as though a perpetual race could be evolved by careful crossing. I have always thought it strange that no additions have been made to the Perpetual Scotch Rose known as *Stanwell Perpetual*. This variety remains alone, yet a few more as good and of other colours would be welcomed. The introduction of *Soleil d'Or* shows it is possible to have autumnal flowers of the Persian Yellow type, so that perhaps a similar character could be given to the pretty little Scotch Roses, and I am sure if we had an autumnal-blooming *Harrison* it would be of much value, not merely for its wonderful hardiness, but also for its lovely diminutive form and

FERNS.

NOTES AND REPLIES.

Adiantum Farleyense in hanging baskets.—At Bicton, in a lean-to house, facing north, I saw this used with fine effect as a hanging plant, a purpose I have not seen used for before. Several plants hung from the roof. These were in 6-inch and 7-inch pots, and so vigorous were they that the fronds hung over, completely covering the pots. Undarnesth, on the bed, was a fine lot of Ferns of many kinds, mixed with the showy Impatiens Sultoni and fine plants of Cypripedium Harrisianum.—C.

Nephrolepis exaltata.—This is one of the most valuable of Ferns for amateurs who have little artificial heat. It is equally good as a pot plant or for hanging-baskets—in fact, for the latter purpose it has very few rivals, for while its tall fronds fill the central portions of the basket, the older fronds droop down over the edges, and after they get well established the base of the basket is completely hidden by combs that give a very pretty effect when seen from below.—J. G., Gosport.

Growing the Killarney Fern (*Trichomanes adianthifolium*).—I should be grateful for any information about ways for growing Filmy Ferns. Those I have seen are

excellent base on which to allow the rhizomes to ramble.]

—A month or two ago I noticed that a question was asked in this paper as to how this Fern should be grown. The answer gave the usual treatment. I now wish to suggest treatment which I have tried and found successful. This method is vastly preferable to that of enclosing it in a dark glass case, where its beauty can only be seen when the glass structure is removed. I was recently given a piece of this Fern, which had grown in a structure of the above description for the last twenty or thirty years. I planted it in the approved material in an Orchid-pan, and stood it on the floor of my greenhouse in such a way as to be well shaded from the strong light, as the house faces south. Immediately alongside and at a higher elevation I have placed a large earthenware basin, which is kept quite full of water, and over this is suspended a hose-pipe connected with the water supply, and the water is allowed to drip slightly: the drop coming into contact with the water surface below causes a fine spray to disperse all round to a distance of a foot or so. This keeps the fronds of the *Trichomanes* in a nice damp state, and produces in an artificial way the conditions in which it grows in the wild state near dripping

very coldest localities, when the hexagon netting is the better. That cold winds are the chief cause of the curled leafage I had ample proof in these gardens last spring in the case of two young trees trained on a west wall. Owing to an oversight on my part no protection was afforded. As in "G. H. N.'s" case, the young foliage looked the picture of health for a few weeks, but after a time all the leaves got more or less affected, and in time dropped off, and the trees looked very bad. I am not sure now whether one will ever make a tree. On the other hand, a tree of Gladstone was left unprotected on a south wall, and here and there a leaf was blistered, while on the Peach wall proper, sixty yards long and facing due east, not more than a score of leaves was affected. These trees were protected with a double thickness of 3-inch mesh netting, which was put up March 15th, the glass coping being put on a week earlier. The nets were taken down May 15th, and the glass coping taken away the first week in June. If "G. H. N." takes similar precautions it seems difficult to account for the sorry plight his trees get into year after year. On a small scale the affected leaves may be picked off, but it worries the gardener not a little when all more or less follow suit and his most promising crop is a failure. A suggested preventive is to spray the trees with a solution made by dissolving 1½ oz. of carbonate of copper in a quart of liquid ammonia, diluted with 90 quarts of water, once before the buds unfold, and once or twice after the fruit is set. I have not used it myself, so cannot say if it really does prevent the blister. As before stated, I have always found that the gradual removal of the affected leaves is the best remedy, except last spring on the two trees on the west wall. This was owing, I consider, to the exceptionally cold spring we had. Your correspondent should try this latter remedy on its first appearance and persevere with it, unless a sure preventive is forthcoming in these pages.

EAST DEVON.

APPLE GASCOIGNE'S SCARLET.

THIS, as its name implies, is a handsome, rich coloured fruit, and suitable for either dessert or kitchen. It is a most prolific bearer on the Paradise stock. Avoid too close pruning, and the crop will be right. I have it as a standard in the orchard, and though the tree is small as yet, it had a nice crop the past season. Should the tree under garden culture make too much wood, root-pruning is preferable to using the knife too freely, and this advice stands good in the culture of all fruits. This Apple is seen to advantage in Kent, and in colour is much like Baumann's Red Rainette.

J. M. B.

GLASSHOUSES FOR MARKET GROWER.

I HAVE bought a shop with some ground attached, and think of putting up a glasshouse about 70 feet long, parted in two, one for Cucumbers, the other for Tomatoes. I would like a little advice as to the best description of house, most economical boiler (would like it large enough to heat another house if required later), quantity of piping? I have thought of a span-roof with path down centre and beds on each side. Would it be possible to have it so as to force Rhubarb, Seakale, etc., under the beds? I would like some suggestions as to crops to succeed Tomatoes and Cucumbers? What should be next of the house complete put up by builders? I am a gardener, but have had no experience in growing for market.—SOMERSET.

[Had you given us some idea of the size of the piece of ground attached to the shop it would have helped us materially. One house 70 feet long, cut in two to suit two crops, means that you have nothing for market at any time, for you cannot do much in a house 35 feet long; less, indeed, if you wish for a house so narrow that the path is to run through the centre. The best style of market house is one 20 feet wide, and you must bear in mind that a less high wall carries a house of this size than in the case of a house only 10 feet wide. Such a house would contain two side beds and a larger and wider central bed. Or you could erect a double-roofed structure on one set of ground walls, with a central wide plank in the middle to act as gutter. This, perhaps, would be your best plan. In such a structure the outside walls would require to be 3 feet high out of ground; walls 4 inches thick with 9 inch piers in

Apple Gascoigne's Scarlet.

the miniature greenhouses and stand in windows. I believe they are called "Wardian cases." I have a beautiful Killarney Fern, which needs more room than it can have under a large bell-glass.—E. M. I. R.

[All this requires for growing successfully in the dwelling-house is a close glass case in which a sufficient quantity of moisture can permanently be afforded, attention in keeping the sun's rays from it, and in supplying it with the necessary amount of water at the roots. Moisture this Fern must have, as the delicate fronds if exposed to drought or the effects of sunlight for even a very short time would completely shrivel up. Heat is equally disastrous. We have known plants of this species that were for a whole fortnight frozen into a solid block of ice, and when under the influence of the thaw the fronds gradually recovered their former positions, these plants had not suffered from the rigours of the temperature to which they had been exposed. The Killarney Fern is provided with rhizomes or stems of a woolly nature, which trail on the ground and which possess a very strongly-marked power of adhesion. This species thrives best when the rhizomes are in close proximity to a stone of a porous nature, such as sandstone, to which they will cling with great tenacity. When stone is used it is necessary that a little peat of a sandy fibrous nature should be placed at its base to establish the plant. Small pieces of fibrous peat, charcoal, and crocks form an

caves and waterfalls. Under these conditions the Fern is doing well and has made many new fronds. The simplicity of this arrangement is such that anyone can try it, and a barrel or tank overhead would supply the necessary drip should the premises not be connected with a regular supply. The Filmy Ferns are a very interesting group of plants to grow.—I. R. G.

FRUIT.

BLISTER OR CURL IN PEACHES.

THIS is caused by a fungus (*Exoascus deformans*), and is much more in evidence after cold, cutting winds and severe frosts, therefore we must still conclude it is these two evils that cause it, and no pains should be spared in early spring to prevent its appearance, which is best done by protecting the tender growths with hexagon or other similar material, erecting this before the flowers unfold, and keeping on until general weather sets in. When this kind of protection is used some means must be devised to roll it up on mild, sunny days, but no harm will ensue if it is kept down on cold, boisterous days or when below freezing point. It seems somewhat puzzling to account for this in "G. H. N.'s" case (p. 548), as he appears to have taken every precaution. Usually a double thickness of 3-inch mesh netting affords ample protection for this fruit, except in the

each 10-foot run of wall. The central gutter would be supported on 9-inch brick piers. We suggest this type of house as you wish to grow things under the stages, and only in this way is the space available. In this kind of house the staging may consist of inch iron barrel, on which the wood crossbearers rest, those at the outside walls being let into the brickwork. Wood crossbearers are made of quartering 3 by 2 $\frac{1}{2}$, and on the underside, set 6 inches back from front line, a hole is sunk with centre bit to receive the inch iron barrel forming the upright. These uprights occur at every 9 feet or so. The covering for stage is of galvanised iron sheets, and the whole constitutes one of the simplest and cheapest stagings, and is well-nigh indestructible, as so little woodwork is exposed to moisture. The iron uprights are set on a pier of bricks, fixed in concrete, and sunk in the ground 6 inches. Wood uprights would be cheaper, of course. Fourrows of 4-inch piping would be required to each house, and about 12 feet wide outside would be suitable. If we had a choice in the matter, we should prefer the wide house first stated, with a dark shed erected elsewhere for Mushroom growing and for forcing Seakale, Rhubarb, etc. As to cost, either the wide or compound structure would differ but little at the finish. But a better way than employing builders, if you can arrange the details of the structure yourself, would be to employ a bricklayer to do the brickwork for so much, and a carpenter for the woodwork, which can all be purchased ready for fixing. The hot-water work also should be done in like manner. Of course, if you cannot arrange the work it will cost you more. With no knowledge of the cost of material in your district, we give as an average rate for a market house of say 20 feet wide, heated, about 30s. per foot run. A good, reliable boiler is the horizontal tubular, which is easily repaired in sections when occasion arises. Some good crops to follow those named by you would be Tuberoses, bulbs in variety, Solanums in pots, Chrysanthemums, and Ferns for cutting.]

NOTES AND REPLIES.

Highly-coloured early Apples.—Kindly mention a few of the very earliest eating Apples that are a good red colour? Only mention those that you can really recommend, please, as I am very anxious to have a few really good ones.—NORMAN.

Wood highly-coloured early Apples are Worcester Pearmain, Lady Sudeley, Devonshire Quarrenden, Joan-ting, Beauty of Bath, Duchess of Gloucester, and Red Astrachan.]

Pear Winter Nelis.—This season, when Pears are none too plentiful, Winter Nelis, though ripening a little earlier than usual, has proved valuable for filling up what would otherwise have been a gap in the supply. The fruits are rather small, but the flavour is excellent, as is usually the case with this fine old sort, and therefore much appreciated for the dessert. The trees from which the fruits were gathered are old and diagonally trained, and were partially spur pruned last winter. In warm districts Winter Nelis will succeed as a standard, pyramid, or bush, but on cold soils should always have the protection afforded by a wall. Grafted on the Quince-stock it bears well as a cordon, and the fruit also then comes larger.—A. W.

Late Apple and Pears.—I shall be much obliged if you will kindly, through the medium of your valuable paper, give me the names of (1) Four good late Pears for use about Christmas time; (2) Four good cooking Apples for use during the winter; (3) Two good cooking Cherries? The soil here is about 2 feet deep, rather heavy, and the subsoil chalk. The situation is high and exposed.—L.V.

[As you do not state how you wish to grow the trees, we give below a list suitable for all purposes for you to select from. Four wall Pears, to come in about Christmas: 1, Bourri-d'Anjou; 2, Winter Nelis; 3, Beurré de Jonghe or Nouvelle Fulvie; 4, Glout Moreau. Four bush or pyramid Pears: 1, Hynshe's Prince of Wales; 2, Winter Nelis; 3, Beurré d'Areberg; 4, Josephine de Malines. Four Pears as standards: 1, Winter Nelis; 2, Knight's Mouarch; 3, Beurré d'Areberg; 4, Josephine de Malines. Four good cooking Apples for winter use, as bushes or pyramids, are: 1, Beauty of Kent; 2, New Northern Greening; 3, Lane's Prince Albert; 4, Alfriston. Four Apples as standards: 1, Beauty of Kent or Kent's Filbert; 2, Golden Wonder

3, Belle de Pontoise; 4, Newton Wonder or Wellington. Two good cooking Cherries are Morallo and Kentish Red, which succeed equally well either as wall, bush, or standard trees.]

GARDEN WORK.

Conservatory.—There are still a few late Chrysanthemums, which are very useful for cutting. Some of the very late sorts have not done so well this season, especially if stopped late, as the wood has not ripened. We have some plants now in bud—white and yellow. The flowers will not be large, but will nevertheless be useful. Daffodils are now coming in, and Roman Hyacinths have been plentiful for a long time. We find Cyclamens very useful for filling specimen glasses. Sometimes we use their own foliage, but it is rather too large and stiff. Small sprays of the scented-leaved Geraniums are very useful for this work, and if a few plants are planted in the border of the conservatory they will grow against a wall and supply foliage for picking all winter for a change. The Indian Daphnes are very sweet, but it is not over one who succeeds with them. I have had them do well in yellow loam, with a little leaf-mould and sand, and a little crushed charcoal placed in the bottom of the pots as drainage. The finest plants I have ever seen were growing in a bed of loam, peat, and sand, peat predominating, in a light conservatory. One reason why these plants look so thin of growth is that the ladies will cut off every bit of flower the plant produces, and, of course, with each cluster of blossoms go both wood and foliage, this weakening the plants. The only remedy for this, if the flowers must be cut, is to plant a few out, or if grown in pots, to have them in larger numbers. They may be propagated from cuttings of half-ripe wood under a bell-glass, and kept cool till callused, and then moved to a little warmth, or they may be grafted on the Mezereon or the Spurge Laurel. Cuttings of Chrysanthemums should be taken from time to time as strong ground shoots or suckers are produced. Where only a few plants are wanted, they may be struck in single pots, but for wholesale work shallow boxes filled with sandy soil are suitable. The cuttings must be potted off as soon as rooted. It is hardly necessary to save all the exhausted plants as they come from the conservatory, especially of such soft-wooded things as Salvia and Begonias, as if the cuttings are struck early and grown on freely, the young plants will be better than old out-down stuff for next season. Give ventilation freely in mild weather, but keep out cold winds.

Forcing-house.—Where there is plenty of forcing material, in the shape of plants established in pots, and one or two good warm-houses, there will be no difficulty in obtaining plenty of flowering plants for the conservatory and also for cutting. For cutting there is nothing just now superior to Lily of the Valley, Roman and Italian Hyacinths. I like the Italian at this season better than the Roman. They produce more spikes, and the spikes are longer and the flowers keep well. The bulbs are cheap, and this year they are very fine, whilst the Romans are very inferior. A year or two ago I purchased better bulbs in the wholesale market at 60s. per thousand than could be obtained for 90s. this season. Paper-white Narcissi are cheap enough, and force easily, but the flowers from the South of France are so cheap that very few grow them now. It is not easy to have too many of the bright, showy single and double Narcissi where cut flowers are in demand. Bulbs that were potted in August will now be in flower, and, if started in boxes, the bulbs can be lifted out as they come into bloom and used to fill bowls or any other purpose, simply filling in the bowl with damp Moss. Tulips can be used in the same way; but these should be brought on under the stage till the stems have been lengthened out a bit, and then moved to a cooler house. Especially is this necessary if the flowers are required for cutting, where long stems are necessary. The forcing house should be kept constantly filled up with plants from another house with a lower temperature. The temperature of the forcing house will be

regulated by the demand, and in some measure also by the crops coming on. As a rule, it is not generally necessary to have a higher night temperature than 60 degs., but if there are two houses used for forcing, one may be a little in advance of the other. Rhododendrons, Kalmias, Azaleas, both Indian and others, Lilacs, Prunus triloba, standard and bush Roses, Dutzias, in fact, all hardy shrubs which have been well grown and ripened, will force. One of the best forcing shrubs is Weigela rosea, but it should not be rushed in a high temperature, and the flowers are useful for cutting. I remember when this plant was first introduced I grew it under glass, and it made very handsome specimens; in fact, I have never seen it so good outside as I had it then in pots. The water-pot and the syringe must be used with judgment, and as much fresh air admitted on bright days as can be done without unduly lowering the temperature. Close early in the afternoon.

Early Grapes.—Keep the atmosphere drier when the Vines are in bloom. Black Hamburg and Foster's Seedling usually set freely if the atmospheric conditions are suitable. When the pollen is ready for distribution, a tap on each cane with a padded stick, or even with the hand, will scatter the pollen when it is ripe. I have generally found these simple means sufficient, but sometimes a camel's-hair brush is used, or a long-stemmed inflorescence of the Pampas Grass lightly passed over the plants will suffice. Sub-laterals should be stopped to one leaf, and the berries should be thinned as soon as they are large enough to show which are likely to take the lead. This is important, as the berry which obtains an early lead always keeps it. Temperature 55 degs. at night, falling to 60 degs. at sunrise; air to be given in very small quantities at 75 degs. to 80 degs.; closing early enough in the afternoon to run the thermometer up to 85 degs. or even 90 degs. will do no harm. This will save fuel, and cause the bunches to spread out.

Figs in pots.—These may be grown in any house where either a forcing or a more moderate temperature is maintained; but there should be no fluctuation. The work should go on steadily from the first, not treated to a high temperature for a few weeks, then dropped down to 50 degs. or less. Fifty degs. at night is a good starting figure, but as the growth proceeds the temperature should advance till 65 degs. is reached. Figs in pots have been grown in a Pine stove, and in almost any kind of forcing-house, with more or less success. Of course, they are best in a house by themselves, but this cannot always be given to them. Figs should never be watered with cold water, and, after the fruits are fairly swelling, liquid manure may be given freely. Figs will succeed under pretty well the same conditions as Grapes; in fact, good crops have been grown under Vines in pots, and also planted out on the back wall, or trained up the sides of the house.

Window garden.—The chief flowers now will be bulbs, Cyclamens, and Primulas. The other day I saw a well-grown plant of Cypripedium insigne in flower in a window, and the plant had been so grown for some years, being moved in summer to a cool-frame in the garden.

Outdoor garden.—Those who do not see Sweet Peas in autumn may sow a few seeds very thinly in pots in a cool-house to plant out when the weather is suitable in March. Sweet Peas transplant very well. Bush Roses should have a little dry mellow earth placed round the stems when frost comes, or before. For clothing a steep bank there is nothing equal to the Wichuriana Roses. The newer forms are improvements on the type. One of the best is Jersey Beauty. During autumn and winter the scarlet fruits stand up above the glossy foliage, and are very attractive. The plants grow rapidly, and their propagation is easily effected by cuttings or layers. The latter method is very easily accomplished as the branches creep along the ground. After frost all small or recently-planted things should be examined and the soil pressed firmly around the stems. During open weather planting can be carried on, and all kinds of earthwork, such as the formation of rockeries and clearing sites for Ferns, or any other

special feature which it may be desirable to create. Before planting creepers to cover the stems of trees, the soil close to the trees should be improved to give the plants a start. If Roses are planted, select the most vigorous climbing or Rambler for the purpose. Caroline Pillar does well in such positions.

Fruit garden.—All fruit houses should be thoroughly cleaned before the buds have the least inclination to start. This is doubly necessary where there has been red-spider or mildew during the past season. Mealy-bug again is a terrible pest in a vinery, and where Vines are infested a strong effort should be made to clear it out, and when everything in the house has been thoroughly cleansed with soap-and-water and hot lime wash and sulphur, and the surface of the border renewed, a close watch must be kept upon the Vines all through next summer for stray insects. At least, such has been my experience. I am satisfied that mealy-bug can be cleared out in one season if a strong effort is made, but stove plants must be kept out of the vinery. Mildew is very often caused by dryness at the root, and in very bad cases one of the first things to be done should be to examine the condition of the borders. It often happens when an insidile border has been permitted to get dust-dry that the water will not penetrate the dry spot till the soil has been broken up, and where the roots have been lifted and made comfortable, the mildew may be more easily combated and driven out. It is not often there is any spare liquid-mannure, unless one has access to a farmyard tank, but if there is it may be profitably utilised among fruit-trees and bushes which are well laden with fruit. A good way of doing this is to make holes with a crowbar to receive the liquid.

Vegetable garden.—Most of the seed lists are now in, and if not already done seed orders should be made out and sent in. If any old seeds are left over from last year it will be a very easy matter to test them by sowing a hundred seeds or so of each kind in pots, and counting the percentage of growth. Last season was not a good ripening season, and many of the new seeds were not got in in good condition, and the price will be a little higher, and I notice some seedsmen recommend the seeds to be sown a little thicker. As a rule, many sow the seeds too thickly, and not only waste the seeds, but, unless thinned in good time, injure the crop. But, under any circumstances, it is a mistake to sow seeds which have been tested too thickly, as even if thinned promptly the plants are more or less weakened from overcrowding. The early borders should be forked over again, and made ready for cropping. If very fine Onions are wanted, sow a box or two of seeds now and place in heat, and hards off for planting out on well-manured ground in April. This is a good plan for anyone who has been troubled with the Onion-maggot, or whose a few very fine Onions are wanted for exhibition. Cauliflowers, both early and late, may be sown now in heat to follow the autumn-sown crop, or to supplement the latter should any failures occur. Continue to make up hot-beds for Potatoes, Carrots, Radishes, Lettuce, &c. E. HUDNAY.

THE COMING WEEK'S WORK.

Extracts from a Garden Diary.

January 10th.—We have commenced potting off young cuttings rooted in autumn, and shall give them a little heat to start them, and in March, or as soon as the weather is safe, they will be moved to cool-pits and frames. This will give room in houses for potting off the spring rooted cuttings, which will require attention. All plants from which cuttings are wanted are now receiving more warmth to hasten the growth and produce cuttings abundantly. Sowed more Tomato and Cucumber seeds in warm-pits.

January 10th.—Unmilled Peaches on walls ready for pruning and cleaning. We have been overhauling seed Potatoes, and some of the early kinds have been placed in trays as far as the trays permitted, the remainder being laid thinly on the floor of a stable not at present in use, where they will be safe from frost. Planted more French Beans in 8 inch pots for forcing. Space is left in the pot for earthing up; only four Beans are placed in each.

use this size because it is a convenient one for the shelves. We generally plant No Plus Ultra for first crop, and then Canadian Wonder.

January 21st.—Sowed more Mignouette for blooming in pots. Planted cuttings of Honey-suckles, Jasmines, Ivies, etc. Planted the last lot of Briers for hudding, and mulched with stable-mannure. Rearranged conservatories, and filled vacant places with plants from forcing-houses. Baskets filled with Begonias are still very bright. Bushy plants of Gloire de St. Reine are excellent for this work, the base of the basket being covered with creeping plants. *Viola elegantissima* is useful for this work in winter. Shifted on Ivy Geraniums, and moved to warm-house for early flowering.

January 22nd.—Planted a few early Potatoes in a border in front of a forcing-house. This bed comes in before the frame Potatoes are all finished. They will be sheltered if frost comes. This is done by hooping the bed over with long Ash or Hazel rods tied together, and when frost is expected the bed is covered with frigidomo. The borders in front of the house are very useful for other early crops, such as Cauliflowers, Carrots, Lettuces, Radishes, etc., and later crops of early things will be planted early next month on the borders in front of a south wall. Put in a lot of Vine-eyes in sods of turf on pipes in early vinery.

January 23rd.—Relays of Strawberry plants are placed in warm-house every fortnight, so that there may be no break in the supply. All vacant land is dug or trenched as soon as possible after the crops are cleared. The arrangement of the season's cropping has been marked on a plan. This, in fact, was done before the land was manured to avoid mistakes, as land for tap-rooted plants is not manured now. All shrubby borders are being forked over lightly, as Snowdrops and Aconites are now visible.

January 24th.—Moved more Rhubarb and Siskale to Mushroom-house. A few roots of Chicory have also been potted and placed in the dark. Mushrooms are fairly plentiful now. The best way to ensure a constant supply is to keep all bed spaces filled up, and then if one bed does only moderately there is another close behind it that will compensate us; at least, I have found it so. Plenty of white, crisp Siskale will be appreciated now, and there is never likely to be too much Asparagus. Broccoli turning in will require watching now.

BIRDS.

Two dead Canaries (*Mica Du Lincolne*). Both these birds were very thin, and had evidently been ailing for some time. The internal organs were in a very diseased state, the immediate cause of death appearing to be consumption of the bowels, which may be attributed to the effects of a severe chill or unsuitable food. No particulars are furnished as to diet and general treatment of the birds. Many of the bird seed mixtures as sold in packets contain Inga, and this seed if partaken of in any quantity is very injurious, containing as it does much oil, and an active principle (ingaline) which is poisonous. The staple diet should be Canary-seed. Other seeds should be added, such as Rape, the best being the smaller kind, which is of a purple or reddish hue. This, being cooling, may be given with safety. A little white Millet-seed may be given occasionally, while Linseed is very useful in helping these birds over their moulting—indeed, a little may be given at any time. Hemp-seed should be used sparingly, as it is of a very fattening nature. The small kind of Hemp, of a bright grey colour, is the best. The green food may consist of Groundsel, Chickweed, Dandelion, and Lettuce, but should be given in small quantities, and fresh, although not immediately after gathering. Any not consumed within a couple of hours or so should be removed from the cage, stale green food being injurious. A piece of cuttlefish-bone placed between the wires of the cage for birds to nibble at tends to keep them in good health. The old-fashioned plan of putting a rusty nail in the drinking water is very good, as thereby a mild tonic is provided. It would be desirable to regulate the diet of your

remaining bird. Put it on plain food, giving a little fresh bread-and-milk occasionally, but on no account sweets of any kind.—S. S. G.

POULTRY.

Turkeys laying in the winter.—I have two hens (last year's birds). They each brought up a brood of young ones, and they both started laying again about the middle of October, and have continued (with one and then a days interval) ever since, and I had up to December 8th 82 eggs. Is not this very unusual?—F. E. Dymchurch.

Death of Orpington Cock (*Esquiver*).—There was a large collection of fluid in the cavities of the body of this bird. This complaint, known as ascites, or abdominal dropsy, according to the situation occupied, is of rare occurrence among poultry, and, as it generally arises from a diseased state of the internal organs, it is incurable. It would be well to change the diet of your fowls, as a constant use of Indian Corn is sure to bring about disease. A warm meal in the morning is the right thing—during winter, especially—but to give Indian Corn as a second meal, day after day, is altogether wrong. This should be discontinued, or very much reduced in quantity, and good, sound Barley, Wheat, or Buckwheat substituted, and given in turns. A frequent change of food is much to be recommended, being far better than the constant use of one kind of grain. The more exercise your fowls can get the better will be their health. If they are not on a Grass-run, supply them with plenty of vegetables, both raw and cooked.—S. S. G.

AQUARIA.

Plants for fish-pond.—I shall be obliged if you can tell me the name of some aquatic plant for a fish-pond about 1 foot deep, with instructions how and when to plant? The pond gets a fair amount of light, but no sunshine. The fernery in which the pond is kept at 50 degs. to 55 degs. in winter. The water is rather hard. The fish die after a few months, which I think is from want of a plant. They are fed on varmicelli.—E. S.

[You will find your fish will be more healthy if the pond is furnished with a few aquatic plants, but no fish will live long in hard water. Clear pond water or river water should be supplied. The bottom of the pond should be covered with about an inch of coarse sand, well washed to remove all impurities; upon this should be placed a thin layer of shingle or coarse gravel. There should be added the aquatic plants, such as the Water Crowfoot, the Water Milfoil, the Anacharis. To start these they only require a stone to be tied to the roots, and some sand added to keep them in position. It would be well to introduce a few water snails to your pond, as some species of these feed upon the green growth that collects upon the sides of the pond and upon decayed vegetable matter, and are consequently very serviceable in keeping all clean and bright, while their eggs and fry provide the fish with food. It is well to be careful in the selection of these, as some of them will consume the healthy growing plants. A very suitable species is *Planorbis cornus*, the shell of which is flat-coiled in shape, of a dark reddish brown colour, sometimes almost black, and about an inch in diameter. It is to be found in slow-running or stagnant water.—S. S. G.]

LAW AND CUSTOM.

A gardener's claim for compensation.—I have taken a house and garden on a lease for five years. The garden is in a very neglected state, not having been cultivated for two years. If I improve the place can I claim compensation on quitting? I propose to erect a lean-to greenhouse against one of the walls, and grow plants in it to sell. I can't remove it on the expiration of my lease? What kind of heating apparatus could I put in which would be removable?—CANNON.

[If in the lease the place is described as a market garden, or if the lease permits you to cultivate the place as a market garden, you may on quitting claim compensation for the greenhouse and heating apparatus, but your right to remove it would be doubtful. If the lease does not describe the place as a market garden and contains no provision for cultivation as a market garden, you may on quitting remove the greenhouse and heating apparatus as trade fixtures, although you could not claim compensation for them. You could not, on quitting, claim compensation for "general improvement" of the garden.—K. C. T.]

CORRESPONDENCE.

Questions.—Queries and answers are inserted in GARDENING free of charge if correspondents follow these rules: All communications should be clearly and concisely written on one side of the paper only, and addressed to the EDITOR OF GARDENING, 17, FURNIVAL-STREET, HOLBORN, LONDON, E.C. Letters on business should be sent to the PUBLISHER. The name and address of the sender are required in addition to any designation he may desire to be used in the paper. When more than one query is sent, each should be on a separate piece of paper, and not more than three queries should be sent at a time. Correspondents should bear in mind that, as GARDENING has to be sent to press some time in advance of date, queries cannot always be replied to in the issue immediately following the receipt of their communication. We do not reply to queries by post.

Naming fruit.—Readers who desire our help in naming fruit should bear in mind that several specimens in different stages of colour and size of the same kind greatly assist in its determination. We have received from several correspondents single specimens of fruits for naming, these in many cases being unripe and otherwise poor. The difference between varieties of fruits are, in many cases, so trifling that it is necessary that three specimens of each kind should be sent. We can undertake to name only four varieties at a time, and these only when the above directions are observed.

PLANTS AND FLOWERS.

Fungus in soil (F. Goodchild).—The sample of soil that you send is badly infested with the spawn of some fungus that lives on decaying vegetable matter. It probably originated from some decaying wood which was infested by the fungus. We would advise you to clear it out and substitute some fresh loamy material, over this placing a inch of some rotten manure to encourage the growth of the roots.

Old stools of Chrysanthemums (F.).—Yes; the old stools of Chrysanthemums are available; but they are never so satisfactory as newly-struck plants. In old plants you will get only crowded and small, inferior blossoms, whereas newly-struck cuttings produce large flowers and healthy plants. The shoots throw up from the roots of your compound are available for striking at any time between now and March.

Pellaea adiantoides (R. H. P.).—Your specimen was very badly attacked with thrips, which cause the withering and curling of the fronds. Vaporising with the XI. vaporiser will kill them without injuring the young growth. The atmosphere of your greenhouse is undoubtedly too dry for this Fern, which accounts for the insect pest making such headway. We should certainly recommend you to try removing it into your cooler structure, where your troubles with it will probably vanish.

Lithospermum purpureo-ceruleum (Rockery).—The Lithospermum may be cut down to the ground at once, and could have been so treated in October or even earlier. It is a true perennial, producing annually its stems and blossoms, the former decaying when flowering is completed. Fresh shoots in a tuft appear at the base. Beyond a mulching of calcareous soil each year firmly placed about the base, the plant requires no further special care. This may be done when flowering is past. The central crown tuft should not be so covered.

Relaying Box (Coila).—It often happens that box is neglected and not kept hard clipped, the result being that it gets tall and ragged. Trim back from the edge all the gravel some 12 inches wide, then take the Box away and lay it in by the roots. Fork up the ground where it grew, adding some fresh soil and manure. Strike a line, chop down a straight furrow some 6 inches deep, have the box, if very lanky, hard trimmed, tops and roots, to about 7 inches, retaining some of the roots, then plant it thinly and evenly so as to form a perfect edge. Put back the soil against it, tend firmly, and then replace the gravel.

Bulbs in pots (F.).—Daffodils and Tulips put into pots and stood outdoors, covered up with ashes, should there remain until the crowns have thrown up quite an inch and the pots are found to be fairly full of roots. Then you can take them into a greenhouse or frame, either at intervals, as you may want to bring them on, or all at once. Do not subject them to heat, if you propose to do so, directly; rather do it gradually. The time of blooming will materially depend on the warmth given, but if the house or frame be cool, your bulbs will not bloom for some time. Keep them near the glass, or the leaves will be drawn.

Chrysanthemum blooms damping in centre (F.).—The cause of your blooms falling to open in the centre, and afterwards damping, is, we should think, probably due to the low temperature maintained in your greenhouse. The Japanese flowers more particularly need a temperature of about 50 degs. to develop satisfactorily, and if the weather be damp and foggy, and a free circulation of air through the greenhouse be not allowed, the blooms are very likely to damp off in the manner you describe. Again, drip from the roof will sometimes fall on the blooms, and this in a very short time will render them useless.

Cocoa-nut-fibre (Rockery).—The Cocoa-nut-fibre sent is the ordinary fibre refuse obtainable. The longer fibre is used for manufacturing purposes. If you wish for a coarse sample, your best plan will be to sift what you have and retain the rough. By using a quite fine sieve and getting rid of all the fine dust, you would have a useful article in the residue. We think if you mix the ordinary fibre, such as you have, with an equal amount of rather dry, fibrous turf, and a similar quantity of old mortar passed through a 1/2-inch sieve, mixing the whole together, you would have an excellent mulch for your rock plants. The material should be firmly piced around the tuft as a mulch, and not upon the tuft of leaves.

Roses for low fence (Beginner).—Seeing that there is a bank near your fence, you could plant nothing more suitable than the charming Wichuriana Roses. These would quickly cover the hurdles and trail over the other side and down the bank, suppressing the latter's upon your premises. Six best varieties are: Early Beauty, Gardening Illustrated Rose, Frigate, King of

Wichuriana rubra, and René Andre. They will outflower a second time in the same year, but they make ample amends for this in the rich protuberance of their glistening foliage, which is almost evergreen. Should you, however, desire Roses that bloom in autumn as well as summer, Cheshunt Hybrid, Ames Vibert, W. A. Richardson, Ulrich Brunner, Conrad F. Meyer, and Longworth Rambler would be very suitable.

Asparagus plumosus from seed (Coila).—Fresh seed of this will germinate freely in a good hot-bed in the spring. The best soil in which to sow it is sandy peat, which must be kept constantly but moderately moist. As soon as you can handle the seedlings, prick them out singly into small pots, using sandy peat and leaf-mould, returning them to a moderate hot-bed until they are well established and growing freely. This Asparagus does best in the warm, mainly shaded part of a cool stove or intermediate house, lightly shading it from hot sun. If you have any old plants and wish to increase your stock, you can do so by division. A crown or two with a few roots attached will soon make a strong plant in a warm-house. It also does well in an unheated greenhouse during the summer.

Rose cuttings striking in water (F. E.).—Such cuttings as have roots as you describe would be best potted off into thumb pots in a sandy compost, taking care that no manure is present in the compost. Place the cuttings when potted under a bell-glass or a small frame constructed with four panes of glass. Remove the glass each day for a few minutes, and wipe off any moisture condensed thereon. From this small pot repeat into next size when roots are freely formed, and then plant out in the open in May if weather is genial. If, of course, you need not keep the potted cuttings under the glass more than about two or three weeks, but they should be placed on a shelf near the glass. Although they must not be allowed to become dry at the roots, very little water will be required. Spraying over with a fine sprayer on sunny mornings will supply them with as much water as they require for a considerable time.

Brugmansia arborea (F. C. Harvey).—It is quite natural for plants to lose all or nearly all its leaves during the winter, at which time it will not need much water, but enough must be given to keep the soil slightly moist. In order to flower it in a satisfactory manner, it will need a pot or tub from 15 inches to 18 inches in diameter, or even larger. Being a liberal feeder a mixture of two parts loam to one part of well decayed manure, with a little sand, will suit it well. Should the loam be of a heavy nature, a little leaf-mould may, in addition to the above, be mixed with it. It will be much better out-of-doors during the summer than under glass. Early in June it can without risk be stood out in a sunny spot. Of course, it will need attention in the matter of water, and as the pot gets full of roots a little liquid-manure occasionally is beneficial.

Campanula isophylla alba (Rockery).—The Campanula may be shorn of all its stems close to the crown tuft if you wish, but so doing you will not have the length of flowering stalk for another year, though the plant may flower freely enough from the crown growth. It is not in all districts, however, that the plant will survive the winter. It may do so in your case if protected from much wet. Any of the fresh green tips will root readily if made into cuttings of 2 inches long or less. Prick these bits or shoots when cut to a joint with a knife into pure sand or very sandy soil, placing the pots on the greenhouse shelf, and give one good watering and no more for a week. The system of constantly sprinkling such things overhead is often very bad. A good way is to get some clean pots well drained and three parts filled with sandy soil. Above this place some pure sand, and make firm. Prick the fresh green tips into the sand and treat as stated. Only the fresh tips are suitable; at least, these are much the best. Each one will make a good plant if grown on quickly after having been rooted.

Nephrrolepis (Rockery).—It is most likely the barrenness referred to is the result of over-dryness. This fern is a vigorous grower, making large quantities of root fibres, any such fibrous root-dryness would be detrimental to the well-being. Cleanliness of course is very desirable, and the mealy-bug should be kept in check. We do not, however, regard this as a primary cause. It is quite possible in the repotting of the plant the old ball of earth was not loosened sufficiently, and may even have not been wet enough at the time. It is best, when repotting old established plants of such things that a thorough soaking of the ball should be given, and the repotting done when the water had drained away. In this way the plant is sustained until new roots get away. If the plant is very bare and rough looking, the worst fronds may be cut out. Do not now keep the plant too wet, but in the growing season take care it does not suffer from lack of moisture. As the plants are infested with the bug, we would suggest cutting out and burning the worst fronds, or giving a mild fumigation. If this were done now and again before the new fronds appear, you may perhaps get rid of or reduce the mealy-bug, which in early spring increases at a tremendous rate. Sponging with soft-soap to which some paraffin has been added, mixing the whole with rain-water, would also be good. One tablespoon of soap dissolved in a quart of water and one dessertspoonful of the oil make a good mixture. A temperature rather warmer than that of ordinary greenhouse is best for this plant, say 55 degs. If tower than this keep the plant fairly dry.

TREES AND SHRUBS.

Plants for border (W. M. N.).—The following should answer your purpose: Esculus, Ametancher, Catalpa, Double Cherries, Cotoneaster, Crataegus, Halesii, Kalmia, Laurus, Magnolia, Malus, Mespilus, Pavia, Prunus, and Viburnum.

Pruning Rock Cistus (Rockery).—In respect to the Cistus, we are not sure from your description whether the plants referred to are Gum Cistus, i.e., Cistus proper, or Rock Cistus, so called—i.e., Helianthemum. If the variously coloured forms of the latter, prunings may be done now at any time, though we do not consider 8-inch plants to be in need of pruning at all. Old bushes of these when getting bare at the base are often freely clipped over with shears in October, when they break again from the stems, but they flower less well the next summer.

FRUIT.

Manuring fruit-trees (M.).—Only when fruit-trees are in a stunted, starved condition would it be justly the removing of 6 inches of the top soil over the trees for a radius of 3 feet from the stems, and adding 4 inches of stable-manure, re-covering with soil. If your trees were in fair growth previously there is danger that such manure-dressings may drive them into coarse, leafless wood-production, and render their latter state worse than the first.

Apples for Exmoor (M. G. Clark).—The following Apples should stand you in good stead: Cooking, Keswick Codlin, Lord Suffield, Potts Seedling, Eddingville, Tom Patt, Duchess of Oldenburg, Cox's Pomona, Frogmore Prolific, Warner's King, Golden Spice, Stirling Castle, Seaton House, Cellini Pippin, Lord Grosvenor, and Bismarck. Dessert: Mr. Gladstone, Irish Peach, Devonshire Quarrenden, Beauty of Bath, Lady Saxeley, Worcester Pearmain, Red Astrachan, Rivers' Early Peach, Brambling, James Grieve, and Cardinal. We would advise you to procure bush-trees on the Paradise-stock, planting 12 feet to 15 feet apart, and securing the trees to stout stakes the first few years or until established. Good early Peas are found in Heurre Giffard, William's Le Christieu, Louise Bonne of Jersey, and Heurre d'Amiens grafted on the tree stock.

Fruit-trees in small garden (A. M.).—As you long strip of garden ground which you propose to divide equally with a path down the centre runs north and south, you should plant your fruit-trees on the east side of the path, as then you will exclude but little sunshine from the western half. You may plant, say, six standard trees down the middle of the strip. These may be of Apples Cox's Orange Pippin, Stirling Castle, Duchess of Oldenburg, and Lane's Prince Albert, one Plum, Victoria, and one Damson. Partridge Peaches will be easy to get apart. On each side of these plant bush Apples, Peas on the Paradise or Quince-stocks, the Peas on the east side, and between you can have rows of Gooseberries, Currants, Raspberries, and Strawberries. Rows of these bushes may be 6 feet apart, Raspberries 4 feet, and Strawberries 3 feet. If you like, a row or two of bush Plum-trees may be planted instead of the dwarf kinds. Preferably fill one side with fruit, keeping the other half solely to vegetables.

Planting Logan Berry (Massachusetts).—If you get on your west wall a fair amount of sunshine, then as a reason why both the Logan Berry and the Japanese Wax-berry should not do very well against it. Both these Brambles like ample sunshine to ripen the growth and fairly holding soil. But you could hardly nail the best foreign shoots made each year to the wall, and it would be better if you could fix on its face a wire trellis 3 inches from the wall, the wires 9 inches apart, to which the long Bramble-like growths could be tied. Failing that, you would be better to plant 3 feet from the wall, and train the long shoots to tall, stout stakes, flatwise, like an espalier tree. When wood has cropped for a year or two, it is best to cut some of those portions out in the winter to make room for the strongest of the previous summer's shoots. Spur back to one bud any small side-shoots. Give mashes of manure in the summer. Three or four plants to be trained flatwise are ample for your length of wall.

SHORT REPLIES.

Lincolnshire Ltd.—Not a gardening query.—John Williams.—Quite impossible to say.—A. W. Child.—Any seedman will procure for you the Tomato you inquire about. You will also find it advertised in our column. See article on "Raising Tomatoes," in our issue of Nov. 23, p. 425. We do not reply to queries by post.—Analethe.—Kindly read our rules as to questions by correspondents.—F. Rich.—Not at all unusual. We have frequently figured such specimens.—R. E.—You will find an illustration with full description in our issue of Jan. 10.—R. H. R.—Kindly repeat your query.—P. I.—Your best plan will be to raise a bush from seed, and then you will get exactly what you want. No one grows such forms as you mention.—A. E. Spar.—The blue-tinted Gentians are not, we think, in cultivation.—Francis.—All depends on the size and condition of the bulbs. Bulbs are, as a rule, sold by the dozen.—W. Jenkins and Twenty Years' Reader.—Chrysanthemum Tuckwood White can be had of Mr. B. Tolmie, Tuckwood Farm, Norwich.—Fair Play.—The material I mention is of no value whatever for a lawn.

NAMES OF PLANTS AND FRUITS.

Names of plants.—W. W.—1, Yellow Beech; Gazania ringens; 2, Epiphyllum truncatum; 3, R. R. F.—1, Adiantum cucullatum Jacquin; 2, Adiantum hypoleucum; 3, Pellaea adiantoides.—G. Dunlop.—Arbutus Uvedalei; 2, Leucostaphyle formosa; 3, Cupressus thuyoides.

Names of fruits.—D. E. Prothero.—Eddon Pippin.—North.—1, Mère de Néage; 2, Not recognised.—G. Shepherd.—Kindly number each fruit. It is quite impossible to be certain to which fruit the figures refer when you put the numbers on the box.—Vis Eboracensis.—1, Wadhurst Pippin; 2, Sturmer Pippin; 3, Golden Greening; 4, Not recognised.—Ellen Bignard.—Ash's Farm's Pippin.

Book received.—"Chrysanthemums and How to Grow Them to Perfection," by E. H. Potter, F.R.H.S., Published by the British Fertiliser Co., 5, Cannon-street, Birkenhead.

FRUIT.

STRAWBERRY BEDS IN WINTER.

DETRIM: The winter months, especially after severe frosts and cold, drying east winds, the Strawberry-bed often bears a forlorn appearance when left in a natural state. A little surface cultivation may improve it, though in the case of old-established beds some judgment is necessary in dealing with the roots of the plants. Winter treatment differs according to the means and convenience of cultivators. Some like to see the manuring done early, others leave it until late in the season, and some apply no manure at all. The last certainly is not the course to be commended, because poverty of the soil is sure to set up mediocrity in the crop. Spring manuring may suit some land, while earlier applications are better for others. An open, gravelly soil is of necessity poor unless kept well fed, but it would be a waste of effort to be in great haste in applying manure to such land, because it is soon conveyed by rain to the drains or lower stratum of the soil. Manures, it will be seen, need to be given consistent with the nature of the soil to which they are applied. Heavy soil would be made colder and retentive of water by an early winter mulch, especially of cow-manure; the latter is better for light soils, and can be put on earlier, because of its compact nature it is transmitted to the soil more slowly than horse-manure. When this is put on in a fresh state, incorporated with strewy litter, it needs some length of time for it to become washed clean enough for the ripening fruit to rest upon. There is no doubt about the benefits following the application of cow-manure on poor or shallow soils, but there must be sufficient strawy matter in it to combine a fertilising manure and a protection for the fruit. In soil of ordinary quality horse-manure fresh from the stables is used to good purpose. The greater proportion there is of droppings the greater value they possess for the plants and the land. In the meantime, pending the winter mulch, the surface can be skimmed with the spade, when seedling weeds which may be present can be turned in. The ground should not be disturbed more than an inch in depth. This surface digging will be found useful in that it makes neat what has been an eyesore in the garden probably for some lengthened time. If artificial manures are employed, or a dressing of burnt refuse, wood-ashes, or soot is given, and it may be repeated these all have a value in adding fertility to the soil, they are each placed more easily within reach of the roots by adopting surface tillage. Deep digging, which I have sometimes seen in amateurs' Strawberry beds, is fatal to good crops, because by nature the Strawberry is surface rooting, and there certainly must be a loss if these are cut off by deep digging. When occasion requires it, Strawberry runners can be replanted early in the New Year with marked success, provided it is done with care, and every possible root preserved.

W. S.

CANKER IN APPLE-TREES.

TO THE EDITOR OF "GARDENING ILLUSTRATED."

SIR,—In your issue of January 10th there is a very interesting article on "American blight in fruit-trees." Is this pest the same as that known as canker? Again, in your issue of July 5th, 1902, there was a letter signed "G. D. Hunt," giving a remedy for canker. He stated it consisted in painting the affected part with a paste made of clay mixed with chlorydric acid. I wrote to a droggist ordering some of the acid, and I received the reply: "Yours received, but as we take it chlorydric acid would be hydrochloric acid, which we have heard of being used for this purpose—viz., disease in Apple-trees—we could not, of course, post any, as it is an article not sent in this way, in addition to which, of course, it must not be used concentrated, but would have to be diluted several times, otherwise it would damage the trees." Would Mr. Hunt, or some of your other correspondents, kindly say is this hydrochloric acid the correct article, and what quantity of water should be added? If this is so certain a cure for canker as Mr. Hunt asserts, it would be a great boon to fruit-growers in this district, as canker on Apple-trees is widespread. SAM. D. LITTLE, *Moghira, Co. Derry, Ireland.*

[No. American-blight is quite different from canker.—Ed.]

GOOSEBERRY BUSHES.

(REPLY TO "N. DEVON.")

WE surmise your Gooseberry-bushes were attacked by red-spider last summer, as you say they were decoloured of foliage, though it is usually during very hot and dry summers that this occurs. Get the necessary pruning done, keeping the centre of the bushes fairly open, shortening the very longest shoots to an upright bud, pendulous varieties to an inside bud, spurting the bottom shoots well back, as the fruit on these young shoots, which oftentimes reach the ground when laden with fruit, gets very dirty. After the prunings are cleared away, get some fresh-slaked lime toned down with a little soot, passing all through a fine mesh sieve, and add sufficient water to make it pass through the nozzle of a garden syringe or fruit-tree sprayer, if you have one. Choose a dry, calm day, and well syringe every part of the bush. This will not only kill what red-spider may be lurking on the wood, it will also prevent the birds (though it may require to be done two or even three times) from picking out the buds, which they did with us the first week in the New Year. Then manure the quarter and fork in the same, when all will be clean for the spring. On the other hand, your mention of Hellebore-powder rather points to the Gooseberry saw-fly, or caterpillar, which, if left undisturbed, in early spring quickly devours the foliage, leaving the bushes devoid of all leaves, consequently the fruit does not ripen. These flies, which they are at first, appear in March sometimes and usually in April. The eggs are deposited on the under side of the leaves, and as soon as hatched, in

about ten days, commence to eat away at the foliage—then is the time to wage war into the camp by searching for the tiny caterpillars and picking off the few leaves at first commenced on, placing a bag or two under the bush to catch those that fall, or the bush may be well shaken and the caterpillars smashed up, or the bushes may be syringed with Hellebore, putting 1 oz. or a little more into 4 gallons of cold water, well mixing together, or dusting with the Hellebore-powder, but as this is more or less poisonous, care should be exercised when gathering the berries, that should any trace remain the fruit is well washed before using. In very bad cases it is wise to take away the soil, say 4 inches of the surface around each bush, and bury it deep in a trench in another part of the garden, replacing with fresh soil, or give a heavy dressing of quick-lime now and dig it pretty deeply in the hope of burying the cocoons, and early in March beat down the soil very firm around each bush and thus enlavour to prevent the flies from coming through the soil, should any be about. In our case, should they appear, we always put four men to look carefully over each bush, and destroy every one that can be seen, and it is seldom we have to search the second time. J. M. B.

NOTES AND REPLIES.

Mildew on Vines.—I have some Vines in a cool-house which had mildew badly this year, and I am told they have had it for some years. The Vines are about fifty years old. The border is a rich loam. The roots are very deep, and there does not appear to be any drainage. Considering the age of the Vines, should you advise the roots being lifted and the border drained, or should they be left alone?—P. WILLIAMS-FARMERS.

[The age of your Vines and the nature of the border are fatal to the prospect of much improvement. We can scarcely comfort you that by an attempt at root lifting you would be successful. With Vines so old the roots probably have gone yards away from the actual Vine border, and the fact of the roots being deep and the border ill-drained makes it difficult to combat mildew. If the border is lush in the house, we should advise the laying of a rod or two on to the surface, so as to encourage an independent root service. If all the rods are so large that this course is impossible, cut down one or two to a convenient point, which will cause the issue of a new cane. Allow this to grow up the roof the first year, and in the following winter when the leaves have fallen gradually bring its point down to the border, fix it there by a peg, and cover a portion, say a foot, with new turfy loam mixed with a little bone meal. Vines when they are so old and ill-rooted need expert treatment to bring them round, but layering as described has been the means of entirely renovating some that had hitherto been almost worthless. Sulphate of iron powdered and spread on the surface of the border, an ounce to the square yard, is a good antidote for mildew given twice a year. Much, too, may be done by careful ventilation to prevent or to encourage its presence. Drought in the border or an opposite extreme will cause it; so, too, will a close, stuffy atmosphere. Air should always be admitted into the house before the sun has

raised the temperature 5 degs. in the morning; indeed, in summer it is even safer to leave a little ventilation on all night. In the meantime, procure a mildew specific and dress the rods while they are dormant, first removing loose bark, tendrils, air-roots, or any appendages there may happen to be; in short, clear away everything possible in the house that will encourage the mildew spores. Probably if you examine your border you may find but few fibrous roots on the surface. If this is so, then search for the large thong-like roots, cut some V-shaped notches in them here and there, and surround them with fresh soil; by these means you could replenish lost roots and restore vigour to your aged Vines.]

Orowing Melons.—I have been trying to grow Melons for the last two years, and have mostly failed. I can only get about one fruit on each plant. If there are two, one of them is not more than half the size of the other. They are grown under glass, with plenty of sun all day. The soil is fibrous loam. Can you give me a hint? If the roots came at all within the influence of the light would that injure the plant?—R. H. K.

[To grow Melons well requires some practical knowledge. You give us no information as to the treatment you have applied, but we may say that Melon flowers require to be fertilised to ensure the resultant fruit to follow. Sometimes by chance Melons will flower, swell up their fruits, and advance to a mature stage, but this is more by accident than custom. Lime is most important in the growth of Melons. Without it in some form they do not everywhere succeed. The fact of the roots coming to the surface would not injuriously affect them, but usually when this happens we advise a light top-dressing of fresh soil to encourage a further extension of this surface root-action. Unless, too, the fertile flowers are open three or four at a time, there is almost a certainty that the first fruit to set and swell will cause the rest to collapse. It is important always to so regulate the growth that several flowers are open together. This can be done by pinching the shoots to encourage fruiting lateral growths. They should never be allowed to become dry or, on the other hand, be over-wet at the roots when grown without artificial heat. Manure-water or anything over-stimulating is fatal if given in their earliest stages of growth. This should be withheld always until sufficient fruits are set and swelling to give a promised crop, say three to a plant.]

Wash for Apricots, Cherries, and Peaches (N. Devon).—Loosen all your trees from the wall and thin out the wood if ill-ripened or unduly crowded, which it may be after such a cold, unless summer as last, though the best time to use the knife on the Apricot and Cherry is during summer, and all that should be necessary now would be to shorten back the breastwood or those shoots pinched to form spurs beyond where they were shortened in summer. The Peach bearing principally upon wood made the previous year, it is necessary to train in a certain amount to take the place of any that ought to be cut clean out soon after the fruit is gathered in early autumn. As a wash for such trees we always use sulphur, soft-soap, and a little Quassia extract. Take a four gallon pot or pail and make a thin wash, thoroughly mixing the soap and sulphur together, squeezing it up with the hands and adding half a pint of the Quassia, keeping it well stirred while painting the trees, which should be done with a soft painter's brush, pulling the latter towards you on wood bristling with fruit-buds, or if used the other way the buds are more likely to get rubbed off. Keep a watchful eye on the trees for aphid, especially on the Cherry and Peach; they are often found before any foliage is visible. Duet with Tobacco-powder on its first appearance, as if allowed to get a footing early in the season it is a difficult matter to eradicate them after; in fact, the trees ought to be inspected every week, twice would be better, as it is very much easier to get rid of these enemies before the young foliage and flowers expand than it is after. After training the trees, loosen the surface border with a fork, take away 2 inches of 3 inches of the loose soil, and replace with good loam well mixed with lime or mortar rubble, wood-ashes, and a little bone-meal, and give a mulching of some well-rotted manure.

J. M. B.

PLANTS AND FLOWERS.

OUTDOOR PLANTS.

LIATRIS.

If not wholly neglected so far as their cultivation in British gardens is concerned, this

Liatris graminifolia dubia.

is neglected in proportion to its merits, and still more in regard to the exceptional tone of colour as seen in the few species of which the genus is comprised. It is a group of North American plants of probably some half dozen or so species, that in form no less than in colouring bear a strong resemblance to each other. It is just possible that in the first-named characteristic—i. e., form—we get a glimpse of what in the garden picture may be regarded as formal, and in the semi-towering inflorescences, though perhaps more especially in their extended columnar outline, may we find cause for complaint. But in these *Liatris* this peculiar form of the flowering spike is so distinctly a part of the genus that it would appear a reason for their liberal cultivation. The term "liberal" is here employed in lieu of grouping, though by common consent the irregular group is among the best ornaments of the hardy plant garden. And if in these *Liatris*, when grouped, we get a formal assembly, so do we by the same token obtain exceptional colour contrasts in the garden as rare as the colour tone itself among good hardy flowers. We have no plants that can compare with these in the early autumn. No gardener would attempt to dispute the value—the exceptional value—of a group, thinly planted, of *Liatris* some 10 feet or more across. Rather, if such a group were seen, would any good gardener anxiously inquire what it was that produces so warm a shade of colour just at the moment when it tones with the many-hued leafage of trees and shrubs all so well-known in the garden. The scraps—the aborted spikes—of these things so generally seen at exhibitions, serve but little to attract those ever on the alert for the useful and beautiful. If, however, the self-same plant were cut at something near ground level, and so displayed somewhat of its true character, there would assuredly be more demand for these things than is now the case. Now and again we see the right thing done, singularly enough with the kind given in the illustration to-day, which at both the Fruit Show at the Crystal Palace in October last and at a subsequent meeting at the Drill Hall, was set up in excellent condition. Indeed, there was something like 4 feet of its blooming stem on view, and as more than half of this length was the flowering portion, the effectiveness of a well-disposed group needed no further demonstration. As garden plants these things are not only hardy, but easily cultivated, growing freely in any ordinary good border soil. The root-stock is peculiar and at ground level, or thereabouts, not unlike so many crowns of *Seakale* incorporated in one. For some few inches deep these crown-thongs or root-stocks remain intact, when the root fibres are more freely distributed. All the kinds are readily increased by division of the root-stock—an operation best performed in early spring—or by seeds that may be sown soon after maturing. There is so little difference in some of the kinds from the garden standpoint that we do not propose to detail them, albeit botanically the species are quite distinct. The general leaf character is long lanceolate or shortly lanceolate, now recurving, at other times rigid. In the flowering some shade of purple, usually of a reddish tone, is seen, the spikes usually columnar or cylindrical. One peculiarity of the flowering in these plants is noteworthy—viz., the tendency to commence opening at the upper parts, and descending instead of the generally reverse way. The following are the best kinds:

L. ELIOGANS, 3 feet to 4 feet high, flowers purple on erect spikes.

L. GRAMINIFOLIA, 3 feet, purple flowers.

L. G. DUBIA (see illustration), height 5 feet or more, flowers purple in long cylindrical spikes.

L. PYCNOSTACHYA, one of the most showy and desirable, 5 feet.

L. SCABIOSA.—This is, perhaps, the largest-flowered kind, 4 feet high.

L. STICATA has dense, close spikes, and grows 3 feet or more high.

L. SQVARROSA, flowers bright purple, stems 2 feet high.

All the kinds named flower in September or October.

CACTUS DAHLIA KRIEMHILDA.

In this new Cactus Dahlia we have a flower of perfect Cactus form, with a tendency to curl inward. The colour of the outer florets is a beautiful clear rose-pink, the centre florets pearly-white. The flowers are borne on long, stiff stems, and show well above the foliage.

needed at all for the herbaceous things, but in all probability it would be requisite for the Roses, and for these the best plan would be to have dug it into the soil at planting time, that is, provided the Roses are of the H.P. class. If of the T. or H.T. class, a good mulching may be given now instead, though for the latter we would prefer digging in very old

Generally speaking, road-scrappings are serviceable by reason of making more workable certain classes of close heavy soils, and are thus useful.]

Polyanthuses. — It is interesting to observe how very froely strong plants of garden Polyanthuses have been throwing up flowers during the open weather we have for some time experienced. How few plants, whether raised from seed or propagated by division, will do that at this time of the year. Because the summer was so cool and generally damp, Polyanthuses retained their leafage wonderfully well, hence now the plants are more than usually robust, and have strong flowering crowns. Some premature bloom does not at all detract from the plant's capacities to flower freely later in the year, especially from the middle of March until the middle of May. Seeing that by making a sowing of seed early in April, on good soil, it is possible to secure scores of strong plants to put out in July, and which will bloom finely the following spring, it is a matter for wonder that Polyanthuses of the fine border strains now in commerce are not plentiful in all gardens. To get extra strong flowering plants the best course is to sow seed outdoors in August on a sheltered border, thus having fine seedlings to transplant early in May.—A. D.

Herbaceous Lobelias. —

I quite agree with what "S. W. E." advances in your current issue as to these plants. Here, in Hampton, I have always had trouble in keeping them through the winter, notwithstanding the staple soil of the district is what is generally termed a light, warm, sandy loam overlying gravel. In other parts of the country, and where dry soil obtains, the plants usually pass the winter quite well, the tufts showing no signs of distress when the hard weather of the winter is past. Frequently I have bought stock to replace that I have lost here, and for years my source of supply was a west midland town, where the soil, judging by that adhering to the tufts, may have constituted good brick earth. I do not remember losing any plants in localities where the soil is opposite to what it is here, but I think other things go hand-in-hand with the soil in these matters. About Birmingham, for example, I had no trouble with these Lobelias, and not only was the soil heavy, but we were at a different elevation. Nearly or quite 450 feet higher was this district as compared to Hampton, and I believe this difference has more—far more—to do with failure and success than any soil. I have had much the same experience with double white Rockets — plants that are vigorous in the extreme in some places, but which in our light soil here can hardly be kept alive. — E. JENKINS, Hampton Hill.

Cactus Dahlia Kriemhilda. From a photograph by G. A. Champion.

NOTES AND REPLIES.

Top-dressing border. — I have a small town garden, the borders of which were well dug last autumn before being planted with Roses, Lilies, bulbs, and herbaceous plants. I shall be glad to know whether road-scrappings would be a suitable top-dressing to put on now, as no manure was used when the digging was done. The soil is fairly heavy. Is it necessary for the Roses to have stable-manure? — M. J. B. L.

[It would depend entirely upon the condition of the soil in the border whether manure was

manure. Much, however, depends upon the amount of soil at disposal, and with a great depth of soil available manure becomes a secondary consideration. Road-scrappings are useful in some soils and for affording better drainage generally. As a rule, however, they are too weedy to be much employed for mulching. If you have knowledge of the quality of the road-scrappings and the class of roads they are taken from, this should help you to decide.

Twitch Grass. — I thought it might be interesting for your readers to know the loring power of Twitch, which you will see by the two bulbs enclosed. In digging over a very old bed I came across two bulbs, through the centre of which you will see that the Twitch has forced its way. — LAWRENCE MORLEY

Levelling and planting (M. R.). — We are not aware of the existence of any uniform charge per man in such matters, which of necessity vary with circumstances. As a rule, the more satisfactory way of levelling and planting is by contract, the varieties of plants and shrubs and their numbers and sizes being clearly defined.

CHRYSANTHEMUMS.

CHRYSANTHEMUMS FOR GROUPING.

WHEN TO INSERT THE CUTTINGS.

(Reply to "AN OLD READER," *Walthamstow*.) Your object appears to be that of keeping your plants as sturdy as possible, and you also prefer to cultivate the thirty varieties you mention, with the object of retaining first crown-buds. Speaking generally, first crown-buds in the season of 1902 have given by far the best results. This is quite contrary to the usual experience, and if you were to treat your plants next season in the same way, it is just possible failure would follow. You hope to keep your plants dwarf by propagating the different sorts as late as possible, hoping thereby to defer the development of the first crown-buds to some extent. In this you may, to a certain degree, succeed, and in order to assist you we suggest that you treat your plants as follows:—Insert cuttings of Mrs. J. C. Neville, Mr. T. Carrington, Henry Weeks, Miss Elsie Fulton, Mrs. J. Bryant, Charles Longley, Duchess of Sutherland, Ethel Fitzroy (late), George Carpenter, Meredith, Madame Paola Radacelli, Mafeking Hero, W. H. Whitehouse (late), Mrs. Henry Emmerton, and Princess Alice de Monaco, in the latter part of January, and, when rooted, pot on and grow them strongly. Let each plant break naturally, and secure the first buds (first crowns) when they develop on the resulting shoots. As far as we can judge, the buds should appear at a suitable period. Any plants which have not made a natural break by the latter part of May should be pinched or stopped, and three of the strongest succeeding shoots taken up. The following sorts—Mrs. Greenfield, George Laurence, Bessie Godfrey, Mrs. T. W. Pickett, Calvat's 99, Lord Alverston, Exmouth Crimson, Lord Ludlow, Princess Brancovan, end Mrs. E. Thirkell—should be propagated in mid-February, and subsequently accorded treatment similar to that prescribed in the first instance. The third and last series represents Mrs. Mileham, W. R. Churchill, Mrs. J. Lewis, Miss Alice Byron, and the Princess, the cuttings of which should be inserted in early March, securing first crown-buds, as recommended for the earlier series. Give the plants plenty of room on the standing ground all through the summer and early autumn, and when the time comes for housing them, avoid crowding. By these means the foliage should be retained on the plants down to the pots, and in such a position they should be ideal for the purpose you require them. E. G.

LATE-FLOWERING CHRYSANTHEMUMS.

THE value of Chrysanthemums for cutting at Christmas can hardly be over-estimated, and they are, in fact, almost indispensable where large quantities of flowers are required at that season for house and church decoration. Such being the case, they are now grown in great numbers in many private gardens as well as by market growers to flower at that particular period, and to have a house of Chrysanthemums in full bloom the last week or so in the year is as easy as earlier in the season. Of course, owing to the efforts of our Chrysanthemum raisers, we have at the present time a much wider range of late-flowering varieties to select from, and in addition to this it has been proved by actual experience that many of the large-bloomed Japanese or exhibition sorts are, when specially grown, particularly useful for this purpose, so there is no difficulty in this direction. The two chief essentials to observe in the cultivation of these late-flowering Chrysanthemums are not to propagate the cuttings earlier than mid-March, and to keep the plants outdoors as long as possible before housing them. I erect a temporary structure over my plants, consisting of posts to form uprights, on which laths and wires are fastened, the whole when finished forming a kind of skeleton span-roofed house. Mats are used to afford the necessary amount of protection at night, and on several occasions the mats had to be left on during the day, and here the bulk of the plants remains until the second week in December, when they are housed. By this it will be seen that as far as accommodation is concerned they

make little or no difference, because by the time they need housing the bulk of the large-flowered varieties will have passed out of bloom and the stools be removed elsewhere for propagating, so that they simply take the place of the latter and prolong the Chrysanthemum season well into the New Year.

Regarding the most suitable of the large-flowered Japanese varieties to grow for late flowering, the following have yielded splendid results, and can, therefore, be highly recommended—viz., Madeline Davis, H. Wseks, R. Hooper Pearson, Chatsworth, Bonnie Dundee, and Mutual Friend. When to these are added the true late bloomers, such as L. Canning, Niveum, Roseum superbum, Souvenir de Petite Ami, Caprice de Printemps, Princess Victoria, Rubrum perfectum, Boule de Neige, W. H. Lincoln, Mrs. S. Filkins, and the three following single-flowered sorts—Eucharis, Golden Star, and Cannell's Perfection, it can be seen what a really brilliant display may be had. Of course, the large-bloomed sorts come quite out of character grown in this way, but in the estimation of many this is looked upon rather as a gain than as a defect, as they are considered to possess a higher decorative value than when grown as single blooms for exhibition; at any rate, there can be no question as to their utility where quantities of flowers are in demand at the festive season. A. W.

SOME JAPANESE NOVELTIES OF THE PAST SEASON.

THE undermentioned list of new Chrysanthemums should follow the selection of novelties described in the issue of GARDENING ILLUSTRATED for December 27th last. Twelve superb exhibition varieties were described in detail on the occasion referred to, and the present set is also worth attention.

MISS E. RICHARDS.—A large Japanese bloom of a clear yellow colour, reminding one of the blooms of Edith Tabor, but not so long in the petals as the flowers of that excellent variety. The petals are broad and of good substance. Two plants were shown before the N.C.S. floral committee on September 22nd last, these being dwarf and sturdy.

NETLY BLAKE.—This is not an exhibition variety, but useful for decoration in late September and early October. The colour is a lovely terra-cotta-crimson, with a golden reverse to the fairly broad petals. It is said to be a seedling from Mme. C. Desgrange, though far superior in every respect to that variety. Height between 3 feet and 4 feet. It was exhibited before the N.C.S. floral committee on October 7th last, and was awarded a F.C.C.

BLACK PRINCE.—The blooms of this are too small for exhibition, but for conservatory decoration, and in cases where a free display of medium-sized blooms is desired, a special note should be made of this variety. The colour is a rich deep crimson, with golden reverse. In appearance the blooms somewhat resemble those of Edwin Molyneux. Height about 3 feet, free flowering. Awarded F.C.C., N.C.S., October 7th last.

MARY PERKINS.—A very refined type of incurved Japanese, petals long and fairly broad, slightly curling and incurving at the ends. Colour a beautiful canary-yellow. Useful for the earlier exhibitions. Awarded a F.C.C. by the N.C.S. October 7th last.

SIR WILLIAM AGLAND.—This is a large flower of even and drooping form, with long (8 inches), twisted petals. Colour reddish-bronze.

COUNTESS OF HARROWBY.—In the blooms of this variety we have what may be regarded as a chaste and beautiful type of exhibition Japanese. The petals are long and drooping, slightly curling and incurving at the ends; colour a lovely shade of soft pink, lined and suffused with a deeper shade of the same colour, with a yellowish centre. The blooms are very large and full.

GRANDEUR.—This is said to be a seedling from Mons. Chenon de Leche, and it must be admitted the blooms partake of the form of that excellent sort; colour rich chestnut, deepening towards the centre, with a bronze reverse.

Mrs. HARRY EMMERTON.—This is an Australian raised seedling of great promise,

developing well from any bud, and giving good blooms when grown in the orthodox fashion or on single stems in 6-inch pots; colour amber-yellow, slightly richer in the centre. The petals are long and drooping, and of medium width, and build up a full bloom of large size and even and drooping form. An ideal exhibition bloom.

LADY CONYERS.—Little has been seen of this variety, but it will doubtless play an important part in future exhibitions. It is an English-raised seedling, and may be described as full and of massive build, the petals broad and of splendid substance, incurving at the ends. Those who have seen the blooms speak of their being somewhat in the way of those of Mrs. Geo. Mileham, but larger and with more substance than that variety; colour inside, and this is always apparent, good rosy-pink, with a silvery-white reverse.

EXMOUTH RIVAL.—A very striking Japanese reflexed bloom of good form, petals evenly arranged and drooping, and of medium width. The colour is a rich crimson.

VISCOUNTESS CRANBOURNE.—This is the finest yellow of the season. In the open classes for six blooms of one variety, this was the best at the great November show of the N.C.S. last season. The petals are long and drooping, broad, and of good substance, and they are also slightly pointed, and intermingling pleasingly.

CAPT. PERCY SCOTT.—This is an incurved Japanese bloom worth noting. The bloom large and of massive build, and also of good substance, petals of medium width, curling and incurving at the ends; colour rich, clear yellow.

WILFRED H. GODFREY.—A very nice Japanese flower, with long, somewhat drooping petals of medium width and pointed, incurving at the tips; colour rich, rosy, chestnut-crimson, with bright golden-bronze reverse. A striking flower.

COUNTESS OF ARHAN.—Another lovely and refined Japanese, petals quite 8 inches long, and also broad, developing blooms of drooping form quite 9 inches across; colour cerise-pink on a pale creamy-buff ground. W. V.

Chrysanthemums—stopping and timing (Manner).—The dates given below for stopping your plants, and the kind of bud you are to retain in each instance, are given especially for growers in the Midlands, which will answer your purpose just as well. Growers in the neighbourhood of London, and those also further south, should commence operations a week or so later than the dates given in this reply. If this rule be carefully observed the interests of both districts will be studied.

Chas. Davis—when to stop or pinch plants, natural break; which buds to retain, any buds in late August; approximate height, 5 feet.

Florence Davis—May 21st, first crown, 5 feet.

Jane Molyneux—March, 1st week, second crown, 4 1/2 feet.

La Triumphant—natural break, second crown, 5 feet.

Mrs. Barkley—April, first week, second crown, 4 feet.

N.C.S. Jubilee—March, last week, second crown, 5 feet.

Oceana—May 21st, first crown, 4 1/2 feet.

President Borel—March, last week, second crown, 5 feet.

Pride of Madford—May 21st, first crown, 5 feet.

Rayonsble—natural break, second crown, 5 feet.

Secretaire's Pierrea—end March, second crown, 5 1/2 feet.

Sir Redvers Buller—March, last week, second crown, 5 feet.

Soleil d'Octobre—natural break, second crown, 5 feet.

Souv. de Petite Amie—natural break, any buds in late August, 3 1/2 feet.

W. Seward—natural break, second crown, 5 feet.

Mons. William Holmes—natural break, any buds in late August, 4 feet.

Roi des Precoees—natural break, terminal (decorative variety), 3 1/2 feet.

Vesuvius—natural break, terminal (decorative variety), 3 feet.

Miss Lucy Cheesman—March, last week, second crown, 5 feet.

Vivian Morel—natural break, any buds in late August, 5 feet.

Mr. L. Fryett—about May 21st, first crown, 4 1/2 feet.

Source d'Or—natural break, terminal (decorative variety), 4 feet.

Alice Byron—May, last week, first crown, 5 feet.

Edith Tabor—May 21st, first crown, 6 feet.

Eda Prase—May, last week, first crown, 5 feet.—E. O.

Request to readers of "Gardening."—Readers, both amateur and in the trade, will kindly remember that we are always very glad to see interesting specimens of plants or flowers to illustrate, if they will kindly send them to our office in as good a state as possible.

ROSES.

ROSES AND FOXGLOVES.

In many portions of the garden the happiest effects are gained by informal planting, and numerous herbaceous perennials, annuals, and biennials, as well as flowering shrubs and trees, are specially adapted for enhancing the beauty of the semi-wild garden. In the accompanying illustration we notice the charming effect of white Foxgloves flowering against a verdant background, while in the open space in the foreground bush Roses are blossoming profusely. Until a few years ago old-fashioned roses, such as Maiden's Blush, York and Lancaster, and the Cabbage Rose, all of which make fine bushes, were rarely seen outside cottage gardens; but now that the fashion for so-called "Garden Roses" has set in, these old

the summer, when they are laden with countless flowers. The tall-growing Evening Primrose (*Oenothera Lamarckiana*) is a fine plant for the informal garden, and is very effective, as the sun sinks, grouped at the margin of shrubbery and coppice, or in open spaces verging a woodland path. The Bergamot or Bee Balm (*Monarda didyma*) is valuable for its deep crimson colour, and if a large mass 20 yards or so in length, and 3 yards or 4 yards in breadth, is planted, it has a bright effect in the landscape, even from afar. White Honesty (*Lunaria*) and the single Rocket are two good plants for massing, forming clouds of white if viewed at a little distance. The white Japanese Anemone is an excellent plant for the informal garden, since its flowers are beautiful, and if once well established it possesses sufficient vigour to hold its own in the absolutely wild garden in the face of the strongest oppo-

many pages of GARDENING ILLUSTRATED would be requisite if a full list were to be given. Though space does not admit of a consideration of dwarf plants, attention may be drawn to *Erysimum Peroffskianum*, an annual with brilliant orange flowers growing from 1 foot to 18 inches in height, which will succeed on slopes of poor soil if a packet of seed is sown broadcast and the surface-soil lightly raked over after the sowing is completed.

S. W. F.

NOTES AND REPLIES.

Liquid-manure applied in winter.

It is not generally known that Roses benefit considerably by copious applications of sewage or other liquid-manure poured on the ground during the resting period. It is lamentable to witness the waste in some establishments of good liquid-manure that could be used now as a fertiliser to beds of Roses. Lightly fork up the surface beforehand, then pour it on the ground, not immediately near the plants but between the rows. The spring rains will take down the fertilising material ready for the requirements of the plants when needed. Such applications are safe, whereas there is always an element of danger in the indiscriminate use of liquid-manure when the plants are growing, besides which the liquid is more readily applied now than later on. If a more reasonable method of manuring were adopted there would be no need to resort to doubtful artificial stimulants which appear so enticing in print, but which, if recklessly used, are a source of positive danger.—**ROSA.**

Protecting Roses.

The recent spell of wintry weather must have made many Rose-growers feel anxious as to its probable effect upon their plants in the open ground, especially the Tea Roses. Many are the devices of the cultivator for keeping the frost at bay and providing a warm covering during the winter months. Plenty of dry leaves or Bracken is the remedy advised, but to those who, like myself, live just on the outskirts of London the latter article is not readily obtainable, but there is a very good substitute, although I have not seen it mentioned by your valued contributor "Rosa," or any of your other correspondents. It is the long rough Cocoa-nut-fibre refuse from 4 inches to 6 inches in length, which, if carefully spread between the rows of our Tea Roses, affords them a splendid protection, as the fibre in this condition throws off the heavy rains and does not, like the ordinary fibre, consolidate, which is a most important factor. This long rough fibre is sold by weight, and as it is very light a considerable quantity can be obtained for a few shillings. I should much like to know whether any of your readers have tried this stuff as a protective, and if so, with what result?—**FIBRE.**

Rose Sir Joseph Paxton.

Among all the interesting and profitable contributions which "Rosa" has supplied on Roses and their culture, I cannot recall any mention of one variety which has served me better than that which for a long time has been grown by me. I refer to the old H.P. Sir Joseph Paxton. I think I must have got my plant forty years ago, and for a long time I did not do it justice, but seven or eight years since I took it in hand, split up the clump into which it had grown, and made four or five plants of it. It has repaid me liberally for cultivation. From early June, if not before, to the end of November it is never without blooms; sometimes a long, strong shoot of the previous year is laced with them. Old as it is, it is well worth notice for cutting for the house. Teas and their hybrids do not answer so well with me as Hybrid Perpetuals. Varieties of the former seem to have been raised and sent out of late years for "button-hole" purposes, regardless of perfume, so that

Roses and Foxgloves. From a photograph sent by Mrs. Dumas, Reecdale, Walton-on-Thames.

varieties are again sought after, and have found their way back into many a garden. The Cabbage Rose stands unrivalled for perfume, and a large bush thickly set with flowers spreads its fragrance afar on the summer air. Such great bushes, over whose heads many seasons have passed, may often be found in the humble plot of the cottager, whence, loaded with blossom in "the month of the Roses," they wait a welcome greeting of the most delicious of scents to the passer-by. Many of the more vigorous Hybrid Perpetuals, Teas, and Hybrid Teas, if intelligently treated, will form good-sized bushes, and, although the standard Rose as ordinarily seen cannot be recommended for artistic effect, such a strong-growing variety as Gloire de Dijon will make a head 3 feet and more through and afford a pleasing picture, while some of the summer-flowering Roses grown as standards will form enormous heads, beautiful for a few weeks in

sition. It has been known to conquer even the Coltsfoot, one of our most rampant weeds, where the leaves of the latter were from time to time picked off. Solomon's Seal is easily naturalised in open spaces in woods, and succeeds in moist soil by the side of rivulets. It is pretty when bearing its pairs of drooping flowers, and in the autumn its dying foliage assumes attractive tints. The grand *Acanthus latifolius* is a noble plant, far better fitted for the semi-wild garden than for the border. Its deeply-cut, arching leaves are perfect in contour and poise, and in vigorous specimens the flower-spikes are thrown up to a height of 7 feet or more. Perennial Starworts or Michaelmas Daisies are indispensable among autumn-flowering plants, and the strongest of them will hold their own well in the wild garden. The plants already mentioned do not form a third of the strong-growing subjects suitable for use in the informal garden, but

Shakespeare could not now use the Rose as the embodiment of sweetness. Mrs. W. J. Grant is very useful with its umbel-like inflorescence, each bud with a sufficiently long stalk. But for fragrance as well as for late blooming, commend me to the H.P.'s. I had four or five of them before me the first week in December, among them Ulrich Brunner, and on Dec. 3, after the frost and cold of yesterday (mark the date), cut quite a pretty partially-expanded bud of Annie Wood, of the richest colour. How strange it is that the celebrated "Her Majesty" will not expand here, indoors or out, or, as I have ascertained, in the gardens of a nobleman in the South of Devon.—C. R. S., *South Cornwall, Dec. 6th.*

INDOOR PLANTS.

THE GRASS GUM-TREE

(*XANTHORRHEA HASTILIS*).

THE Australian Grass Gum-trees, of which there are about a dozen known species, are rarely seen in cultivation in European gardens. They are really sub-arborescent Rushes, with more or less sharp angled leaves, each 18 inches to 2 feet long, borne in tufts at the top of the Fern-like stems, 2 feet to 20 feet in height. The flowers are very small and whitish, borne on dense spikes 2 feet to 10 feet high. The stems exude a dark-red or brown resin, which was at one time used in the making of picric acid. Two species, *X. hastilis* and *X. quadrangulata*, have been grown in the Trinity College Botanic Gardens, Dublin, our illustration showing a plant of the former which flowered last year for the second time since it has been in the gardens thoro. Some very fine specimens of the Grass Gum-tree, and of which we had charge for some time, were sent from Australia to the Colonial Exhibition which was held in the gardens at South Kensington in 1886. They were received in large tubs, and were growing in what seemed to be pure sand.

NOTES AND REPLIES.

Old potting soil.—Someone asked me the other day what I did with my old potting soil — soil, once used. My reply that I never used it again for potting seemed to cause surprise. The fact that I am in a position to get what loam I require without much trouble accounts for it, but I think to use over again for potting, soil that has stood in a pot perhaps for a year or two is unwise. The best use for old potting soil in my opinion is not in the house, but out-of-doors in the border where it can be incorporated with stronger material. Some plants lose vigour after a time in pots, through the soil having become spent.—TOWNSMAN.

Justicia calycotricha.—This is a valuable winter blooming plant, the colour of the flowers being scarce among plants of this class. It forms an upright, sparsely-branched specimen, and is terminated by a cluster of pleasing yellow flowers. The calyx segments are long and narrow, and, being gathered together in a compact head, form quite an effective feature, which is enhanced by the flowers that protrude therefrom. The individual flowers are only about an inch long, and remarkable for their pubescent character. It is of easy culture, but as the plants are apt to become leggy, frequent propagation is necessary to ensure good specimens. Cuttings of the young growths strike readily during the spring, and, if grown on freely during the summer, will make good flowering specimens the following winter.

Indian Azaleas for house furnishing.—Indian Azaleas have much to recommend them to small growers; not the least is that they may be obtained at a very small cost, and from now onward for the next three months may be bought of any florist or at the auction rooms. Last year, calling on a friend in a large garden he showed me plants in 6-inch pots a mass of bloom, and he told me they did not cost 2s. each. Another merit these have is that they are not quick growing, taking up a lot of space; added to this they will bear several degrees of frost when dry, and (at least) few things stand house furnishing better than

these when brought on cold. Last autumn a large plant stood in a big, dark room here for six weeks and continued opening its blooms. These Azaleas may be had in bloom the greater part of the year if their growth is arranged accordingly. I have had them for eight months, being favourites here. They are not difficult to manage provided they are not allowed to suffer from want of water and are kept clear of thrip.—J. CROOK.

Campanula pyramidalis.—I am sending a photograph of *Campanula pyramidalis* alba, grown according to the directions given in *GARDENING ILLUSTRATED* of July 6th, 1901. The seeds were sown in February of that year, but I did not know how to treat them until the article appeared. The photograph is, I fear,

3-inch pots, filled with silver-sand and leaf-soil in about equal parts, and put in a close case, avoiding too much moisture, or the tender shoots may damp. In choosing the cuttings avoid any that are showing flower, as these fail to throw up shoots from the base and never make good bushy plants. Some increase their stock by the leaves, placing these in pans of similar compost, but not keeping close as in the case of cuttings. I have had better results from cuttings than from leaves, so stick to this process for increasing my stock each spring.—J. M. B.

Anoiganthus hreviflorus.—Some of the South African bulbs do not readily conform to pot culture, a charge which cannot be brought against this *Anoiganthus*, as with

The Grass Gum-tree of Australia (*Xanthorrhoea hastilis*), which bloomed in 1902 in the Trinity College Botanic Gardens.

too small for printing, but may give you some idea of the beauty of the plants, though not of their size. The tallest measures 11 feet from the ground, including pot, the others 8 feet and 9 feet. Placed in a staid entrance hall they were greatly admired by visitors, and remained there from July 27th to October 9th of last year. The old blooms were picked off as they withered, and the plants were watered twice a week with soot and water.—(MRS.) E. D. BAIRD, *Castle Mains, Douglas, Lunenburg.*

[Well grown plants, but reduction too great for reproduction.—ED.]

Increasing Begonia Gloire de Lorraine.—A few of the earliest to bloom should be cut fairly hard back and kept on the dry side, but syringed daily, when new growth will soon push. The cuttings should be taken off when about 3 inches long, and inverted in

reasonable care and attention it will both grow and flower well. The fact that its usual season of blooming is during the first two months of the year is another point in its favour. It forms a solid brownish bulb, from whence the erect leaves are pushed up to a height of about a foot. They are just overtopped by the flower-scape, which is terminated by a loose umbel of blossoms. The individual flowers are nearly a couple of inches long, but so curiously constructed that they appear at most to be half opened. They are of a pleasing light orange-yellow colour. It succeeds with ordinary greenhouse treatment, and during the growing season should be watered freely, but must be kept dry when dormant. A compost made up of two-thirds good loam to one-third well decayed leaf-mould, and a liberal dash of silver-sand, will suit this *Anoiganthus* well.

FERNS.

WOODWARDIA RADICANS.

Thus, of which an illustration is here given, is one of the noblest of the few plants belonging to the genus. It is a native of Europe, being found, it is said, in Spain and Italy, but is more generally regarded as a native of Madeira and the Azores. It is certainly the best Fern that can be used for a large vase or pedestal. When planted a little above the line of vision, its broad, rich, bright green, pendulous fronds have a beautiful effect, or planted in an elevated pocket in the fernery (as here shown) it is quite as effective. This Woodwardia is easily grown, requiring good drainage and soil consisting of turfy loam and peat in about equal parts, to which must be added a fair proportion of sharp sand. When growing freely abundance of water is necessary, so as to keep the large fronds in good condition. It will do quite well in a cool fernery, care being taken it is not given too hot a position, as then the fronds are liable to the attacks of black strips, which spoil their appearance, changing them to a nasty brown colour. It obtains its specific name from its rooting and forming a young plant near the tip of the frond. We have seen plants with fronds of considerable length. The rhizome is creeping, and clothed with large brown, chaffy scales.

Woodwardia radicans.

VEGETABLES.

FORCING ASPARAGUS.

This is one of the easiest vegetables to bring forward, and may be had in season from November until heads are cut from the open in April. It is useless to expect good grass, unless roots of three or more years' growth are to be had, and then much better results would be forthcoming had no cutting been practised from these said roots after the middle of May the previous year. Many ways are devised by gardeners to bring in this delicious vegetable, but none are more satisfactory than the old hot-bed system of three parts freshly collected leaves (Beech, Oak, and Spanish Chestnut are the best and most lasting), and one part long stable litter—the last more or keeping the bed together than heating, as a good bed of new leaves will maintain a good lasting heat throughout the spring, unless the winter is exceptionally cold, with much snow, and then new linings to the frame occasionally will put matters right. After the crowns are exhausted and cleared out the bed in the frame should be deeply forked up, working in fresh leaves and a little short manure from the stable, when another batch of roots may be introduced. A couple or 3 inches of leaf-soil should be put over the bed, and about 4 inches of the same material over the crowns, first passing it through an inch sieve. Pack the crowns closely together and keep the frame closed until the grass appears, when give a chink of air whenever the weather is favourable. Cover the glass lights with mats at night whether frost threatens or not. When forced in this way it is seldom any water is necessary, but should it be, let it reach 85 degs. or 90 degs. applied with a rose can, and not heavy waterings, or they would cool the bed. A space of 10 inches or 12 inches must be allowed from the glass for the produce to push up.

J. M. B.

the seeds singly in small pots—large thumbs for preference—filled with nice sharp soil, in which leaf-mould largely predominates, and place in a propagating case on a hot-bed or over the hot-water pipes, covering the pots with a sheet of glass in the two latter cases. If the soil is in a moist condition, water will not be required until the seeds have germinated, the application of much water at this early season causing the seeds to decay instead of germinate. When through the soil, remove the plants to a light position in the warmest part of the house—a shelf over the hot-water pipes being an excellent position—and shift them on into 48 sized pots so soon as the plants have made a pair of true leaves, using as compost on this occasion nice turfy loam, with a little spent Mushroom-dung and leaf mould added. Place a stick for the support of the plants, and tie them thereto and return them to the shelf. Perform the potting in the house in which the plants are growing, and use the compost in a warm state to avoid chilling the roots. In the meantime, prepare the house or pit in which they are to be grown, taking the precaution to give the structure a thorough cleansing. With regard to varieties, most

quickly-maturing varieties, which are termed forcing Cauliflowers. Sow the seed thinly in a pan or box, and raise them in a cool greenhouse, placing them close up to the light to ensure dwarf, stocky plants, and prick off into other boxes or a frame when large enough to handle.—A. W.

Broad or Long-pod Beans.—Whilst few persons now sow Long-pod Beans in the early winter, they can be sown at any time now, provided the soil be dry enough to enable drills to be drawn without unduly hardening the ground. Whilst it is sometimes advised to sow these Beans thus early on warm borders, it must not be overlooked that ere the plants carry pods warm weather will have set in, and a south border may then prove to be much too hot for them in June. Better sow out in the open quarters of the garden, where the plants will have better chance to resist heat later on. These Beans do best when ground is trenched and manure buried down to induce deep rooting. Failing general trenching, then it is well to make trenches for each row, as for Celery, putting the manure deep. In this case the trenches can be noarly filled with soil, and the rest can be added after the plants have got into bloom, and if the soil be dry have had before the rest is added a good soaking of water. Sow the Beans thinly—that is, fully 6 inches apart. Two very fine varieties are Green Long-pod and Green Giant.—A. D.

GARDEN PESTS AND FRIENDS.

THE CURRANT BUD-MITE.

FOURTEEN years ago, when we came to our present garden, the Black Currant-trees were thick with this pest; we picked them off, spending an hour or so at odd times, and got a large crop of good fruit. Thinking we could clear it out, we dug the trees out, burnt them, and got a new stock from a place where it had not appeared, planting them in new ground as far as possible from where the Currants had been before. In three years they were as bad as the old stock, and we kept on the system of hand-picking, the result being that every year we had enormous crops of fine fruit, the branches having to be supported to prevent breaking down with the weight. Our next neighbour tried cutting down and burning, with the result of total loss of crop for two years, and a small one for one or two years after; but the pest reappeared at once as soon as the plants began to bear. Practically three years' crops were totally lost without the slightest benefit, whilst we had and have very heavy crops every year except the last, when the flowers were destroyed by late and hard frosts. We have tried and seen tried for the last fourteen years everything which has been recommended, and all the experience goes to show that nothing more is needed than hand-picking at odd times. What we lose in numbers of bunches is gained in the size of the remainder; and the crops are, with the one exception mentioned, as heavy as the trees will or can carry with the help of props. We could not wish for better crops or finer fruit, and the present system is very little trouble. If anything, it is a distinct advantage, like the thinning of Grapes; what we lose in numbers we gain in size and quality of fruit.—THOMAS FLETCHER, *Grapenhall, Cheshire*, in "Gardener's Chronicle."

Blight on leaves.—Can you kindly tell me whether the blight affecting these two leaves is one and the same thing, and also the name of it and the remedy?—L. B.

[The two leaves you sent are not affected by the same "blight." The Geranium-leaf is attacked by a fungus belonging to the genus *Cercospora*, I believe, but the fungus is not in a condition in which it can be named with certainty. Pick off the infected leaves and burn them, and keep a good watch on the plants, and as soon as you see the slightest reappearance of the pest, spray the plants with dilute Bordeaux-mixture once a week till there are no further signs of it. The leaf of the India-rubber plant has apparently been subjected to some change of temperature or drip. You cannot find traces of any fungus, and the above mentioned causes often discolour the leaves of this plant.—G. S. S.]

gardeners have their favourites, but for early fruiting one of the prolific, early bearing kinds, such as Rochford's Market, Market Favourite, and Everday, give the best results.—G. P. A.

Early Carrots.—Where young Carrots are in demand as early in the season as they can be produced, no time should be lost in making up a hot-bed on which to grow them, unless a heated pit can be set apart for the purpose. The hot-bed should consist largely of tree-leaves, and be well consolidated by treading as it is made up. After placing the frame in position, put in from 9 inches to 12 inches of light rich soil, and after the heat has subsided sow the seed either broadcast or in drills drawn about 9 inches apart. Suitable varieties for this purpose are the various types of Forcing French Horn offered by the leading seed firms, one named Inimitable being particularly good and early in coming into use.—G. P.

Early Cauliflowers.—Owing to the mild weather, autumn-raised Cauliflowers are in rather too forward a condition, and the earliest plants will, unless they receive the needful check from colder weather, hardly be worth planting. In any case it is well to be prepared with a batch of younger plants; and to do this sow now one of the compact,

GARDEN WORK.

Conservatory.—Freesias are not particularly showy, but they are sweet, and consequently attractive for the drawing-room, and a group in the conservatory never lacks admirers. They are easily grown and flowered if the bulbs are fine and well-ripened in the sunshine. The best place for this ripening is on a shelf near the glass, and in this condition they can remain till they have had a good roasting in the sunshine, and early in August the bulbs should be repotted, placing about eight or nine bulbs in each 5-inch pot. They may be started in a cold frame with the lights off till some progress has been made. When taken indoors place on shelves near the glass, where there is a night-temperature of 50 degs. if wanted in flower. But they will flower just as well in a lower temperature, only, of course, they will not be so early. Among variegated shrubs which may be grown in pots suitable for a cool conservatory, *Coprosma Baneriana variegata* is worthy of notice. It is rather slow of growth, but having secured it will annually increase in size and usefulness. The best way to propagate this plant is to set out an old plant in May and peg it close down into the soil, which should be of a light sandy nature. Every bit of shoot, where it comes into contact with the soil, will form roots. I have seen failures with cuttings, and when they root they are a long time about it. *Eurya latifolia variegata* requires somewhat similar treatment, and when grown to specimen size is very useful as a foil to other things. There is plenty of flowers now in Azaleas, Camellias, Lilacs, Deutzias, Arum Lilies, Mignonette, etc. Liquid-manure in a weak, clear condition may be given to any plant coming forward for bloom, and which has filled the pot with roots. *Chorozema Lowii* and others are very useful winter-flowering plants, and the *Epacris* are coming on now. *Genista fragrans* lasts a long time in the conservatory, but it is one of the worst plants to take indoors, especially where gas is burnt. Those who have only grown this plant in a pot have no idea what can be done with it planted out in the conservatory, and when planted out it never ceases altogether to blossom winter or summer. Cut back winter-flowering Heaths when they go out of bloom. This has not been a good season for *Erica hymalis*. The wood failed to ripen well and flowers are thin.

Stove.—We want more sunshine, and doubtless with more sunshine will come frosty nights, but anything is better for the plant-grower than the dark, gloomy days of the past month. Where the temperature of the stove has ruled low the plants will now be in a better position to respond to warmth. It wastes the energies of the plants to force hard when there is no light to harden the growth. The quiet season is now near its close, and with more sunshine more activity will be visible, not only in the condition of the plants, but among insect pests if any are present on them. The experienced man knows how to deal with these, and he knows also that a supreme effort should be made now to get rid of mealy-bug. Personally, I dislike brown scale worse than bug, and if I had any plants badly infested with scale I should destroy them at once and start again with clean plants. The vaporiser will destroy most of the insects in the stove if used occasionally. Including a few Orchids, there will be a good show of flowering stuff now, and the bright foliaged plants which are now so numerous will add their quota of colour. Early-starting Gloxinias will be moving now. I have had them in flower in February, and they are more useful than later. Seeds of these and Begonias may be sown now or shortly.

Early Melons.—A low, warm house may be planted any time now. There must be a bottom-heat of 85 degs. or so to start with, and a top heat of 65 degs. to 70 degs. at night. Very little ventilation will be required at present, but, still, as the days lengthen, air must be given to ensure sturdy growth. Melons want a rather strong, adhesive loam to do them well. They will grow in lighter soil, but the finish is not often satisfactory. Good yellow loam mixed with a little boned soil, all that is required at the start. Later, when

the fruits are swelling, especially if the crop is heavy, liquid-manure can be given. One or two good top-dressings of the same kind of loam can be given during growth and pressed firmly round the plants. Every Melon-grower has his favourite sorts, and at least one good scarlet and one good green-fleshed variety should be grown.

Roses under glass.—A house of Roses breaking into growth is always interesting. There are so many shades of colour among the young growths, and this is more noticeable when the plants are in pots and grown in a house where is a bed of leaves in a pit, and the pots plunged or partly plunged therein. If I were building a house for Roses in pots I should build a span-roofed structure with rather a flat roof and a pit to be filled with leaves in the centre. It is a good many years since I first saw Roses grown in this way, and I have never seen them so well done under other conditions, nor yet so free from insects and mildew. Roses recently potted up will not stand forcing, but they will flower well if pruned rather hard back and allowed to come on quietly, especially if helped in a leaf-bed.

Vines in bloom want careful management. Shake the rods daily, or distribute the pollen in some other way. Night temperature, 65 degs. Give air when required at the highest point of the roof only. There must be no cold draught through the young foliage. The syringe should be laid by for a time, but the atmosphere of the house should not be abnormally dry or overheated, or the flowers may not set so well. Genial conditions are best for a perfect set.

Window gardening.—Ferns, especially Maiden-hairs, are usually kept drier during winter. Sometimes the Maiden-hairs are dried off, and if the temperature is low the new fronds come away strongly when the days lengthen and are improved by the rest, but the time is coming now when a little more water will be required; at any rate, as soon as growth is visible moisture will be required, and the chill should be taken off the water for indoor plants now.

Outdoor garden.—At this season, when other things are not so pressing, and one is taking stock of the resources in the way of bedding-plants, one generally glances at the seed lists as they come to hand to see if we can utilise anything in the way of annuals and perennials that will flower the first season if sown in heat. *Lobelia fulgens* Victoria makes a beautiful mass, and comes true from seed, and if sown in February and helped in heat the plants will be ready to go out in May. Several beautiful crosses have been obtained, but they are rather scarce yet. Sweet Peas sown thinly now, or singly in small pots and planted out when the weather is suitable in March, will flower early. Navy Blue, Lovely, Maid of Honour, Mars, Mont Blanc, Mrs. Eckford, Novelty, Othello, Orange Prince, Peach Blossom, Prince Edward of York, Sadie Burpee, Venus, Waverley, Prince of Wales, are among the best. But there are now far too many varieties. There are many beautiful varieties now of hardy Primroses, including white, blue, and other shades of colour, and there is a *Polyanthus* Primrose, which is good either for massing in the border or for growing in the cool house. *Primula rosea* may be grown from seed, and this is a delightful plant on a shady rockery, or in a pot in a cool house. Sow the seed in gentle heat, and when large enough prick out on a shady border, and the plants will flower twelve months from sowing. We generally sow blue bedding *Lobelias* in autumn, and grow them on steadily in the seed-boxes till February, and then prick off. Many delay sowing till January or February, and give more heat. Many seeds, such as of *Lobelias*, *Petunias*, and *Begonias*, are minute and should be covered lightly, the soil in the pots or pans being pressed down firmly and evenly before sowing the seeds, and again after the covering has been applied. We generally cover fine seeds with sand, and sprinkle with warm water from a fine-rosed pot, and then place on shelf in warm house till germination takes place.

Fruit garden.—There is room for more good Peare—I do not mean exactly more kinds of Pears, although, of course, a good new Pear

is always valuable, but it is wonderful how long it takes for a new Pear to get known. The truth is, planters, at least very few of them, plant Pears they know little or nothing about, and the Pears I am now planting and intend recommending are not new. If I had room I should like to try more of the new varieties, about which I know so little. I should like also to raise seedlings from the best varieties, even though I might never see them bear fruit. The raiser of seedling Pears knows that when his seedlings bear fruit, as they will some day in the future, if the fruit is worthless he will have a strong, robust stock upon which he can place a head of *Doyenne du Comice*, or *Marie Louise*, or any other good variety that will bear in a short time bushels of fruit—supposing, of course, the soil is suitable. A good, deep loam, reasonably drained, is the best soil for Pears on Pear-stock. Where the soil is naturally cool and moist, the *Quince* is a good stock for the Pear, but all Pears do not do well upon it. *Marie Louise*, for instance, is not often found on the *Quince*. Among the best known Peare are *Doyenne du Comice*, *Marie Louise*, *Jargonelle*, *Williams' Bon Chretien*, *Pitmaston Duchess*, *Clapp's Favourite*, *Glou Morceau*, *Darondeau*, *Louise Bonne*. The planting and pruning of Peare should be on its way and completed as soon as possible. If fruit is wanted on pyramids do not over-prune the branches but look to the roots.

Vegetable garden.—The proper rotation of crops and the proper application of manure are important matters, and should, in a sense, be linked together. It has been said that when the manure supply is abundant, the labour efficient, rotation becomes less urgent. No doubt there is something in this, though it is quite possible to make too much of it. We know that Potatoes and Onions have been grown year after year upon the same land without showing much deterioration, but these two crops occupy the land but a comparatively short time. Potatoes are planted in March and lifted in September or October—a mere matter of six months. Onions are cleared off in even less time, and as the land generally remains dormant the remainder of the year it gets thoroughly rested. But when land is planted with Cabbages or other greens year after year, the soil gets no rest without a rotation. The simplest rotation is Potatoes and then Greens, afterwards Peas, Beans, and Celery, then tap-rooted plants, such as Carrots, Parsnips, Salsify, Beet, etc. Of course, a suitable rotation should be marked on the plan before the land is manured, so that a prospect can be secured for the tap-rooted plants, otherwise the latter may be spoiled by forking out, as it is termed. If land is manured for tap-rooted things the manure should be buried very deeply. The finest lot of Salsify I have ever seen was sown over manure, but the manure had been placed in the bottom of a trench.

E. HODGKIN.

THE COMING WEEK'S WORK.

Extracts from a Garden Diary.

January 23th.—Put in cuttings of Tree Carnations in sandy soil in heat. Auriculas are kept free from dead leaves and dry, or nearly so, at the root; but with longer days more water will be given, and soil is being got ready for repotting. Carnations in frames are kept on the side of dryness at the root in the dark weather we have had. Plants are free from disease. All cold-frames are opened fully in mild weather when not raining. Placed Mint and Tarragon in heat for using green.

January 27th.—Before Cinerarias get forward in bloom the plants are vaporised. A little higher temperature when the flowers are opening improves the colour and adds to size of blooms. Light top-dressings of warm soil are given to Cucumbers rather frequently now. Planted a warm, low house with Melons. We usually start with a scarlet-fleshed kind, as the growth is hardier, and we think the fruits set better. We have grown a selection from Scarlet Gem for many years.

January 28th.—Special care is taken with the conservatory now in keeping the atmosphere genial and everything clean and in order, faded plants being removed often and others

brought in. Bulbs and forced things generally are coming on fast now. Made up more hot-beds for Asparagus, Potatoes, Lettuces, etc. Planted Potatoes in early border. Sowed Horn Carrots, Lettuces, etc., under like conditions outside. Planted several beds of Giant Rocca and other autumn-sown Onions.

January 20th.—Tronchøst and mounded a plot of land for Asparagus. We intend planting in rows 3 feet apart and 18 inches between plants. The seeds will be sown immediately singly in small pots, and be grown in gentle warmth under glass till May, and then planted out, watered, and mulched. Planted Peas and Long-pod Beans on warm border. Sowed Basil and Sweet Mirrjoram in pots in heat to gather green for use early. Radishes have been sown on worm border and covered with straw.

January 30th.—Finished potting show and fancy Pelargoniums. Placed a collection of new Fuchsias in heat to induce growth for cuttings. Sowed seeds of Patunias, Verbenas, etc., in heat. Sub-tropicals, such as Castor-oils, Solanums, and other fine-leaved things that require time, have also been sown in a warm house and will be grown on in heat. Trained Peaches on south wall. Put in cuttings of Geraniums of various kinds in heat.

January 31st.—Vines in second house are now breaking, and the weak eyes that are not required have been rubbed off. Peaches have set well in earliest house, and a few of the surplus shoots have been dibbled. Night temperature now 50 degs. to 55 degs. Air given freely on fine days. Water is rather hard, so syringe is not used much, but paths and borders are damped freely when required. Mero Strawberries have been moved to forcing-house.

LAW AND CUSTOM.

THE MAINTENANCE OF BOUNDARY FENCES.

On page 558 (Dec. 20th), in reply to a question about "Trespassing sheep," you say: "If the fence belongs to your neighbour, then it is a question whether your neighbour is bound to maintain the fence against the farmer's stock." Is this correct law? I have seen several reports of actions in the county courts where damages have been used for under similar circumstances, and in each case the judgment has been for the plaintiff. In one or two cases the Judge said: "It need be considered law that the owner of the fence is liable for its repair, and if a neighbour's sheep or cat trespasses and did damage through the bad state of the fence the owner of the fence was liable for the damage, but such is not the law, as every owner is bound by law to fence against his own cattle or sheep." The question is an important one to country residents, and shall be obliged for an early reply.—W. J. S.

The advice given was to inquire whether the owner of the fence was under any liability to maintain it against stock belonging to the occupier of the adjoining land, and the advice was perfectly sound. You evidently assume that the county court judge meant that under no circumstances was the owner of a fence liable to maintain that fence against stock lawfully on the adjoining land, and, if that is your assumption, it is inaccurate, as the county court judge would not and could not mean any such thing. The words you quote may warrant your assumption, but there would be some qualification or reservation in the judgment which you have omitted to mention and which may not have been set out in the report you have seen. Ordinary newspaper reports of judgments are very rarely complete or trustworthy, although the report of the facts of the case may be perfectly accurate and the broad effect of the judgment may be correctly given. The common law rule is, and always has been, that the owner of stock must keep his stock from straying, and if through his default the stock trespass on the land of another and do damage there, the owner of the stock is liable in damages. This is a statement of the rule in its broadest form, but to the rule there are certain exceptions which in practice are found to be exceedingly numerous. The owner of a fence may be bound to repair and maintain that fence against stock lawfully on the adjoining land in various ways, the principal of which arise (1) By statute. (2) By grant or covenant, or contract. (3) By prescription. To deal with these separately: (1) Where the obligation is statutory. A familiar example is the obligation upon railway companies who are bound by the Railway Clauses Consolidation

Act, 1845, and by their special Acts, to make and for ever maintain fences against the stock lawfully upon the lands adjoining their railways. There are other companies and corporations and owners of undertakings similarly bound by statute. There is another class of statutory obligations which is of even greater importance to the ordinary landowner. A large part of the country has been enclosed under the old Enclosure Acts, and these require that the several allotments awarded thereunder should be fenced and ditched by the allottee or other person or persons directed so to do by the Enclosure Commissioners, and that such fences and ditches should be for ever afterwards maintained by such allottee or other persons and their successors in title. (2) Obligations by express grant or covenant. There are many cases where land has been sold or granted, and it has been an express condition of the grant or sale that a certain fence (or fences) shall be erected and for ever maintained by the grantor or the grantee (as the case may be) and by his successors in title. Or it may be that the condition was that certain existing fences should be for ever hereafter so maintained. Covenants of this kind are often inserted in conveyances, and are, of course, binding upon the covenantor and his successors in title. Then, too, what may be called an obligation by a simple contract may arise, perhaps binding only upon the parties themselves, and not upon their successors. A familiar example of a common obligation by contract arises where two persons hire adjoining lands under the same landowner, and the dividing fence belongs to the land of one of them. If both tenants enter into contracts with their landlords to keep in proper and efficient repair all the fences on the lands let to them, the contract ensures also for the benefit of the tenants, and the one who takes the land with the dividing fence is bound to maintain that fence against his neighbour's stock. This proposition has been doubted, but it has been upheld by more than one county court judge in cases where this has been the issue between two parties. (3) Prescriptive obligations. These are comparatively rare and are difficult to prove. Shortly put, it may be said these can only arise where the owner of a fence does not require it for the purpose of his own stock, but has maintained it for at least twenty years for the benefit of his neighbour, and has from time to time during that period repaired the fence at the request of his neighbour.

Sufficient has now been said to justify to the full the advice given on page 558, to inquire as to the liability. For instance, it may be that the garden in question formed part of an allotment allotted under an enclosure award, and the very fence through which the sheep passed may have been directed to be for ever maintained by the allottee and his successors in title. If so, the occupier of the garden is bound to maintain the fence, and not only can he recover no damages from the farmer, but he is liable to the farmer for any injury the sheep sustain in their trespass. For instance, if they eat any poisonous shrubs or plants, and are poisoned thereby, the farmer may recover damages from the occupier of the garden. It may be that the garden originally formed part of the field and was sold off by a previous owner, and the purchaser covenanted to maintain a fence between the garden and the field. This binds the present owner and occupier of the garden. And if neither of the positions just instanced arises, but, say, thirty years ago, the land where the garden stands was ordinary land, and the owner sold off a building plot, and the purchaser formed a garden and built a house and erected a fence (or maintained an existing fence), and has ever since maintained a fence between the garden and the field, and has repaired that fence from time to time at the request of the occupier of the field, the obligation arises and will continue. It will be no answer to any action by the farmer that the present owner or occupier has only recently obtained possession, and was unaware of any such obligation; if the obligation exists, it is binding and is perpetual. This question has been shortly discussed in these columns some time ago, but as it is of considerable importance to the many readers of this paper in general, and to the occupiers of gardens in

particular, and there is a very great amount of misapprehension on the subject, it has been fully dealt with on this occasion.—K. C. T.]

A gardener's notice.—I was engaged as a thoroughly experienced working head gardener (one man under me) at 2s. a week, paid weekly, with house, coal, light, and vegetables found. There was no stipulation as to notice, written or verbal. Am I entitled to a month's notice, or to only a week's notice?—ANON.

[The point is a little doubtful, but I think the circumstances do not warrant a week's notice, and if you are dismissed on a week's notice, you may claim three weeks' further pay.—K. C. T.]

Release of mortgage.—Some time ago I borrowed some money, and gave a mortgage of a house and garden; three years ago I paid off the mortgage to the executrix of the mortgagee, and was given in return a receipt stamped with a penny stamp. I am told that I ought to have had a release or reassignment of the mortgaged property. Is this so? If so, what must I do?—J. K.

[Yes, the property should have been reconveyed to you. The omission will not peril your title, as between the executrix and yourself, but it may be of consequence if you wish to sell or re-mortgage the property. You can still have a reconveyance effected, but the whole cost of reconveyance will fall upon you, as it would have done even if it had been effected when the mortgage money was repaid.—K. C. T.]

BIRDS.

Death of Canary (C. Kirk).—This was a case of phthisis, a form of tuberculosis attacking the lungs, in the substance of which small Millet-like bodies of cheesy consistence and of a yellowish-grey colour were found. This disease is often met with in cage-birds as a sequel to liver complaint, and in this case the liver was far from being in a healthy state. A bird suffering from phthisis passes badly through the moulting season, has a dry, husky cough, and shows symptoms of gradual emaciation. There is no cure for this complaint—the patient slowly wasting away. From the dull plumage of this bird it appears to have been kept in an impure, smoky atmosphere. To maintain the health of cage-birds abundance of fresh air is essential, together with the best food and pure water, while a supply of sharp grit-sand should never be omitted.—S. S. G.

BOOKS.

"TREES AND SHRUBS FOR ENGLISH GARDENS."

This volume, which belongs to the "Country Life" Library, is specially devoted to a phase of gardening which has, perhaps, not hitherto had adequate treatment in the numerous garden books that have appeared of late years. At this time of day it appears to be still necessary to teach people that they can have shrubs quite as hardy and vastly more attractive than Laurel and Privet, and, of course, admitting of much greater variety of treatment. With this aim the book may be cordially recommended for study by owners of gardens great and small—in particular those who are responsible for the laying out of public gardens. Not the least useful part of the book is the tables of flowering trees and shrubs suitable for the British Isles. The book is nicely printed and profusely illustrated with reproductions from photographs.

United Horticultural Benefit and Provident Society. The monthly committee meeting of this society was held at the Caledonian Hotel, Adelphi-terrace, Strand, on Monday, January 12th. Mr C. H. Curtis presided. Twelve new members were elected: four of these, however, being over 35 years of age, are elected subject to the production of their birth certificate. Nine members were reported on the sick fund. The death certificate of the late Mr. W. S. Cornford was produced, and the amount standing to his credit in the ledger was directed to be paid to his nominee, Messrs. W. Gunner and T. H. Puzey were re-elected to audit the accounts for the past year.

"Trees and Shrubs for English Gardens," by E. T. Cook & George Newnes, Ltd.

CORRESPONDENCE.

Questions.—Queries and answers are inserted in GARDENING free of charge if correspondents follow these rules: All communications should be clearly and concisely written on one side of the paper only, and addressed to the EDITOR OF GARDENING, 17, Furnival Street, Holborn, London, E.C. Letters on business should be sent to the PUBLISHER. The name and address of the sender are required in addition to any designation he may desire to be used in the paper. When more than one query is sent, each should be on a separate piece of paper, and not more than three queries should be sent at a time. Correspondents should bear in mind that, as GARDENING has to be sent to press some time in advance of date, queries cannot always be replied to in the issue immediately following the receipt of their communication. We do not reply to queries by post.

Naming fruit.—Readers who desire our help in naming fruit should bear in mind that several specimens in different stages of colour and size of the same kind greatly assist in its determination. We have received from several correspondents single specimens of fruits for naming, these in many cases being unripe and otherwise poor. The difference between varieties of fruits are, in many cases, so trifling that it is necessary that three specimens of each kind should be sent. We can undertake to name only four varieties at a time, and these only when the above directions are observed.

PLANTS AND FLOWERS.

Treatment of Chrysanthemums (B.).—It is always best to root fresh plants each year, and the growths now pushing up will give good cuttings. Do not attempt to root them until the middle of next month; and when you have secured sufficient, we would advise you to throw away the old stools. Young plants take up much less room, and are not so much trouble.

Ammonia (Follow).—The various preparations of the kind you refer to would certainly be of some benefit, as they would supply ammonia, which has a good effect on the foliage of plants; but they are sold for household use, and are naturally dearer than would be ammonia in forms equally suitable for plants. You had better buy a little nitrate of soda or sulphate of ammonia, or some of the proprietary manures sold for the use of plant growers.

Azalea indica (Church Stretton).—Six choice single scarlet-flowered Azalea indica are: Stella, orange-scarlet; Flambéau, crimson; Countess of Beaufort, vermilion; Eugene Mazel, orange-scarlet; Duchesse Adélaïde Nassau, flamed scarlet; La Victoire, orange-scarlet. Six choice single white-flowering varieties are: Louise Vervane, early flowering; Princess Alice, pure white; Konigen der Weissen, alabaster-white; Mlle. Marie Planchon, very large flower; Mlle. Marie Lefebvre, pure white; Mme. Hermann Seidel, very large and handsome.

Fuchsias, pruning (Prior).—We presume your plants are in pots, and that they are underneath the stage and getting but little water. Leave them thus until early in March, when they may be pruned hard back, and after standing a day or two be placed in a temperature of 55 degs. Here, with an occasional overhead watering, growth will soon move, when the supply of root moisture may be slightly increased. They may be putted on when growing freely, taking care not to overwater until the roots have begun to run freely.

Potting Lilliums (Flora).—Pot the bulbs as soon as you can get them. Drain the pots well, and about three parts fill them with a mixture of light fibrous loam, peat, well-rotted manure, leaf-mould, and some coarse sand. Cover the bulbs with 3 inches of soil, which should be fairly moist, as no water must be given after potting. Place the pots on a hard ash bottom, and cover with a good thickness of leaf-mould or Cocoa-fibre. When the plants have made about an inch of growth remove them to a sunny greenhouse, and water sparingly for a time.

Mossy wall in house (A.).—If your Cucumbers house is now empty, you can burn it in, when close shut up, sulphur dusted freely over red-hot cinders, but the moment it is laid on the fire you must get outside. If the house be close shut for twelve hours, everything living in it, vegetable or insect, should be killed. If you may apply whitewash made with water in which soft soap and soda have been liberally mixed. The whitewash should, however, be dabbed on whilst boiling hot, if possible. We fear, however, that the wall has not had any damp course of slate put into it, and that if you kill the Moss for a time, it will soon grow again.

Tulips (A. R.).—The cause of the flower-stems of your Wouvenman Tulips failing to lengthen out is owing to your having forced them into flower rather too early. Had you allowed them more time for development by bringing them along more gently all would have been well with them. If you require Tulips at this time of year, select only the very earliest flowering or forcing varieties another season, such as the Duc van Thol varieties and others. Wouvenman is a splendid sort, and is what may be termed a midseason flower, and not suited for hard forcing.

Cineraria leaves, insects in (M. E. B.).—Your Cineraria leaves have been attacked by the Marguerite Daisy-fly, which burrows in the leaves of these Daisies, Cinerarias, and other composite plants, and feeds on the inner surface. When many leaves are attacked in this way the plants are not only rendered unsightly, but they also suffer in health. The best way of destroying this pest is to cut off the infested leaves and burn them, or, if the attack has only just commenced, to pinch the leaves where the grubs are. Spraying with an insecticide assists little, as this would not reach the grubs, but if done at the right time it might probably prevent the flies laying their eggs.

Arum Lily decaying (A Reader, Lymouth).—We can only surmise that the stem has been in some way injured in its early days, and the present decay is the natural outcome of the developing growth. Had you sent us a plant we could probably have arrived at something more definite. It was quite correct to pot it in September, and the subsequent treatment so far as stated appears correct. But there is a much more definite cause

for an injury so great and so unusual, and if many plants are so injured we would like to see a specimen as complete as you can. You say nothing of the temperature in which the plants are grown. If the plants have never been in a lower temperature than 40 degs. this is not the cause of failure. Much wetness at this low temperature would not be for good, however. We imagine the etou is have been injured in some way.

Good Cactus Dahlias (J. Casswell).—Twenty good varieties are: Freedom, crimson-scarlet; Mrs. A. F. Perkins, sulphur-yellow and white; Mrs. Mortimer, salmon-red; Mrs. Hobart, orange and salmon; Richard Dean, vermilion; Mrs. Edward Mawley, fine yellow; Clarence Webb, bronze-red; J. H. Jackson, crimson-maroon; Clie, creamy-salmon, etc.; Columbia, vermilion, with white tips; Gen. Buller, velvet crimson, white tips; Artus, dark apricot; Vesta, fine pink; Imperator, ruby-crimson; Cheals White, ivory-white; Fighting Mac, fiery crimson; Mrs. H. J. Jones, scarlet, edged cream; Kingdove, pink-fawn or dove colour; Lord Roberts, white; Eclipse, sulphur-yellow; Arachie, centre white, petals margined crimson; Feuillet, salmon-pink; Keyne's Walle; and Lady Penzance, purest yellow.

Gazania ringens (W. W.).—This is only hardly enough for our summers. It is most useful on warm soils, and should always be placed in open sunny spots and among dwarf plants. Cuttings strike freely in a cold-frame in August, but later require bottom-heat. Unless struck very early, spring-struck plants are almost worthless, so that it is best to put in the stock in August and let them stand in cutting-pots till potting-off time in spring. They will then come well into flower when put out in May; whereas, if they are topped for spring cuttings, both lots will be small and late. Short young tops should be used for cuttings, and may be inserted pretty thickly in the cutting-pots. When established, they must be just protected from frost, and kept in dry, airy quarters. If kept warm they grow too much, and are in spring poor, lanky plants that can hardly be handled; but cool, airy treatment keeps them short and sturdy.

TREES AND SHRUBS.

Planting Privet (H. B. Smith).—You can plant it at any time now when the weather is open.

Mistletoe (P. J.).—You should sow the seed at any time when ripe—say, from February to April, according to circumstances. Put the seeds just under the bark on the underside of the branch of the Apple-tree on which you wish to grow it, or press them on the bark (on the underside), and protect them from birds. Grafting may be carried out in May. Most failures are due to late sowing seeds and to neglecting to afford protection from birds, which are very fond of the seeds.

Transplanting Jasminum nudiflorum (Ben).—Given good open soil, the sooner your Jasminum is transplanted the better, though in the event of frost you must wait till it is all completely cleared away. When transplanting, the very strong shoots may be shortened, but do not cut the plant back too hard. Cotonaster microphylla is a very desirable subject for clothing a wall or fence of the height you name, and its dark green leaves form an admirable setting to the winter Jasmine, but it is a slow-growing plant, and we think that probably the Fire Thorn (Crataegus Pyracantha) would suit your purpose best. The bright red berries of this Thorn form a beautiful autumn and winter feature, and afford a marked change from the golden flowers of the Jasmine. Cotonaster microphylla is naturally of a creeping or spreading habit of growth, and we secured to the wall or fence that it is intended to clothe. The Penzance Sweet Briars in the position named cannot fail to please.

FRUIT.

Table Apples (Church Stretton).—Six best varieties of table Apples, to grow as espaliers, 800 feet above sea level, are Kerry Pippin, Red Ingaltrie, Cox's Pomona, King of the Pippins, Adam's Pearmain, Court Pendu Plat.

Vine resting (B.).—In asking how long a Vine should be allowed to rest, you ask a question that has considerable interest. We know, for instance, of houses of Grapes kept hanging until March, the glass being covered by sheets to exclude the sun's rays, and new growth has begun when the entire crop has been cut. It is hard to understand where the rest comes in there. If you have tender plants in your greenhouse you must keep up a temperature of from 45 degs. to 50 degs. of warmth. If you have none, then throw open the house when the weather is open, just closing it in very hard weather. Fire up a little at night early in March, and then start the Vine generally.

Mildewed Grapes (F.).—If your vine is heated by pipes or brick flue, get milk or soft-soap solution, stir into it flowers of sulphur, then get the pipes or flue hot with a fire, and when so heated well wash the pipes or brickwork with the mixture, kept well stirred; then, so soon as done, shut up the house close for twenty-four hours. Also prune your Vine hard back to good buds near the main stem; then well wash the stems with a soft-soap solution, and whilst damp dust the wood thickly with sulphur. Well wash all the brickwork, throughout clean glass, and, if possible, paint wood work. Have all the trimmings burnt. Next spring and summer, should mildew appear, heat pipes and wash with sulphur-wash, as advised. This is cleaner and more efficacious than dusting the Grapes and leaves with sulphur.

Vine dressing (A.).—It need not be a matter of great necessity do not think of starting your Vines into growth until February. If you do so now, you will have the growth, leaves, and bunches developing in the duldest of weather, and that will cause them to be weaker than if started fully a month later, as the days will then be lengthening and the sun will be getting power. Gishurst-compound is a capital dressing for Vine-roots, but we advise adding to it some clay and paraffin paste. Filling that, put 2 lb. of dry clay to 1 lb. of paraffin, into a tin, and add 2 lb. of Gishurst-compound and make the soil absorb it. Then add 2 lb. or so of Gishurst-compound and some warm water, and well mix the whole, painting the Vine-rod well with a half-worn paint-brush, but not dressing the eyes or buds; wash these carefully with soapy-water only. You can mulch inside border if you like to help feed the roots, but a good mulch will do more good after the Grapes are

thinned. A good soaking of water now may do much good inside, but not outside.

VEGETABLES.

Improving dry land (W. H. Airey).—Salt must be very sparingly used on garden soil, as otherwise it would become harmful to crops. You may strew about between rows of any vegetables about 3 lb. of well crushed salt per rod, applying it when the weather has become warm. If applied in the winter or spring it is to make the soil very cold. But your best remedy is to lay with a chisel subsoil, in throwing out the top soil from a trench 18 in. wide and 12 inches deep, well breaking up the chalky stratum 10 inches deep, then adding a dressing of well decayed and wet manure, especially cow manure, and throwing on to that the next top spit of 12 inches deep and 2 feet wide, breaking up the bottom of that trench, manuring it, and serving all the rest of a breadth of ground in the same way. On ground so treated crops would endure drought for longer than if it were only just dug. If, after crops were well up, and had been thoroughly hoed between to kill weeds and loosen the surface, you could then give a mulch or coat of manure, very much indeed would be done to help retain moisture in the soil during the summer.

SHORT REPLIES.

A. Wright.—Soil to hand quite dried up; we could not find any worms.—Prior.—The only thing you can do to get the bushes.—Cromford.—Sorry we are unable to trace the article to which you refer.—Constant Reader.—You will find the article you refer to in our issue of Dec. 15, 1891.—Geo. Clark.—Apply to the Economy Fencing Co., Billiter House, Billiter-street, E.C.—F. F. Hayes.—We should say that "Hobday a Villa Garden," from this office, price 6s. 6d., would answer your purpose. We know of no books dealing specially with the subjects you mention. If in doubt, we are sure glad to help readers. Kindly read our rules as to correspondence.—Dudley.—Yes, the Aspidistra fern. You will find the flowers on established plants just on the surface of the soil.—T. S. R.—Why not try anthracite coal, which is lasting and good? You must have, however, good draught in your furnaces to burn this. If your house is large we would not advise the use of potatoes.

NAMES OF PLANTS AND FRUITS.

Names of plants.—W. A. Birks—1, Cypripedium villosum; 2, Flower too shrivelled up; please send fresh bloom.

SWEET PEAS.

Aberystwyth, March 9th, 1902: "Mrs. E. P. has won the FIRST PRIZE with your Sweet Peas at the Aberystwyth Show against great competition. Mrs. E. P. also won FIRST PRIZE for best Garden Bouquet with your Sweet Peas."

All carefully hand-picked, new, and English grown.

THE HORT. CO.'S SPECIAL LOW OFFER!

BEST AND CHEAPEST IN THE TRADE. Purchase by weight just what you require—made more economical than collect orders of so many seeds.

3s Carriage paid on orders of 1s upwards. 3d. per ounce; 2d. per half-ounce.

- Alice Eckford, cream & white
- Anora, orange-salmon
- Bianche Barpes, pure white
- Boreton, deep maroon
- Butterfly, white & lavender
- Cass. Aberdoon, white & pink
- Cass. Radnor, mauve & white
- Chancellor, orange pink
- Crown Jewel, rose and cream

VEGETABLES.

EARLY PEAS.

It is the ambition of every owner of a garden to have Peas ready for gathering as early in the season as position and climatic conditions will allow, and to achieve which it is necessary to sow the seed during the present month. The weather, unfortunately for those who cannot raise the seed under a frame or cold-pit, will not always allow of the seed being sown outdoors during January, and the only thing is to wait till a favourable opportunity presents itself, and then sow without further delay. On the other hand, if a pit, frame, or a Peach-house or viary that is resting is at command, then the seed can at once be sown. This may be done in various ways, either in pots and boxes or on turves, the first and last methods being preferred by me. Five and six inch pots are suitable sizes in which to sow Peas. Boxes should not be more than 6 inches in width and about 2 feet in length, and made so that one if not both ends can be detached, to allow of the plants with the mass of soil about the roots being easily slid out into the drills when planting time arrives. Turves must be cut specially for Pea sowing, and should be of a uniform thickness of not less than 3 inches, 1 foot in width, and 3 feet in length. Three drills, one down the centre and one near to the outside of each turf, should be scooped out to the depth of 2 inches with a trowel. In these drills the seed should be sown thinly and covered with a light, rich compost. For pots and boxes the latter should consist of two-thirds loam, and the remainder equal parts leaf-mould and spent Mushroom-dung. Five sound seeds will be an ample quantity to sow in each pot, and with regard to the boxes and turves, sow them also in much the same proportion. If the compost is moist, water will not be required for some few days, and the position the pots, boxes, or turves are placed in, so long as it is quite cool, will not signify much until germination takes place, after which they must have all the light and air available to ensure dwarf sturdy growth. As soon as the plants need support, place pieces of partially worn-out Birch brooms round the pots, and on either side of the drills, as the case may be, and this should suffice if they are given quite cool treatment, and afforded plenty of air on every favourable occasion until they are planted out. When sowing on turves is adopted, it should be remembered that each turf at planting time is cut up and divided into three strips, each having a row of Pea plants in it. One turf will, therefore, furnish enough Peas to plant a row 3 yards long, and this should be taken into consideration when calculating the number of turves required. The outdoor sowing ought to be done in the warmest spot in the garden, such as a raised border facing due south, covering the seed with some fine, dry soil if the staple is at all heavy or adhesive. As regards the distance apart at which the drills should be, this will be governed by the height of the variety selected, and whether the ground is to be cropped between

them or not. In the latter case let the Peas stand 6 feet asunder, and then two rows of early Potatoes may be planted between, or the ground can be utilised for early Spinach, Lettuces, Shorthorn Carrots, Early Gem and Milan Turnips, etc. If the plot is to be devoted to Peas alone, allow very dwarf sorts, such as Harbinger, 18 inches between the rows, and the taller ones from 3 feet to 4 feet. A. W.

ASPARAGUS.

WHERE home-grown crowns are extensively forced, the gardener must annually sow as well as plant a quarter to meet the demand, and as the preparation of the ground is more than half the battle, no pains should be spared to get this in good heart by the time planting time comes round. This choice vegetable requires an open, sunny spot having a dry sub-soil, artificially so, if not naturally, as, if much water is allowed to settle about the roots during the resting period, many of the said roots die away, and the result is, little or no Grass of any value. Asparagus will grow in almost any soil, but that which suits it best is good loam, not too retentive, with abundance of farmyard or stable-manure well incorporated with it, and the ground trenched from 2 feet to 3 feet deep, working in a good percentage of manure at the bottom, and again at 18 inches from the surface. If artificial drainage is necessary, place at the bottom of each trench 6 inches of garden refuse, such as Broccoli and Cauliflower-stumps, fruit-tree prunings, etc., and, over this, a good layer of long, strawy litter before returning the soil. Where the soil is stiff, it should be ridged so that frost and wind may pulverise the same by the time it is necessary to work it down.

PLANTING is best done towards the end of March or early in April just as growth is getting active, setting out the plants 1 foot apart in rows running north and south 2 feet asunder, taking the precaution that the roots are not allowed to get dried up while the work proceeds, and that no injury is done to root or growth when lifting, which must be performed with a five-pronged fork. Drills 4 inches to 6 inches deep should be got out for the plants, making the side nearest the line perpendicular, to rest the crown of the plant against, and evenly spreading out the roots, keeping the crown 2 inches or 3 inches below the surface, and making the soil firm about the roots with the foot as the work proceeds, finally raking over the surface and cleaning up the alleys. One or two-year-old crowns are the best for planting a permanent bed, and no produce should be taken from them until they have finished two seasons' growth, neither must they be lifted for forcing under that time.

SOWING THE SEED.—This may be done towards the end of February if the soil is in working condition, and where there is plenty of ground at command it may be sown direct into the permanent bed, dibbling in three or four seeds together 1 foot apart, retaining the strongest seedlings as soon as the little plants can lie hold of for thinning. The rows should be 2 feet apart as for planting. The seed may also be sown in drills 1 foot apart on

a sunny border, and thinned out to 3 inches apart, to be transplanted next spring. Crocker's Colossal is as good as any, and is still largely grown. EAST DEVON.

NOTES AND REPLIES.

Green Cape Broccoli (p. 507).—I have grown this for many years, and shall again this. I always get my seed from Italy, then you can rely on it being true. I find on many plants you can get side Broccoli heads, only smaller than the centre one. In my opinion the flavour is much more delicious than in the ordinary English Broccoli. The leaves are of a dark blue tint, the flower the same, differing in this respect from any other kind. From seed sown in early part of March I cut at Michaelmas. The flower should not remain till frost. Being a tender kind it is of little use afterwards. The Italian name is *Violetta de Navidad*.—E. VUKES, *Kingsworthy*.

Supplying family with vegetables.—Would it be possible, in a kitchen garden of 1 acre, to grow enough Potatoes—as well as other vegetables—to supply five people all the year round? Please tell me how much ground to give up to the Potatoes, and how much seed to use to a rod? I am told that Duke of York and Myatt's Ashleaf do well here, and think of getting Up-to-Date and the Crofter as well. Do you think that they would do well on this soil, which is mostly of a light, loamy nature, or will you recommend others instead? What proportion should I have of early and late kinds?—BLUE LIAM.

[No exact answer can be given to the question as to whether a family of five persons can get a supply of vegetables all the year round from half an acre of ground. So much will depend on the fertility of the soil, the way cropped and cultivated, the nature of the season, and the vegetable requirements of the people. But, all the same, we think that such an area of ground should suffice for the purpose, because if well trenched and manured, then kept freely cropped, the produce of half an acre of ground can be considerable. Potatoes, to have a supply all the year, or nearly so, should occupy fully one-third of the ground, or say at least 30 out of the 80 rods. If you could obtain so moderate a crop as an average of two bushels of good tubers per rod, that would mean 60 bushels—a large quantity. But to obtain such a crop you must grow but few of the early Ashleaf section. If you plant of these Duke of York and Myatt's Ashleaf, you would need 1½ pecks of tubers per rod, and if large ones be planted, then fully 2 pecks per rod. These plant in rows at 2 feet apart; also plant two rods with Beauty of Hebron or Early Puritan, both early and heavier croppers; then six rods with Windsor Castle, and the remainder with the Crofter and Up-to-Date, as you suggest. These last should be in rows fully 30 inches apart. Your soil ought to grow good Potatoes, the varieties named doing well. The rest of the ground you would have to apportion between Peas, Broad, Dwarf and Runner Beans; various roots, such as Carrots, Parsnips, Beet, Onions, Leeks; also Cauliflowers, Broccoli, Cabbages, Winter Greens of diverse descriptions, Rhubarb, Seakale, Asparagus, Herbs, Marrows, Tomatoes, etc.; all needing judgment in the quantities sown or planted. In all these matters a study

of the columns of GARDENING ILLUSTRATED, under the head weekly of "Garden Work," should render you valuable help in the cropping.]

TREES AND SHRUBS.

THE SWEET PEPPER BUSH (CLETHRA ALNIFOLIA).

This North American plant, introduced to British gardens in 1731, although a very ornamental, perfectly hardy, and free-growing shrub, reaching a height of from 3 feet to 5 feet, is rarely seen unless in choice collections in our large nurseries and hotanic gardens. The flowers, which are white and oppressively fragrant, are produced in short racemes at the tips

The Sweet Pepper Bush (Clethra alnifolia). From a photograph by G. A. Champion.

of the branches early in September. It is a moisture-loving plant, and should therefore be grown in a damp spot in the bog garden. It will also succeed fairly well in rather damp loam, to which a small quantity of leaf-mould has been added, and given a sheltered position. Pruning is important; indeed, to grow this Clethra well, it should be cut hard back at stated intervals.

NOTES AND REPLIES.

Propagating the Mistletoe.—In answer to "J. C. Usher," page 611, January 17th, I have large quantities of Mistletoe growing on Apple and Thorn trees. The berries will be ripe in March or April. I shall be able to supply any quantity of berries for propagating.—TAMMÁS TERLEV, Postmaster, Rochester, Staffs.

Shrubs for sandy soil.—I have purchased a plot of land on a hill, part of which is a sand-pit, and in fact, the ground is nearly all sand. Would you kindly advise me through the medium of your paper what trees and shrubs will do well in such sandy soil, as I wish to

plant the garden almost entirely with trees and shrubs?—PERFLEND.

[Many flowering shrubs and trees do well on sandy soil, better than in heavy soils. The Scotch Fir and Pines also do well, with the exception of the Spruce, which requires a damp soil.]

A supposed Desfontainea.—I am greatly pleased that your correspondent "W. T." has taken up the question of my friend's supposed "Desfontainea." I think there can be no doubt that "W. T.'s" explanation is the right one, and that the shrub is an Osmanthus. What he says tallies in every point with what I saw myself in the churchyard at East Budleigh, 2 miles inland. I shall not be there for some time, but shall be pleased to send a spring shoot from the shrub later on, when I daresay "W. T." will not have forgotten the incident. "Desfontainea spinosa"

bark all around the cut surface endeavours to heal the wound. The Stockholm tar, to a great extent, protects the wood from further decay, and also prevents the water or any fungus settling there. We also noted that in some had cases the wounding had been filled up with cement first—notably an old Crataegus, where a large branch had well nigh split the stem of the tree right down the centre, and yet the tree looks the picture of health, and is full of flower every summer. Fruit-trees having very large branches broken off may be treated in like manner. In the case of the Pines insignis, endeavour to train up a new leader by placing a stout stake to the main trunk, but making sure it does not cut the bark by placing between the tree and stake stout pieces of canvas or gutta-percha, and then, if the tree is not too old or the branches too stiff or brittle, gently pull in the nearest branch on the top. We have known this to be successful in several cases.]

Erica mediterranea hybrida.—This comparatively new yet most delightful hardy Heath, ushers in the New Year with its masses of rosy-purple blossoms, and till they expand again about Christmas next, there is little if any time without some members of the Heath family contributing to the floral display out-of-doors. Following on the just-named forms come the pretty little Erica carnea or herbacea, and its white variety (alba). Long before these are over we have the typical Erica mediterranea, with the larger-growing Erica codonodes, or Insitanica as it is often called. The St. Daboc's Heath (Dabecia polifolia), unfolds the first of its urn-shaped rosy-purple blossoms by the month of May, and maintains a succession till the autumn. The white variety is equally free-flowering. After this comes the Grey Heath (Erica cinerea), with its many varieties, usually at their best about mid-summer, while the latter part of August and the early autumn see the greatest glut of all, there being the Ling, or Heather (Erica vulgaris), with its varieties innumerable—Erica ciliaris, Erica tetralix, Erica vagans, and Erica multiflora. Considering the great beauty of the Heath family and the fact that the members of it will succeed in many places unsuitable for most shrubs, it is surprising that we do not see them more generally planted.—X.

How to improve faulty Yew hedges.—It frequently happens that Yews, when planted to form ornamental hedges with, do not give such satisfaction hereafter as they should do, through the bushes failing to fill up and forming a perfect screen from the base upwards. This invariably arises from want of careful selection of the bushes at planting time, for if they are well furnished with branches, as they should be down to the ground line, the objection mentioned cannot occur, and the hedge will not present a gappy appearance, such as it does when unsuitable plants are used. By the latter is meant drawn or attenuated bushes which have got into this condition through being too crowded in the nursery lines, and as a natural sequence have lost a goodly portion of their lowermost branches. Such are most unsuitable for hedge planting, and if used, no matter how good the soil and situation may be, it takes years to remedy the defects. Where hedges have been found with bushes of this description, the only way out of the difficulty is to grapple with it as soon as the growths are of sufficient length to allow of their being manipulated and drawn to where required to fill up the vacancies. The most convenient branches should, as a matter of course, be utilised, securing them with tarred twine to short stakes driven firmly into the ground. The hedge should be commenced with at one end and gone thoroughly through, first on one side and then on the other, throughout its entire length, and if the branches are secured in the manner indicated, they will become set by the time the twine and stakes decay and not move out of position again. If this is carefully and methodically carried out, the hedge will in time present an unbroken surface or face, but, of course, it is much better to employ well furnished examples at the outset, and obviate the necessity for resorting to the training and tying of branches to hide up inequalities.—A. W.

does flourish here. I have seen a large and beautiful shrub of it in flower on a friend's lawn, and not near the sea—perhaps half a mile from it.—M. A. H., B. Salterton, Devon.

Decay of tree-trunk.—I should value your opinion on following: 1. Best method of arresting trunk decay in forest trees, fruit trees? I have a handsome Liriodendron tulipifera which is holed by decay, result of branches having been cut off, and water lodging in apertures so created. 2. A Prunus insignis had leader recently broken off, and its gum persistently exudes. Can tar, paint, or anything be applied to effectually correct exudation?—INQUIRY.

[We remember, when visiting Bicton, Devonshire, a few years since, seeing in the Arboretum several of the Conifers whose branches had been broken or cut off. The wounds, after being smoothed over with a plane or chisel, were painted over with Stockholm tar, care being taken that it did not come into contact with the bark. If these wounds are examined once or twice a year it will be noted how the

PLANTS AND FLOWERS.

OUTDOOR PLANTS.

ECHINACEA PURPUREA (SYN. RUDBECKIA PURPUREA) AND ITS VARIETIES.

This is a native of Louisiana, and has been known since 1799. From seed several interest-

take is made is that so many of us want bloom as long as possible, and when plants are spent out we begin to think of seed. Seed harvested under such conditions is seldom, if ever, satisfactory, and if one is desirous of saving one's own seed, those particular plants should be reserved for the purpose. I think, however, for a moderate-sized garden it is best to procure a fresh supply every year from a good source. My experience is that it is cheapest in the end.

like flowers, is indeed an attractive plant, and having, like the *Gloriosa*, a prohemisile tendril to every leaf, it climbs with great facility. My old friend and former neighbour, Anderson Henry, of Clematis fame, had it growing over the front of his house for years, and the seeds dropped on the border underneath and vegetated freely. He gave me seedlings to train round my dining-room window. I should think there could not be much difficulty in procuring seeds from Peru or other parts of South America. I well remember Mr. Henry speaking of some florist friend going to the Andes and remarking, "Yes, he is off to the land of the *Mutisia*." Perhaps some of your readers may be able to inform me how seeds of this pretty climber can be obtained? I once saw near Edinburgh quite a square yard of a house wall a mass of these flowers.—A. B. HERBERT, *Morden, Surrey.*

Rudbeckia (Echinacea) purpurea.

ing forms of this plant have been obtained, these offering some variety in colour, and, in fact, a sensible improvement on the type. Even prior to these very distinct gains the two following forms were known—viz., *E. p. intermedia*, with flowers more displayed, rounder and more tufted than those of the type; and *E. p. serotina*, a rough-stemmed form with narrow florets. Of the new varieties, we give special mention to the two following:

- E. p. ROSA ELEGANS*, a hardy kind, bearing many blooms of a handsome light rose colour, the florets sometimes edged with yellow, and
- E. p. ATRO-PURPUREA*, with flowers deep red-purple in colour. We think that as the result of hybridisation and intelligent selection other variations will shortly make their appearance.

Like all Rudbeckias, this plant requires, in order to thrive, a good, deep, and well-drained soil, and not too much exposure to the sun. It is useful for borders to shrubberies, and looks well also in isolated tufts of three plants on the lawn, or it can be grown in the kitchen garden for cutting. As a cut flower it is a welcome addition to the plants, of which there are still too few available for this purpose. It is increased by division in autumn, or preferably in spring, and from seed. Sow the seed as early as May in heated frames if flowers the same year are desired, or in June, and preferably in cool-houses, and then transplant to the nursery for planting out in the autumn, or rather in the spring. This species is naturally variable, and among seedling plants of it there is much diversity of colour, varying from rose to purple. One may, therefore, expect to see varieties of this handsome plant occurring naturally.

JULES RUDOLPH (*Revue Horticole*).

ANEMONE JAPONICA QUEEN CHARLOTTE.

FOR many years the forms of *Anemone japonica* were three, and gave no sign of any increase in their numbers. Within the last few years, however, the three old kinds, the red, white, and pink, have been materially augmented, and in the pink and white forms more particularly. It is with the former of these two colours that we are now concerned—viz., the pink, which is distinguished by the name given above. Not only is this a novelty, it is a decided gain to garden plants, and to autumn flowers in particular. The variety has been before the public now for a year or two, and like all the forms of this race, the plants require to be fairly established before the full value or beauty is seen. It has been so with the present kind, which in not a few instances attained somewhat of its full beauty in the past year. Compared with the others of this shade of colour, *Queen Charlotte* surpasses them all, the blossoms being much larger, the petals more numerous, and more distinctly obovate and rounded at the margin. The colour is a good rose-pink shade, the handsome saucer-shaped blossoms about 3 inches across, and produced as freely as in the other kinds. The plant is very vigorous in its growth, and with liberal treatment will attain from 4 feet to 6 feet high. This worthy addition to good garden plants received the award of merit from the Royal Horticultural Society in October last, when it was shown in excellent condition.

E. J.

Anemone japonica Queen Charlotte.

Saving seeds.—Whether after taking everything into consideration there is very much to be gained in saving seeds, and especially flower seeds, is a question, I suppose, upon which there will always be a difference of opinion. Gathered early, there are some flower seeds one may save.

The Mutisia.—It has often surprised me that I never see in any nurseryman's catalogue a notice of the *Mutisia*, either as plants or seeds. In the "English Flower Garden" three species are mentioned, but I am familiar only with one, *M. decurrens*, and this, with its bright orange, star-

GARDEN EDGINGS.

I AM not an admirer of flowering plants as edgings for garden paths could we but find some hardy evergreen plants that in blooming did so for a long season, and in so doing did not leave behind unsightly dead flowers and stems. A Box edging is decried because it always needs clipping once a year; but where is the flowering plant that does not need to have its dead flower stems cut over once at least in the year? The complaint that Box edgings harbour vermin is true equally of all edging plants, whilst those which spread and grow close to the ground are worse in that respect than Box is. The former are close growing and spreading, the latter is narrow, neat, and relatively does not offer any great amount of cover for slugs and similar pests. Of living or plant edgings the three best are turf, Box, and Ivy. Turf edgings should be proportioned to the width of the paths

and borders they divide, but should never be less than 8 inches, so as to enable a narrow lawn-mower to be run over them once a week. If edged with shears once in two weeks, such edgings are neat, neutral, and give little trouble. Box edgings should not exceed 4 inches broad or 5 inches in height, and instead of having a flat top, should have the sides bevelled, so that the top forms a somewhat sharp ridge. No edging can well be

neater than is this, and it is not excessively stiff or formal after the summer growth has been made. Ivy should be of any small-leaved, close-growing variety, though none is better than the common Wood Ivy. This

needs some pegging into position during its earlier growth to get it well into line, but once growth is good, only an occasional side trimming is needed to produce a very pleasing edging that should be from 10 inches to 12 inches wide.

Of flowering plants, few are better to make a neat edging than are the Mossy Sedums, such as the green *Lyodium* or the silvery *glaucum*. To have these in good form the soil for the edging should be slightly ridged, the Sedum being in the early spring dibbled into the apex in tiny clumps 6 inches apart. Very soon the clumps extend and touch each other. It is then needful only to chop down the edges with a spade once a year. Such edgings will keep good for three or four years. Next come Mossy Saxifragas, although these do not always make so even a growth. Then comes common Thrift, a charming green-leaved plant, but giving some trouble as the flowers die off, and also in damping off, or otherwise disappearing. Common Pinks are for a long time untidy and need edging hard usually twice a year. A broad edging of any plants when in full bloom is formal, and kills, to a large extent, choicer flowers that may be blooming in the borders. London Pride gives a fairly compact base, but in bloom is very weedy and untidy. Aubrietia and Arabis will also make fair edgings, both needing some trimming of edges and flower stems. Auriculas are far from being objectionable edging plants, especially if the soil for them be slightly elevated. The flowers in decay can readily be gathered off, and the edges of the plants need little trimming. Daisies seldom keep perfect as plants frequently die.

There are other plants more or less suitable. It should be a primary consideration with garden path edging plants that they be fairly enduring, need little attention, maintain a good face, and be generally so far neutral that they do not kill border flowers with an excess of bloom. Of course, to be enduring they must be quite hardy. D.

GROWING ALSTROMERIAS.

Will the Editor of *GARDENING ILLUSTRATED* kindly give me information on the culture of *Alstromerias*? When and where they should be planted—in the open ground or in conservatory?—E. J. STREET.

[*Alstromerias* must have a thoroughly well-drained soil to prevent the tuberous roots from suffering from an excess of moisture. The best place is a south border, or along the front of a wall having a warm aspect, where, if the soil is not light and dry, it should be made so. Dig out the ground to the depth of 3 feet, and spread 6 inches or so of brick rubbish over the bottom of the border. Shake over the drainage a coating of half-rotten leaves or short littersy manure to prevent the soil from running through the interstices of the bricks and stopping up the drainage. If the natural soil be still, a portion should be exchanged for an equal quantity of leaf-soil, other light vegetable mould and a borrow-load of sand should be well mixed. The plants should be procured in pots, as they rarely succeed from divisions, and, once planted, should never be interfered with. Place them in rows about 18 inches apart, and with 1 foot from plant to plant. If planted during the winter, they should be placed from 6 inches to 9 inches deep, so as to keep them from frost; and a few inches of half-rotten leaves shaken over the soil. Should there be any difficulty in obtaining established plants in pots to start with, seed may be had; and this sown in pots or in beds where the plants are to remain. The seeds, being as large as Peas, may be sown 2 inches or 3 inches deep; with three or four seeds in a patch. If well treated, they will begin to bloom at a year old, and if not disturbed will increase in strength and beauty every season. When grown in masses in this way they are very beautiful, as every stem furnishes a large number of flowers, varying much in their colour markings. While growing and blooming they should have occasional watering, otherwise they get too dry, and ripen off prematurely. A good mulching of old Mushroom-dung or of leaf-soil is a great assistance while in bloom. When going out of flower carefully remove the seed-heads, otherwise the plants are apt to become exhausted, as almost every flower sets. In removing the pods do not shorten the stems or reduce the

leaves in any way, as all are needed to ripen the tubers and form fresh crowns for the following year. The stems should therefore not be cut down but die away naturally. Anyone having deep light sandy soil resting on a dry bottom may grow these beautiful flowering plants without preparation; all that is necessary being to pick out a well-sheltered spot, and to give the surface a slight mulching on the approach of severe weather. No trouble is involved in staking and tying, for the stems are strong enough to support themselves, unless in very exposed situations. They are quite worth cultivating for cut-flowers, as they last long when cut. The species in cultivation are:—

A. AURANTIACA (*A. aurea*), a vigorous-growing Chilean kind, 2 feet to 4 feet high, flowering in summer and autumn. The flowers are large, orange-yellow, streaked with red, umbels of from ten to fifteen blooms terminating the stems.

A. CHILENSIS.—This is a quite hardy kind from Chili, with many varieties that give a wide range of colours from almost whits to deep orange and red.

A. PELEGRINA.—Not so tall or robust as the last; but the flowers are larger, whitish, and beautifully streaked and veined with purple. There are several varieties, including a whits one, which requires protection. When well-grown it is a fine pot plant, compact and crowned with almost pure whits flowers. It is called the Lily of the Incas.

A. PSITTACINA (*A. braziliensis*).—Grows about 1½ feet high, each stem being terminated by an umbel of from seven to nine flowers, smaller than either of the preceding, and green and deep red in colour.

Other good kinds are the hardy variable-coloured *A. versicolor* (*A. peruviana*), and *St. Martin's-flower* (*A. pulchra*), this, however, requiring protection.]

NOTES AND REPLIES.

Coltsfoot in garden.—Will you kindly tell me the best way to kill *Coltsfoot* in a garden? The garden is many years old, and nothing has been done to it for years. There is 2 feet of soil above the clay, and there are clusters of *Coltsfoot* roots running on the clay. What will be the best to crop the garden with to make it pay, and get rid of the *Coltsfoot*?—W. J. C.

[The best course would be to trench the ground and pick out all the roots you can. After that keep the plants hoed off severely, especially the flowers, but in any case chop off with a hoe every bit that shows. That will kill it in time. No crop will kill *Coltsfoot*, as being so early it gets the start of crops. There are no other means of destroying it than we have advised.]

Ugly corners.—Many an ugly corner in a garden that for long has been an eyesore, because perhaps the situation is a sunless one and few plants will grow there, may be changed and made attractive if only one goes to work in the right way. Let us take the worst view of the case, and imagine no sunshine ever visits the corner in your garden, which you have given up in despair; there is yet a remedy. Why not try a hardy fernery? You may set about it at once, and so get it into shape for spring, when hardy Ferns can be planted. In country districts, at all events, one may often procure limestone or sandstone at a reasonable cost, and these, placed in desired positions with soil filled in between each, will be suitable for planting Ferns, *Ivies*, etc.—W. F. D.

Perennial Phloxes.—What a beautiful effect herbaceous *Phloxes* have in a border of hardy flowers. When in bloom, too, they remain in good condition for some time, and when cut they are exceedingly handsome; last, but not least, though one does not notice it referred to very often, they have an agreeable odour, a sweetness somewhat resembling the smell of honey. The earliest of them (*P. suffruticosa*) flower in May and June, and are dwarfier than the autumn-blooming sorts (*P. decussata*), which commence to open in July and August. These latter are, however, the showiest, and, indeed, are regarded as a distinct feature to a garden in autumn. If anyone is at a loss to know what to plant for back-row subjects for autumn blooming, I would suggest these, as they give little trouble the year through. Clumps in my garden had

their flowering stalks cut away in November and mulched with stable-litter. Moreover, *Phloxes* are easy to propagate. The best plan is by taking cuttings of young shoots, dibbling them into pans or a bed of sandy soil. This may be carried on any time in the summer, and plants thus procured are much stronger than where propagation is effected by division of roots. If one can spare a frame and make up a bed of leaf-mould and sandy loam, a nice stock of plants may soon be got together for blooming the following year. In planting them out in the garden, one should, if possible, give them a deep soil enriched with rotted dung, as they pay one well for liberal treatment and benefit greatly by a cool bottom, especially in a dry season.—WOODSTOCK.

Sweet Peas.—Questions are often asked as to the best time to sow *Sweet Peas*, but no hard-and-fast rule can be followed, so much depending upon the locality and season. A person in the south of England can, of course, commence to sow much earlier than one in the north, but both can be preparing the ground by digging it over, exposing it to frost, and thus making it as light and friable as possible. Further than this, a stack of well-rotted dung should be got together for use prior to sowing. Last year could not be considered an ideal season for *Sweet Peas*, as they made in many places too much growth at the expense of blossoms in consequence of the wet. Some of mine, sown in March, did not bloom any earlier than seed sown in May.—LEAHURST.

Single Pyrethrums.—Single *Pyrethrums* are preferable to double ones for indoor decoration, for the simple reason that they are lighter, and more varied in colour, some of the tints being soft, and harmonising better with the furnishing of a room. I have this on the authority of a lady who has had considerable experience in the floral arrangements of tables. With this view I agree, as however beautiful some of the double sorts may be, they are clumsy-looking in comparison with the single sorts. Most of us think of growing *Pyrethrums* from division, but seldom think of the less expensive way of propagating from seed. This may be done by sowing in a frame in March, or in beds in the open air in June. Plants raised thus will commence to bloom next year.—TOWNSMAN.

Herbaceous Lobelias.—Will the writer of the valuable and interesting note on herbaceous *Lobelias* in your issue of January 10th, kindly say whether they suffer if exposed to cold wind when the young shoots are coming up?—DALTA.

[Herbaceous *Lobelias* form rosettes of leaves around the tall stems in the autumn. When the flowering-stems are cleared away the leaves of these rosettes, generally of a deep crimson colour, may be seen lying close to the ground. In this condition they remain until the warmer weather in the spring, when the shoots are thrown up. In the severe winter of 1896, when for many weeks the ground was frozen hard, the little leaves of the *Lobelias*, which had only been divided and replanted two months previously, and were totally unprotected, shrivelled, lost their colour, and appeared dead, blooms of Christmas *Roses* in bud and half-expanded lay prone on the hard earth, and even the *Polypody* in the fork of an Elm was brown and withered. When, after many weary weeks of waiting genial warmth returned, the *Polypody's* leaves slowly gathered green, the stalks of the Christmas *Roses* stiffened and stood erect, the buds expanding as if they had not lain in a frozen trance for over two months, and the leaves of the *Lobelias* gradually regained their shining crimson, the plants flowering grandly in the autumn. This proves that herbaceous *Lobelias* can withstand severe frost without injury, while the young shoots of plants that have come through the winter in the open, unprotected, take no harm from the coldest of spring winds.]

Showy town borders.—What to grow to make a flower border in a town showy is a problem that many have to face. In some districts to attempt to grow some of our hardy plants is only fraught with expense and disappointment, but one can do a great deal to brighten up a place by showy annuals. *Godetias*, *Snagdragons*, *Shirley Poppies*, *Mignonette*, *Clarkias*, *Coreopsis*, *Candytuft* cost but little and make a good display. Sow in April, and in the meantime make the soil

light and sweet by turning it over, and, if necessary, adding manure. Town gardens need not be the poor-looking places often seen if only more annuals were sown.—TOWNSMAN.

HERBACEOUS BORDERS.

For many years hardy perennials were almost entirely banished from our gardens, their places being taken by tender bedding plants, which needed the shelter of glass during the winter, and made no display in the open until midsummer was past, after which time they provided flat surfaces of bright colour, mostly in geometrical patterns, for some three months before being finally removed from the beds. When things were at their worst, however, a reaction, chiefly owing to the efforts of the author of "The English Flower Garden," set in, and little by little the value of beautiful hardy plants that required no glass protection during the winter, but when once set in the soil increased in loveliness from year to year, began to be recognised. By slow degrees, for nurserymen, finding that there was no demand for perennials had almost ceased to cultivate

here encroaching over the gravel of the pathway, here showing a glimpse of the edging stone of the border, with a rigid row of glazed tiles or the almost equally stiff bordering line of clipped Box. Edgings are best made of rough country stone, immediately behind which dwarf-growing subjects with a spreading habit should be planted, when they will quickly hide the stones from sight. White Finks are excellent for this purpose, as their blue-green foliage is always pleasing to the eye, and when in flower they are snowy with blossoms whose delightful perfume fills the air. Other good plants for covering edging stones are Iberis, London Pride, Helianthemum, Arabis, Aubrietia, Aronaria montana, Alyssum saxatile, Mossy Saxifrage, and low-growing Sedums. Delphiniums are showy back-row plants, and Hollyhocks, where these are not troubled with the disease, have a fine effect when grouped, the single yellow Althaea ficifolia being a pretty species. Lupines, Galaga, Bocconia cordata, Spiraea Aruncus and S. palmata, Oriental Poppies, and tall Irises, with the more vigorous Starworts or Michaelmas Daisies and perennial Sunflowers in the

colours, they will produce not only a good effect in the garden, but all that can be desired in vases when picked. If not already done, seed should be sown at once, for the plants need to get deeply rooted before the warm weather comes on, and to last in bloom for any length of time the soil must be deeply cultivated and well manured. The best rows I have ever had were prepared like Celery trenches, by taking out the soil one spit wide and two spits deep, filling the bottom with good rotten manure, then returning enough soil to nearly fill the trench, scattering the seeds rather thinly over the surface, and covering so that the top of the row was a little below the ordinary level. Mulching, watering, and staking as soon as the plants are well above the soil are the main points of culture, and the flowers look best if some tops with buds and leaves are gathered with them.—J. G., Gosport.

INDOOR PLANTS.

SEED SOWING.

At the commencement of the new year no time should be lost in sowing a few choice flower seeds. Seeds of a choice strain of Gloxinias should be sown thus early; the young plants thereby raised will with good attention surpass a stock of old hulbs and flower profusely from June onwards to the late autumn. With the splendid selections of these beautiful plants now in cultivation, named varieties are not so much in request, with the exception probably of the pure white kinds. A packet of seed, if divided and sown at intervals of a few weeks, will give an abundant stock, from which selections may be made whilst in bloom for retention another season for early flowering. The object of sowing at two different times is not to guard against failure so much as to prolong the season of blooming. In sowing extra early there is rather more risk of a good crop of seedlings being obtained, but when secured the gain is obvious.

A fair amount of bottom-heat is a great assistance early in the season for raising these and other seeds requiring somewhat similar treatment. I have pipes for bottom-heat running through a propagating pit, overlaid with Coconut fibre resting on slates. By this means a genial heat is secured averaging from 75 degs. to 85 degs. For these and all other minute kinds of seeds I always prefer to cover the pot or pan with a pane of glass, which if cut in the shape of a hexagon will be all the better for round pans. This is much better than confining the seed-pan in a close pit or frame by which a greater amount of atmospheric moisture is precipitated upon the soil, in some cases to form a thin film which may eventually be productive of a minute form of fungid growth. A soil with a good admixture of silver-sand is the best. I prefer it to consist of sandy loam and leaf-mould in about equal parts. A great depth of soil is not beneficial; rather make up well with drains to, leaving a space of about half an inch between the top of the soil when the seed is sown and the glass which covers it. Hardly any water will be needed until the seed has germinated when covered with glass, a good watering having been given previous to the seed being sown. As soon as it is seen that the seeds are germinating, a close watch should be kept that none of the seedlings are lost by damp; a little air admitted during the day will generally counteract this. Seeds of the tuberous-rooted Begonias should also be sown early in January, and those who intend growing Streptocarpus should now sow some of the seed. Both of these just named will succeed well in the first stages under the same conditions as advised for the Gloxinias. If Amaranth seed of a choice strain is not yet sown, no time ought to be lost in sowing to

A Worcester-shire manor-house garden. From a photograph by Mrs. Ward, Chambers Court, Tewkesbury.

them, the old hardy plants resumed their rightful position in the garden, and as they increased in favour, their ranks were augmented year by year by the introduction of numerous handsome hardy perennials from foreign climes, until at the present time, with many hundreds of species and varieties at our disposal, the question is not so much what to use as what to dispense with, but now-a-days, when almost every garden, large or small, has its herbaceous border, or borders, the supply of hardy plants is fully equalled by the demand. Early summer is perhaps the season of the year when the mixed border attains its greatest loveliness, and this is evidently the time that the photograph of the Worcester-shire manor-house garden, here reproduced, was taken. On the right hand a long array of Flag Irises in full blossom stretches away into the distance, while in the broad border upon the opposite side of the path Delphiniums, Irises, and other flowering subjects of various heights present a charming example of informal grouping. The dwarf plants voiling the verge of the path with spreading cushions of bloom and foliage show the proper way of treating the edges of walks. Compare this wavering line of lowly flowers,

autumn, are valuable perennials for positions towards the back of the border, and bright colour may be obtained by the use of Cactus Dahlias and Cannas, which, however, will have to be lifted and stored during the winter. Many of the Campanulas are attractive border plants, among these being C. grandis and C. latifolia with their white forms, C. persicifolia, its white and double white varieties, as well as the semi-double C. p. Moerheimi and Back-house's fine new variety, while the allied Platycodon, P. grandiflorum and P. Mariens, and their white forms are particularly handsome.

Sweet Peas.—These have for some years past had a greater amount of attention bestowed on them than any plant that is annually raised from seed, and the inquiry already for seed for sowing shows no sign of falling off. The number of varieties now enumerated in catalogues is almost bewildering. For specialists they all have their merits, but for the ordinary amateur with a small garden a good mixture will produce nearly all the colours imaginable, and if a good successional stock of these is kept up throughout the season, with a few rows or clumps of pure white, scarlet, and other self

it. The compact variety of the common Musk is easily raised and comes true from seed. If sown early, good plants for bedding out will be had by May. An early sowing of the seed of *Toronia Fournieri* will give a useful lot of plants for flowering in June, even after having had one or two pinchings to obtain stocky growth. The stove Periwinkles (*Vinca alba*, *V. rosea*, and *V. oculata*) should also be sown early to get good plants the same year. Seeds of the winter-flowering *Begonias* of the *B. insignis* and *Knowlseyana* type should also be sown as soon as ripe; this will not be many weeks. The seed-pods in many instances will be already of full size. As soon as the seedlings of these *Begonias* are safe, the older plants may be disposed with to a great extent.

NOTES AND REPLIES.

Fuchsias.—Those who have old plants of *Fuchsias* should, without further delay, lock them up, for now is a convenient time to cut them back, bring them into heat, and propagate from the new growth which will speedily result. Cuttings thus taken will soon root if placed in a warm pit, and can then be put in boxes or potted as desired. Such plants make capital stock, either for the flower borders of conservatories. —LEAHCERT.

Creepers for house.—I have a glasshouse, where a little heat is kept. In the centre it was planted with Ferns, which do well. There are six supports holding the roof, on one of which a *Smilax* grows well. What flowering creepers would you advise for the other five supports? The supports are iron. And when would you plant the creepers? I do not want *Roses*. —W. D.

[You cannot do better than try a *Fuchsia*, *Clematis Indivisa*, *Hydrothamum elegans*, *Pasiflora Constance Elliot*, *Lapageria rosea*, and *Plumbago capensis*.]

Primula Sieboldi.—This *Primula* deserves greater attention than what is usually paid to it, as one may grow it well in an unheated greenhouse. The plants are best potted in November, as in the winter they form strong roots, and are much better shifted than in spring. Where plants are growing in sheltered nooks out-of-doors it is of great benefit to them if a hand-light can be placed over them, and the first spring sunshine brings them into bloom. Plants in pots should be placed in summer on a cool north border. —WOODBRISTWICK.

Bedding plants in winter.—In houses mainly devoted to the keeping of bedding plants during winter there is often a waste of coal, etc., and an unnecessary amount of heat. This obtains largely in amateurs' greenhouses. Only the other night, when the air was mild, a large fire was being kept up in a house where there was no need for one at all, as the plants consisted of *Pelargoniums* and *Fuchsias*, etc., only requiring to be kept free from damp and frost. The leggy appearance in spring of not a few plants is due to this cause alone, and during mild weather keeping the pipes warm to dispel damp is all that is really wanted. —TOWNSMAN.

Swainsonia galegifolia alba.—This, also known as the New Zealand Vetch, is a capital subject for clothing a portion of the back wall of a greenhouse, for planting in an odd corner of a Peach-house, or in similar positions. It may be grown in large pots, but succeeds much better planted out in a border of prepared compost, as it then grows more luxuriantly, and produces its flowers with greater freedom, both the size of the flower and the strength of the spike then being considerably enhanced. It begins to bloom about the beginning of May, and from then on onwards it is seldom without flowers until late autumn is reached. A compost of two-thirds loam and one-third leaf-mould, with a liberal addition of coarse sand, suit its requirements admirably. When in full growth the roots demand an abundance of moisture, and timely attention must be given to the regulating and tying in of the young growths as they become entangled and untidy-looking. During the winter months the plants should be given a thorough rest, consequently but little water at the roots is then needed. Before the plants start into growth they should be relieved of quite two-thirds of the previous season's growth, which makes them break strongly and imparts extra vigour to them. As it is a free rooter it is always prudent to afford a top-dressing of fresh compost each season as soon as the pruning and tying are completed. The flower-spike and blossoms are similar in appearance to those of the Everlasting Pea, but are not quite so

robust. They are very useful for cutting, as they may be employed for bouquet making, dinner-table and drawing-room decoration, with excellent effect, particularly if cut with a piece of stem and accompanying foliage. After the plants have done flowering the young shoots may be used in various ways, not the least of which is in mixing them with cut flowers in vases. If loosely and informally disposed they greatly add to the general effect of any arrangement, and such as it is almost impossible to obtain with the shoots and foliage of any other plant at this season of the year. —A. W.

Ferns and bulbs in baskets.—I am anxious to know when Ferns and bulbs should be planted in baskets and pots to be up in spring, and if they should be put in together or transplanted to the baskets later on? If it is too late this winter, could they be brought on by forcing? —BRAINER.

[A puzzling question, for nothing whatever is said as to the positions the baskets are to occupy. Concerning the bulbs, all thoughts of them may be at once dismissed, as they should have been potted at least a couple of months ago, and if you were to obtain bulbs now they would be too much exhausted from being out of the ground so long to flower in a satisfactory manner. The generally-grown classes of bulbs, such as *Hyacinths*, *Tulips*, *Narcissis*, and such things, should be potted by the end of October, or soon after at the latest, and then stood out-of-doors and covered with coal-ashes or Cocoa-nut-refuse to induce the formation of roots. When they are well rooted the pots should be removed from the covering material and taken into the greenhouse, when the plants will gradually develop and flower satisfactorily. If you desire to have baskets of Ferns in the greenhouse and possess young thriving plants available for the purpose, you can lie the baskets with Moss, so that they resemble a bird's-nest, and plant the Ferns therein, using a mixture of loam and leaf-mould or peat and a little sand for the purpose. This should be done early in March, as the plants will then grow away freely without a check. Again, hanging-baskets may be utilised for a summer display of flowering subjects, as if planted with such things as Ivy-leaved *Pelargoniums*, *Tuberous Begonias*, *Lobelias*, *Tropaeolums*, and such things, they will be very beautiful all the summer if carefully attended to in the matter of water, etc. Young growing plants of these things can be obtained very cheaply in May, when they can be at once planted in the baskets. You will find it a good plan to stand them on the stage of the greenhouse at first, as it is better to allow them to get somewhat established before hanging them up.]

Plants for cool-house.—I shall be obliged if you could tell me the most suitable plants, bulbs, etc., for me (an amateur) to grow? I have a cool-house, with a temperature of 45 degs to 50 degs. (more with sun-heat), and frames. I am particularly anxious to grow *Primulas*, *Liliums*, *Freesias*, and *Violets*. These are what I find most difficult. I do not mean that I ask for cultural instructions about these things, as I watch for anything referring to what I grow in *GARDENING*, and when found make a note of it. —CHARTER.

[In such a structure as you name there should be no difficulty in succeeding with *Primulas*, *Liliums*, and *Freesias*, but *Violets* are scarcely likely to give satisfaction, as they need plenty of air, and in a dry atmosphere red-spider will attack the leaves. The *Primula* seed should be sown sown in the summer for winter and spring blooming. Beside the ordinary Chinese *Primula* there are others that can be recommended, particularly the little golden Himalayan *Primula floribunda*, the sulphur-tinted *Primula verticillata*, and the mauve or lavender-coloured *P. obconica*. This last is a most persistent flowerer, but when handled by some persons the leaves cause an irritation of the skin. *Freesia* bulbs are sent to this country usually in the month of August, and their potting should not be delayed after the middle of September. A convenient way of treating them is to put about eight bulbs in a 5-inch pot, give but little water till they start into growth, and plenty of light and air whenever possible during their growing period. *Liliums* should be potted now, or, at all events, with as little delay as possible. The most likely to give satisfaction are *Lilium longiflorum*, *L. speciosum* in variety, and *L. auratum*. After being potted, the cooler they are kept short of actual frost the better until the new roots have taken possession of the

soil. *Lilium longiflorum* is particularly liable to be attacked by aphides or green-fly, which collect to the crown or expanding leaves, and unless one is aware of this peculiarity, they often greatly injure the undeveloped buds before their presence is suspected. Vaporising with the XL vaporiser is the most effectual way of getting rid of these pests. Of *Lilium speciosum* there are several beautiful varieties, notably *album*, a white flower with brownish tinged buds; *Kretzeri*, green buds, flower white, with a greenish centre; *rosaceum*, pink; and *Melpomene*, carmine with a white edge to the petals. *OFL. auratum* there is a good deal of variation among the ordinary importations. It is rather an awkward season to suggest plants for your house, as there are so many beautiful bulbous and other spring-flowering plants that should have been potted some time ago—for instance, the more generally grown bulbs, such as *Hyacinths*, *Tulips*, *Narcissis* of different sorts, and such things, while some of the hardy shrubs are delightful when brought on under glass, the best being *Azalea mollis*, *Lilacs*, *Deutzia gracilis*, and *Lemoinei*. The different herbaceous *Spiraeas* which are sent to this country from Holland in large numbers for forcing are cheap, easily grown, and delightful when in flower, but they should have been potted at least a month ago. For the forthcoming summer you may grow the numerous quick-growing subjects that flower at that season, such as *Tuberous Begonias* (of which dormant tubers may be bought cheaply now), *Pelargoniums*, *Fuchsias*, *Heliotrope*, *Flowering Cannas*, and a host of other things. A few *Chrysanthemums*, the scarlet *Salvia splendens*, and the blue *Salvia azurea grandiflora* may be grown out-of-doors during the summer and taken under glass in the autumn, when their flowers will be much appreciated.]

Aspidistras with short leaf stalks.—I have many of these plants, some with as many as fifty leaves. But on most of the plants the leaves are very short (no stem to them). Will any reader of this paper let me know what I can do to make them grow taller? Do they require heavy or light soil? I wish to have a large one in a window looking south. But I fancy they do better without so much light. —R. J. HAWAII.

[The *Aspidistras* that one sees in shops have been grown in heat, which has a tendency to lengthen the leaf stalks, but even when grown altogether in the dwelling-house there is seldom cause to complain in this respect. Your plants must be thoroughly starved for them to behave in this way, and we should advise a general repotting with the advent of the month of April. The large masses will in all probability be the better if divided, as there is a tendency for the rhizomes to come to the edge, and the centre is thereby completely starved. In the case of those plants with as many as fifty leaves, they will be all the better if divided into two or three, and repotted in good, sweet soil. There is a great tendency to put the *Aspidistras* in two large pots, and if such is the case with yours you will probably find the roots in a far from healthy condition. In potting, see that the pots are clean and effectually drained with broken crocks or oyster-shells placed concavo side downwards, and take away as much of the old soil as possible. A suitable compost is from one-half to two-thirds loam, according to its consistence, and the remainder peat or good loam-mould, with enough silver-sand to be readily seen throughout the compost when thoroughly mixed. Pot moderately firm, and afterwards give enough water to keep the soil fairly moist, but avoid excess. Above all, never allow water to stand in the saucers, as this is a fruitful source of injury. *Aspidistras* do well in full light, but dislike exposure to the sun's rays.]

Oleanders.—Many do not succeed with *Oleanders*, but anyone with an ordinary greenhouse where a general stock of plants is kept can grow them. Some people turn them out-of-doors after they have done blooming, and in many instances this means that they suffer from want of moisture at the roots, and a failure to bloom them often ensues. It is a good plan to let them have a course of open-air treatment, as it ripens the wood, but they should be brought under glass again before the nights get cold in September. Just at present *Oleanders* will need a warm, moist heat; indeed, the want of a little extra warmth is a common source of buds dropping off. —TOWNSMAN.

CHRYSANTHEMUMS.

POMPON CHRYSANTHEMUMS.

For freedom of flowering the Pompons have a special value. In the past the Pompons have more often been referred to in disparaging terms, and yet there is no class which gives a better return for a period extending over many months. To be seen at their best the plants should be partially disbudded. Some sorts require to be more severely dealt with in this respect than others. Where the buds are developed in clusters, which are too dense and compact, these should be thinned out sufficiently to enable each bloom to develop without crowding. Many of the plants are sturdy and branching in their style of growth, and give excellent results. The following represent a few of the better Pompons—

WILLIAM WESTLAKE.—In this the flowers are larger than in many other sorts, and their colour is golden yellow, sometimes tinged red. The plant is a profuse bloomer, flowers developing from almost every joint. In flower mid-season. Height about 3½ feet.

Chrysanthemum Pompon Sour Melanie.

WILLIAM KENNEDY.—An excellent companion to the last named, being equal in every respect to that variety. The colour is a lovely purple-crimson. Height about 3 feet.

Mlle. ELISE DORDAN.—This, when finished, is represented by a perfect ball of neatly formed and compact petals. Colour, pale rose-pink. It is a neat and pleasing flower when partially disbudded. In bloom in late October and early November. Height about 3 feet.

OSIRIS.—A refined flower of good form. Colour soft rosy pink, edged gold. The plant is free-flowering, and also has a nice habit of growth. A good, reliable mid-season sort. Height about 3½ feet or rather less.

ROSINANTE.—Although a very old sort, this is still worth growing. It is very free-flowering, but to see the blush-rose blossoms at their best the plant should be somewhat freely disbudded, as it produces its buds in dense clusters. Height rather less than 3 feet. Mid-season variety.

EVNSFORD GEM.—This is a pretty variety which merits more recognition than it usually receives from growers. The colour may be described as purple-rose, and as such should be

welcome. It is of dwarf and sturdy growth. Height about 2 feet.

PRINCE OF ORANGE.—In this instance, orange-amber aptly describes the colour. Height about 4 feet. Mid-season.

BLACK DOUGLAS.—For its rich, dark crimson colour, this, which has somewhat fimbriated petals, should be in all collections. In this case good culture is required, and careful disbudding also is needed. A well-grown plant will attain a height of about 4 feet. A useful mid-season variety. Keep a sharp look-out for mildew in the growing season.

DOLLY.—This is not by any means a large Pompon flower, but its quality is excellent. The colour of the blooms is a lovely canary-yellow, and the petals are fimbriated. Height about 3½ feet. Mid-season-flowering variety.

PRESIDENT.—This is a very old variety, and often seen in flower in cottage-gardens, and public gardens also. It is free-flowering and robust, and comes into bloom in the early mid-season. Height 3 feet.

SEUR MELANIE.—Although this is a hybrid Pompon, it is still highly regarded in this section. It is a profuse bloomer, and the plant

fimbriated. When the plant is partially disbudded the result is very good. In flower about the second week in October till the same time in November. Height 2½ feet.

LITTLE PER.—Little is known of this variety. A bunch was exhibited at one of the N.C.S. December shows. It is a small, neat flower, and the colour may be described as blush. Height about 4 feet. Late mid-season.

PERRY.—This is another of the little miniature sorts, and to be seen at its best, should be cut from plants which have been only partially disbudded. Plants treated in this way develop beautiful sprays. Height rather more than 2 feet. Late mid-season. E. G.

NOTES AND REPLIES.

Chrysanthemums classified (H. P. M. S.).—The four varieties Mrs. C. Down, Mlle. Theresia Rankouke, Mme. Philippe Rivole, and Letrier represent a splendid quartette of late-flowering white Japanese Chrysanthemums. They should be classified as Japanese-reflexed, in which form they are usually seen when grown freely for decoration.

Chrysanthemums—when to insert outtings for a first "crown"-bud selection (An Old Reader, Walthamstow).—

Your object appears to be that of keeping the plants dwarf, and with this object in view, you desire your plants to make a natural "break" and develop first "crown" buds at a suitable period. We take it you want the blooms at their best in the early days of November next. The first series should be taken in hand at once, and the cuttings inserted without delay. The varieties in this category are represented by Ethel Fitzroy, W. H. Whitehouse, Mme. Nagelmackers, Charles Longley, Mrs. J. Bryant, and Mme. Paola Radaelli. Cuttings of those in the second series may be inserted in mid-February, the following answering well under this treatment: Miss Elsie Fulton, George Lawrence, W. R. Church, Calvat's '99, Mrs. Greenfield, Bessie Godroy, Henry Weeks, Mrs. J. Lewis, Lord Ludlow, George Carpenter, Mrs. E. G. Fox, Princess Monaco, Mr. T. Carrington, Mrs. E. Thirkell, Lord Alverston, Exmouth Crimson, Mrs. J. C. Neville, Duchess of Sutherland, Meredith, Princess B. de Brancova, and Mafeking Hero. A March propagation should suit the following, which we will regard as the third series: Mrs. George Milham, Mrs. Greenfield, Mrs. T. W. Pockett, Mrs. Harry Emmerton, Miss Alice Byron, The Princess, and Mme. Waldeck Rosseau. It is just possible that 1903 may be of such a character that our ideas may be completely upset. For this reason we would advise you to pinch the point out of any of your plants which may not have made a natural "break" by the end of May or the beginning of June at the latest. Secure first "crown" buds in each case.—E. G.

Amateurs' Chrysanthemum.—

"North Cotswold," who claims to be a considerable grower of Chrysanthemums, and yet an amateur in knowledge, asks if some contributor would give a list of fifty to a hundred Japanese varieties that will give blooms under an amateur's mode of growth, of a fair size, three or four to a plant. Now I consider this to be a task altogether unnecessary and, from an amateur reader's point of view, bewildering. What is the average reader of GARDENING ILLUSTRATED to do with a collection of even fifty varieties if he grows, as he should do, at least two, and of some sorts more than two, plants of each? The capacity of many a gentleman's garden would not find space for such a number of plants, and why, I would ask, should an amateur grower confine himself to Japanese varieties alone? Surely this section does not afford all the interest there is to be found or obtained from Chrysanthemum growing. From a decorative point of view, I hold the single Chrysanthemum, the Pompon, and Anemone Pompon to be infinitely superior to many of the Japanese varieties. Is there not something to admire in the refinement of a Clus. Curtis, or the purity of a Ma Perfection, both dwarf and easy doors?—S.

Request to readers of "Gardening."—Readers, both amateur and in the trade, will kindly remember that we are always very glad to see interesting specimens of plants or flowers to illustrate, if they will kindly send them to our office in as good a state as possible.

ROSES.

ROSES FOR SHELTERED GARDEN.

Will you please advise me what Roses to plant in a sheltered garden and in situation open to the sun for three-quarters of the day, as most fully satisfying the following conditions? I want six for planting against wooden palings 6 feet high, and three dozen for the border in front of the same. They must be on their own roots, at moderate prices, of very healthy, robust constitution, sure and abundant bloomers, and of decided beauty of colour and form. I do not care about having an equal number of each of the different colours. I want the most attractive and reliable. What are the most suitable situations for the Penzance Briet Roses, and what is the most effective way of planting them? Are they best in shady or sunny positions? As isolated bushes, or as climbers, or as trailers?—O. T. LAMBER.

[We fear, from the tone of your letter, that you would be most difficult to please. Of what you would consider beauty of colour and form, another individual might have quite a contrary opinion. Many people go into raptures at the exquisite shape and smallness of the Polyantha Roses, others are charmed at the *negligé* style of the newer Teas and Mouthlies. Then, again, the prize bloom is the ideal of many, they overlooking the fact that perhaps only one flower has been allowed to develop on the one plant, or, perhaps, in cutting this one bloom very little of the plant has been left. Therefore, when you ask for Roses, moderate in price, robust growers, abundant bloomers, and possessing beauty of colour and form, and then desire them upon their own roots, we imagine you are asking rather too much. It would be far better to make your own selection from specimens that you can see growing in a nursery or private garden, or, if you place yourself in the hands of a good, reliable nurseryman, you would have no cause to regret his selection. We name the following as being six good kinds for the palings: Monsieur Desir, Germaine Trochon, Billiard et Barré, Gloire Lyonnaise, Climbing Mrs. W. J. Grant, and Gloire de Margottin, and for the border you should select, mainly from the Hybrid Tea group, such varieties as Mme. Abel Chatsenay, Clara Watson, etc., but, for brilliant colour and fragrance, the Hybrid Perpetuals, of the type of A. K. Williams and Mrs. John Laing, should be well represented. As to the best method of disposing the Penzance Briers, there is no more effective style than as isolated bushes, or, say, in groups of three or five of a kind. You can see beds arranged after this manner at Kew Gardens, and they are charming in June when bespangled with their exquisite blossoms. Most certainly give them a sunny position, if practicable.]

NOTES AND REPLIES.

Liquid-manure for newly planted Roses.—I want your advice about the use of liquid-manure for newly-planted Roses. When could I use it for them after being planted? Also kindly let me know what I ought to use it for established Roses?—H. H.

[Do not apply any liquid-manure to the newly-planted Roses until they show bloom, and even then it should be very weak. A light sprinkling of some good fertiliser, applied at the end of May, and hoed in just before rain, will be beneficial. Established Roses may receive liquid-manure in May, and once a week onwards until the colour is seen in the flowers. Much benefit accrues to the plants if liquid-manure be applied now, or at least as soon as the frost is out of the ground. A store of fertilising food is thus made available for the future requirements of the plants.]

Pruning Rose W. A. Richardson.—I have in my garden, on a wall facing west, a William Allen Richardson Rose. It was planted there two years ago. Last year it bore only about twenty Roses, and these were poor, but it has thrown out some good shoots. The ground was carefully prepared before planting, and has received attention since. I want to try it another year, and think of cutting it back rather hard, leaving only the best of last year's shoots and just toping them. Will that be right?—H.

[By all means preserve the strong shoots almost in their entirety, but do not be too lavish in cutting away the other wood. Spread out this plant as much as possible, and then, where the growths appear crowded, cut a few clean out. The remaining laterals shorten more or less according to their strength. Instead of twenty blooms, you ought to obtain two hundred or more, if you manage this properly. After the first flowering you may advantageously cut away some growths, and this will considerably help you to obtain another fine crop next year.]

Pruning newly-planted Roses.—I planted some Roses in November, and want to know if they should be pruned in March of this year or not?—H. H.

[It is best to prune newly-planted Roses the first season, but not quite on the same lines as when they have become established. Cut close all soft, pithy wood to the base in the case of dwarfs and standards, and cut the hard wood back to half its present length. The Hybrid Perpetuals may be pruned middle of March, but the Teas and Hybrid Teas end of March and early in April.]

Pruning standard Roses.—I have Niphetos and Souvenir d'un Ami Roses growing in my greenhouse. The greenhouse, which has fire-heat enough to keep out frost, faces east, and these Roses are against the west wall, grown on rather high standards so that they may be above the glare. They were planted in November, 1903, and bore a few Roses last summer. They have made long but not strong shoots. Will it be right to cut them back a good deal, and if so now or in March? Should I prune now or in March some Roses bought last November, some being in the garden and some in pots in the greenhouse?—H.

[As regards the two standard Tea Roses planted out under glass, we think there is something wrong with their roots, or they would have made more progress. However, as they are alive you should cut them back rather hard, say to within five or six eyes of their base, and endeavour to help them at the root by preventing the water dripping upon them. Stir up the soil and sweeten by sprinkling on a little lime. The pot-Roses you may prune now, but the established and newly-planted leave until March.]

Larch trellis for Roses.—I am making a small Rose garden, and propose enclosing it on two sides with a 7 feet high Larch trellis—Larch poles split and bark left on for the sake of appearance, as it will be seen from windows of sitting-rooms. But I am told the bark will harbour insects, and therefore spoil the climbing Roses I had intended training on it. Would 6 inches apart from outside to outside make too much draught?—PLANT.

[It is quite unnecessary to remove the bark from the palings. We have never found any trouble from insect visitations owing to the bark being retained. It is a good plan to give the plants a syringing now and then with petroleum emulsion, which effectually disperses injurious insects, and also arrests mildew spores upon the plants. Six inches to 9 inches apart for the palings will be right. You need not fear trouble from draught. Of course, you will only plant the hardier climbing and rambling Roses thereon.]

GARDEN PESTS AND FRIENDS.

LEAF CURL.

"EAST DEVON" is quite right in attributing the cause of "Leaf curl" to a fungus (*Exoascus deformans*), but he has not given "G. H. N." much consolation in the way of explaining how to deal with the pest. There can be no doubt that cold, wet weather in the spring, particularly if it follows much milder weather, is very favourable to the growth of the fungus, as the leaves become saturated and softened, their transpiration is arrested, and the vigour of the tree is considerably lessened, conditions in which the fungus revels. When trees have been once attacked, and the weather is unfavourable to their growth, I very much question if such slight protection as that afforded by $\frac{1}{2}$ inch netting is sufficient to prevent unfavourable weather having a detrimental effect on the trees, and so rendering them more liable to suffer from the attacks of this fungus. The leaves may become infested from two sources. Sometimes the mycelium, or spawn, remains dormant in the shoots, and in the spring grows into the leaves, causing the cells infested to increase considerably in size. As the midribs and larger veins are not affected they remain of their normal size, consequently the softer parts of the leaves are obliged to assume the well-known crumpled and puckered condition which is known by the name of "the curl." At other times the leaves become infested from spores which have remained during the winter on the shoots near the young buds. It seems tolerably certain that the leaves become infested at a very early stage. The germ tube which issues from the spore creeps across the leaf until it finds one of the stoma, or pores, into which it enters, and at once finding itself in a more or less congenial position, according to the condition of the leaf, it increases rapidly by branching among the cells of the leaf, those near the surface in due course forming cells containing

spores. These burst through the skin of the leaf, which give it the peculiar whitish velvety appearance so characteristic of this disease. When quite ripe these cells burst, and the spores are liberated into the air, and are carried about by the wind. It is clear that except by cutting off the infested shoots nothing can be done to prevent the leaves being infested from the shoots, but it is supposed that this is very rarely the case, and for the very good reason that, by taking proper precautions to destroy the spores, the disease can, as a rule, be kept under control. The French orchards in America, which are frequently of a very large size, suffer very much from "leaf curl," but it is found there that the disease can be kept all by spraying the trees just before the buds begin to open with Bordeaux mixture, this killing the spores just as they are germinating, which is the time the fungicide has most effect on them. It is better to do it at this time than later, when the leaves are beginning to open, as then it is quite possible that they may have already been infested, and the spraying would then be of little or no use, and the tender foliage might be injured by the fungicide. I am not aware that this remedy has been tried in England, but I should strongly advise "G. H. N." or anyone whose trees suffer from this pest, to try it. Bordeaux mixture gives the trees a white coating, on account of the lime that is in it, but this is rather useful than otherwise, as it can easily be seen whether the spraying has been properly done, for it is very essential that every bud, and the shoots on which they are, should be reached by the fungicide.

G. S. S.

FRUIT.

PEARS FROM BUSH VERSUS WALL TREES.

I HAVE read with interest the notes by "W. S." on Pears in a recent issue. I know the garden well over which he presides. I am of opinion that more light would be diffused on the behaviour of Pears if correspondents would follow "W. S.," who should go further and name the kind of soil and stocks the Pears are growing on, when they differ so much in flavour in the same garden. Regarding Beurré Diel, I quite agree with "W. S.," having had it in just the same condition in a garden on a light soil in Hampshire. When in West Norfolk this Pear used to grow to a good size, and the skin was smooth from bush trees, and kept well till the close of the year. I have it growing on a north wall, but the fruit is only fit for stewing. I am of the same opinion as "W. S." that Duchesse d'Angoulême is overpraised. With me the fruit from walls is large, but very poor in flavour. On comparing it with fruit from the continent I find mine are much clearer in the skin. The continental fruits are evidently from bush trees, and their flavour is far better. Glou Moreceau, grown as a bush in Norfolk, is of the highest flavour, and the fruit is clean. During the past season one of the very best illustrations I have ever had of the advantage of trying many kinds, both as wall and bush trees, has been with Louise Bonne of Jersey. I have an old tree in the open, and some twelve years ago I had the soil removed around the roots and good soil added. This brought its own reward, as this tree has since then given me fruit of average size, but always rough in the skin. In point of flavour no kind in this garden can outdistance it, and I prefer the smallest of these before large, clean fruit from wall-trees, which are worthless. I remember it was the same with trees in a large garden in Buckinghamshire many years ago. Emile d'Heyst, with me as a bush, is a success. The same may be said of Alexander Lambre, while Hacon's Incomparable, growing by its side, is not worth the room it occupies. I have eaten fruit grown in this way in Norfolk fairly good. At a keeper's house on this estate there is a grand tree. The fruit grows to an enormous size, but is tasteless, although the tree is against a wall. The soil it is growing in is a strong loam, and it is on the Pear-stock. Josephine de Malines is worthless here from a wall—it was the same in North Hants, while fruit from bush-trees was fine. Beurré Base is splendid from a low wall; the same may be

said of Beurré Hardy. I never had Old Colmar so good as this year from a west wall, and although an old kind, it surpasses many more modern sorts. In some places Pitmaston is thought highly of, but with me it is only fit to stew, and this from a cordon tree on east wall on Quince-stock. Recently, at Hackwood Park, I found it was only second rate. Marie Louise in this garden, from a fine, large tree on west wall, is of poor flavour, while in a garden within sight, fruit from trees in the open is splendid, although rough looking. Winton Nolis is always of fine flavour. This year my fruit was fine both in colour and flavour. Another good kind is Ollivier de Serres; with me the trees will not grow on the Quince-stock; but this autumn, at Hackwood, I saw it doing well as a cordon. J. CROOK.

Fortis Abbey, Chard.

THE LARGER APPLES.

THESE form a considerable class of themselves, and by far the larger number of them belong to the cooking section. This is, in fact, as it should be, for nothing beyond a medium-sized fruit is desirable for the dessert. The larger Apples are most useful in their respec-

culture, and is less liable to disease than some kinds. Belonging to the same category is Golden Noble, and, considering the many years it has been in cultivation, a kind which should receive far more recognition than it has hitherto done. Cox's Pomona is another reliable kind for autumn use, and small examples of this when well coloured may be used for the dessert. Stirling Castle and Ecklinville Seedling are two free-bearing varieties. Stone's Apple is of handsome appearance, bearing early, and not making too much wood. Waltham Abbey Seedling is another first-class Apple; this was formerly confounded with Golden Noble, but it is quite distinct from that kind. As an early sort Alexander can be recommended as a good orchard variety. Winter or Red Hawthornden is larger than the old kind, and is also a good cropper. Alfriston is an excellent late kind. Two first-rate Apples are Bismarck and Sandringham. Peasgood's Nonsuch is a very fine-looking Apple, but it cannot be considered a good keeping variety.

NOTES AND REPLIES.

Pear-tree slug.—To prevent the ravages of slugs next summer on my Pear espaliers, a friend has

bone-meal, or sulphate of ammonia are any good, please say what quantity to use, and when to apply?—BURN LANE.
[It is possible that your fruit is small because an old and poor variety. The manning you have given the rows may do good. Perhaps you allow the canes to stand far too thickly. If in clumps, from five to six are enough to each clump, and these canes should be fully 4 feet in height and stout. In good soils the canes sometimes are left when pruned from 5 feet to 6 feet in height. If you would like to try another variety, then get young canes of Superlative, our finest Raspberry. As to chemical fertilisers, make up a mixture of bone-meal and kainit in equal parts, using this at once, and just forking it in at the rate of 6 lb. per rod of ground. You may sprinkle on the same area 3 lb. of sulphate of ammonia, crushed fine, during June, when growth has begun. Mulchings of stable-manure applied during the summer help the plants greatly in hot, dry weather.]

GARDEN WORK.

Conservatory.—The Abutilon family is a very useful one at this season in the conservatory. The only fault to find with them is their tendency to become leggy and naked below. This can be obviated to some extent by hard pruning in July or a little later. This produces a lot of small shoots which burst into blossom in the autumn and continue through the winter. One of the most useful varieties is Boule de Neige, a rather close habited kind; at least, closer than many of them, with a profusion of pure white flowers. Canary Bird is a good yellow kind. These two we find the most useful, but there are many others with red, salmon, and rose-coloured flowers, but they are not so fresh as the two named above. The golden-leaved form, Thompsoni, makes a very pretty plant in a pot, and is still more useful in the garden outside in summer. I have had it exposed to 6 degs. of frost without injury. Baskets when well filled are very attractive in the conservatory. Lachonalia (Cape Cowslips) planted thickly round wire baskets and well mossed are very pretty. The bulbs should be planted thickly just as they begin to grow. Many plants not usually associated with basket work may be used for filling baskets in winter and early spring. Bringing things up to the light is a great encouragement to growth, and in lofty houses such things as Primulas, Strotocarpus, Begonias, and various Ferns, Grasses, and Mosses, if tastefully used, will be very attractive. Skillful or tasteful arrangement has a good deal to do with the general effect. Many good plant growers are rather poor hands at setting their plants off to the best advantage, and this requires study. We do not so much want a heavy bank of bloom as lightness and grace. It is well to have plenty of blossoms, but we want to tone down with light, elegant foliage. Of course, Palms will do a good deal, and the Kentias are among the best for this purpose, or to take into the house. Besides Palms, the Bamboos and Japanese Grasses are very suitable for taking off the far too common stiffness of conservatory arrangement. There is abundance of cheap materials within the reach of the gardener if only moderate means are placed at his disposal. At the time of writing the weather is severe, and it will be better not to strain the apparatus for the sake of a degree or two of heat, but frost must be kept out.

Propagating-house.—This is one of the most useful houses in the garden now. There should be plenty of bottom-heat, either from hot-water pipes laid in rubble in the bottom of the bed, or else an iron tank should run along under each bed and be connected with the boilers. For speedy work I like the tank best, but any method which produces a brisk bottom-heat will suffice. The bed can be filled in with Cocoa-nut-fibre or sand. I have used both, but the heat rises best through sand, though the fibre retains it longer and is more genial. This is the time for putting in cuttings. During February and March anything and everything can be rooted from cuttings or raised from seeds in a low span-roofed structure fitted with bottom-heat beds. Many thousands of plants can be raised in a small, properly constructed house if there are

Apple Warner's King.

tive seasons either for baking whole or for the well-known dumplings. Apples of large size (or rather under) are not so much wasted in paring, relatively speaking, as the smaller ones; hence they are in that respect rather desirable than otherwise. When speaking of "larger" Apples we do not allude to those of abnormal size, brought about by other than ordinary methods of cultivation. These may in their way be all very well, and as specimens of high-class cultivation reflect credit upon the growers of such, but such fruits will not, when extra attention in labour is considered, proportionately recompense the cultivator. Those Apples which attain to a large size without more than ordinary attention are certainly most desirable, when the sorts are of a relatively good constitution, and at the same time reliable croppers. Of such is Warner's King, known also as D. T. Fish and Nelson's Glory, well illustrated in the accompanying figure. This Apple is in good condition for use from October to January. When generally shown in October at the autumn fruit shows it is of a fresh green colour, but a few weeks later on the fruit changes to a rich yellow shade. The tree is a vigorous grower and a good bearer, being suited to either pyramid or standard

advised caustic-soda (3 lb. to 6 gallons of water), applied now. Is this not a very dangerous article? Your approval or advice will be much valued.—W. ANDREWS.

[The proper recipe for making a solution of caustic soda and potash is, 1 lb. of the former, not to be touched by the hand, put into a tub containing a gallon of hot water to dissolve, adding to it 3 lb. of pearl-ash or crude potash, and after dissolving 1 lb. of soft-soap in a gallon of boiling water, add that and 10 gallons of water. It is then fit to use. Spray it gently over trees now, as it is very destructive to insects, Moss, or any form of life. As, however, the chrysalides of the Pear-slug winter in the soil, the solution may have no effect on them. Better remove to a depth of from 3 inches to 4 inches the soil over the roots, bury elsewhere, and replace with fresh. If the slug appears next summer, dust the trees freely in the evening with fresh slacked lime, giving a second dusting two or three evenings later. After a few days syringe hard with clean water to thoroughly cleanse the trees.]

Manuring Raspberries.—I have four rows of old Raspberry-canes which bear well, but the fruit is small. I have given two of the rows a mulching of stable-manure. Can I do anything else for them—give chemical fertilisers? The other two rows have had no manure at all. If kainit,

other worm-houses to receive the plants as they leave the propagating-bed. Grafting also is another means of propagation which can be successfully carried on in such a house. Roses may be grafted on roots of the common Brier, potted so as to cover the union, and plunged in bottom-heat there will be very few failures. Towards the end of February I have dug up young Brier roots from the hedges just as the buds were swelling, grafted them with Roses of various kinds, and have had good plants ready to plant out in June.

Late vinery.—All Grapes hanging on the Vines may now be cut and bottled in the usual way. A dry, dark room with a temperature of 45 degs. or so will do for a Grape-room. Place a bit or two of charcoal in the water to keep it pure, and look round the bunches once a week, but, as a rule, there is less waste from decay in the Grape-room than when Grapes are left hanging on the Vines. After the Grapes are all cut, prune the Vines, wash the rods with Gishurst compound, using a brush, and topdress the inside borders with good loam and bone-meal. If there has been any shanking, or if the Vines are losing tone and the roots are in a bad way, they may be partially or wholly lifted and new borders made, and the roots placed properly and laid therein. Vines soon recover from the effects of lifting if the work is done carefully and promptly. If the borders or any part thereof are outside, cover with leaves and litter when the borders are completed. It is not often necessary when making fresh borders to fill in all the space at once. A bed of suitable soil 8 feet wide will be sufficient for several years. The remainder can be added as required. A Vine border must be well drained, and in heavy soils should be kept above the natural level.

Frame ground.—Where much forcing is carried on with hotbeds there is some saving in running the ranges of beds close together, so that one range of beds joins the next, and so on. There will be space enough between for a man to move when attending to the crops, and the beet will be more regular, and there will be less need for linings or renewals. The frames for Potatoes can be grouped together. Carrots, Radishes, and Lettuces may form another group, and if Melons and Cucumbers are grown on beds, then groups will be deeper and wider, as these require more warmth. Among the cold frames such things as Violets, Coughflowers, Carnations, and half-hardy plants should have all the air possible when the weather is mild, but keep out rain. Plants plunged in ashes or Cocoa-nut-fibre require scarcely any water in such weather as we have had lately. Of course, the time is coming when moisture will be required, but the time is not yet. Sperra frames, if any (which is not likely), may be moved to a shed and repainted.

Window gardening.—There will be bulbs of several kinds in bloom now, including Freesias, which are among the easiest to have in the window. The bulbs must be potted early in August to flower now. Tobacco-powder is useful for plants attacked with green-fly. A little dusted over the insects will make short work of them, and it can be sponged off with the dead insects. There is still need for care in the use of the water-pot.

Outdoor garden.—The Roses should be sorted up during frosty weather. If the collar of the plant is preserved the upper part is not of much consequence. Standards may be sheltered with a spray or two of Bracken drawn through the head to break the force of the cold wind. I think Bracken is better than Yew branches, which are sometimes too heavy, and check the circulation. Sow Sweet Peas in pots for planting out by-end-by-end. Hollyhock seeds are best sown outside about May, as the plants are hardier; but seeds sown now in heat and grown on quietly will produce flowering plants by August. The single-flowered plants are very bright, and appear to be more robust than the doubles. If the seeds are carefully saved from distinct colours the seedlings come fairly true to colour. In pruning well Roses cut away some of the old wood to make room for the young strong shoots, which should be laid in nearly full length, only the soft points being removed. At the time of writing the frost is rather severe, and as soon

as the thaw comes all recently set out plants should be examined and the soil made firm round the stems. Frost has great lifting power, and this lifting lacerates the roots.

Fruit garden.—A wall may be quickly covered with cordon Pears on the Quince; either single or double-branched cordons may be planted. There is no disadvantage in having very large Pear-trees, especially if the wall space is limited. In a garden occupied with large trees, many of the Pears, especially the early autumn kinds, decay before they can be used; but with cordons a much larger variety may be grown, and the season extended. Very few of the late Pears are grown in small gardens. One of the best-flavoured late Pears—Bergamotte de Espere—does well on the Quince. I have had it very good on a west wall. Winter Nelis, Josephine de Meines, and Beurre Rance are good late kinds, but Beurre Rance should have a good aspect—south, if possible. Another way of growing Pears on wires is to stretch the wires about 15 inches or 18 inches from the ground, and train horizontally. I have seen a south border covered with wires in this way, and the trees planted along the centre of the border and trained each way at right angles. I was in a garden a short time ago where a long line of Pears, chiefly early kinds, had been trained vertically, and were bearing freely, especially such kinds as Bon Chretien and Beurre Giffard. All pruning and training should now be finished.

Vegetable garden.—Those who have not sown Tomatoes for planting under glass in warm-houses should lose no time. Start them in a temperature of 60 degs., and grow them in a light position near the glass. Grow them as sturdily as possible until well established in 5-inch pots, and then transfer to troughs, pots, boxes, or whatever method of culture is adopted. Always have a few young Cucumber plants coming on now. A good form of Telegraph is as useful as any for early work. Continue to gather manure reasonably fresh from the stable for Mushroom-beds. Open air beds must be well covered with dry litter. If water is required, have it warm, and add a little stimulant. Salt is a stimulant for Mushrooms, used in moderation. In bad weather wheel on manure, and prepare Pea-sticks. Sown in seed lists, and, when the seeds arrive, unpack, and keep ready for use in a cool, airy room. There is no advantage in sowing anything till the land is in a suitable condition. It is a good plan to have a besp of warm, dry soil under cover for the purpose of covering small seeds. This can be arranged in the clearing up of the rubbish-yard. This is a good season for making up hot-beds for all kinds of forcing. Do not forget to sow a few seeds of a good kind of Onion, also Leeks, Cauliflowers, and Brussels Sprouts in boxes in heat, to be afterwards hardened off and planted out. E. HOBDAV.

THE COMING WEEK'S WORK.

Extracts from a Garden Diary.

February 2nd.—Sowed a few seeds of a good strain of Brussels Sprouts in a box for early planting. A few seeds of Leeks and Cauliflowers have also been sown, and Ailsa Craig Onion is now coming up in boxes for planting outside early in April. This is a sure way of getting a good crop that will be safe from the maggot. Strawberries in bloom are looked over daily to fertilise the blossoms. Peaches in bloom are also receiving attention in a similar way.

February 3rd.—Advantage has been taken of frost to wheel on manure and smother-burn any rubbish and cuttings which have accumulated in the place assigned for them. Pea-sticks have been pruned. We find cuttings of the young shoots of Apples and other trees useful for stakes for various things. These are tied in bundles and dressed ready for use in bad weather. Seeds of Begonias and other things have been sown in heat, the pans covered with glass.

February 4th.—Fern spores of various kinds sown in autumn in worm-house are now being transplanted into shallow boxes, still keeping them in heat. Lillies, Bermuda and others, now making growth freely, require watching, for green-fly will make its appearance in the

centre of the plants. We find a pinch of Tobacco-powder dropped among the insects very efficacious, and the remedy is cheap. As fast as Azaleas come into bloom they are moved to the conservatory. The forcing-house is kept constantly filled up now.

February 5th.—After frost all recently planted things are looked over and soil made firm round the stems. Lawns and walks are rolled. Our Tea Roses were all earthed up sufficiently to protect the collar before frost set in, and will remain in this condition till the spring till the Roses are pruned. A south wall covered with Roses will have the pruning seen to as soon as the weather is favourable. All the long strong shoots will be trained in and some of the old wood cut out.

February 6th.—Early crops of most things required have been sown in small quantities, but we shall wait for other sowings till the land is in good workable condition. Crops of Early Potatoes, Carrots, Lettuces, and Radishes are coming on in warm frames. There are no better Lettuces than those grown on a bed of loaves in a frame, where there is just warmth enough for steady growth. Cuttings of bedding Lobelias are being rooted in boxes in heat. Dusted a little more lime and soot over Gooseberry and Currant-bushes to keep off birds.

February 7th.—The plot of ground intended for Onions has received a further dressing of short manure, and been forked over. In this condition it will remain till the Onions are planted. We always raise a fresh batch of Asparagus annually for forcing. The quickest method is to sow seeds in small pots singly, and plant out end of April or May when the weather is snitable. If we had room enough under glass, we should raise all our plants in this way, as so much time is gained thereby, and the plants never look back, but we cannot always do this.

BIRDS.

OUTDOOR AVIARY.

(REPLY TO "H. BROWN.")

CANARIES bred in an outdoor aviary are always stronger than those reared in breeding-cages, and the reason is evident, as both parents and offspring obtain better air and more exercise in the former. You must not, however, put your birds up till the weather is warm and settled, say about the middle of May. The best time for pairing your birds would be towards the end of April, and it is well to mate a two-year-old hen with a yearling cock, as the maturity of the hen will help her in any unfavourable changes in the weather after laying has commenced. The birds will pair better if each occupies a separate cage (but placed side by side) for a time before introducing them to the aviary. Two or three nest-boxes or wicker baskets should be placed in various positions; sometimes an evergreen, such as a Fir or Box, growing in a pot or tub, will attract the builder, and the nest will be constructed in its branches, edging much to the interest of the aviary. Some old mortar should be pounded and mixed with the grit-sand for the floor of the aviary, to assist in the elaboration of the shells of the eggs. Materials for building must also be supplied, either placed in a small net-bag or straw upon the floor for the birds to gather up. These may consist of dry Moss as a staple, mixed with a little soft meadow hay, cow-hair, and fine short wool, and just one or two small downy feathers to finish off with. The hen is usually the nest builder, the male acting the part of labourer, bringing the materials to his mate. A pair of Canaries will breed two or three times in the season, the number of eggs varying from four to six. The period of incubation is thirteen days, and when the chicks are hatched the male supplies them with food, and continues to do so till about the thirteenth day, when they begin to peck alone, the hen continuing to brood over her young as long as they remain unfledged. Just before the young are hatched the following supplies should be given, in addition to the ordinary food: A quarter of a hard-boiled egg, minced fine and rubbed through a sieve, and mixed with a little stale bread, steeped in water, and afterwards

well pressed, or stale bun crumbs. When the young birds are a day or two old a small quantity of Rape seed should be added, which has been boiled or scalded, and then washed to remove its acrimony; this should also be crushed. These supplies must be given in a perfectly fresh state, for if the food be sour the nestlings will become sick, and die. Although the young birds begin to peck at about three weeks old, the cock continues to feed them till they are fully able to cater for themselves; the hen often begins to nest again when the young have arrived at this age. Let your aviary face south, and be well sheltered; it need not stand so high off the ground as 4 feet, and the lower it is the more sheltered it is likely to be. Take care to always cover the front at night with some thick material, and, above all, beware of cats. The half inch mesh wire-netting will be suitable for covering the front of your aviary. S. S. G.

LAW AND CUSTOM.

Trespassing fowls.—I rent some pieces of ground for gardening purposes, and at the side of them is some Grass land, on which the occupier turns his poultry. My fence is of wire netting and of barbed wire, and is not in very good order, and my neighbour's fowls come into my garden and injure my crops. I have complained to my neighbour, and he says I have no claim against him. Is this so? Or must I fence against his poultry?—H. D.

[You are not required to fence against your neighbour's poultry; under no circumstances is an occupier of land bound to fence against poultry. Your neighbour is responsible to you for the damage done by his poultry, and you may recover the damages by action in the county court.—K. C. T.]

Cat and doves (R. C. C.).—Doves are not destroyed by the "watching" of a cat, so we presume your meaning is that the cat has actually killed them. If you catch the cat in the act of injuring the birds you will be entitled to take measures to save them, but you will not be justified in destroying the cat because she has offended, and if you do kill him its owner will be able to recover penalties. You can, however, sue the owner of the cat for damages, for a cat has no more right to trespass than other animals, and it is the owner's duty to keep it within bounds.

A partnership matter.—A friend and myself contracted to lay out a new garden for the sum of £40. I commence work at 8 o'clock each morning, but he does not come until 9.30, and sometimes later, and some days he does not come at all. I have told him that if he does not work as long as I do he cannot expect to receive half the contract money, and he says he shall not expect to, but I cannot prove this statement, as there were no witnesses. I am entering in a book the full time each of us works. Can he claim his £20 and keep it, or can I recover from him for the extra time I have worked?—A FIVE YEARS' READER.

[Your better plan will be to arrange to receive the whole of the price of the contract, and to afterwards pay him a share proportionate to the time he has worked. If for any reason you are unable to do this, and he receives half the contract money and refuses to hand over to you the further share to which you are entitled, you may recover the same by action in the county court. The book you are keeping will be of the greatest service if you have to bring an action, as it will be a record of the time worked by each.—K. C. T.]

Gardener and Chrysanthemums.—A singular story was told to Judge Mansel Jones at Rotherham County Court, on Dec. 20, when Mr. W. H. Micklethwait, one of the leading men in the Rotherham district, sued Thomas Squires, a gardener, for £14 damages, alleged to have been suffered through the defendant negligently or wrongfully removing the terminal buds from 280 Chrysanthemum plants. Squires had been in the plaintiff's employment as head gardener, but left in September last because he refused to do some work he described as a "labourer's job." It was alleged that before leaving he told an undergardener that he should "get even with the old man," and should destroy all his own "stuff" on the premises. When the now head gardener came he found the terminal buds had been removed from the Chrysanthemums. The defendant denied the charge, and suggested that the plaintiff had done it himself by "putting his own finger in the pie." The Judge, however, made an order for the full amount claimed.

CORRESPONDENCE.

Questions.—Queries and answers are inserted in GARDENING free of charge if correspondents follow these rules: All communications should be clearly and concisely written on one side of the paper only, and addressed to the Editor of GARDENING, 27, Farnival-street, Holborn, London, E.C. Letters on business should be sent to the PUBLISHER. The name and address of the sender are required in addition to any designation he may desire to be used in the paper. When more than one query is sent, each should be on a separate piece of paper, and not more than three queries should be sent at a time. Correspondents should bear in mind that, as GARDENING has to be sent to press some time in advance of date, queries cannot always be applied to in the issue immediately following the receipt of their communication. We do not reply to queries by post.

Naming fruit.—Readers who desire our help in naming fruit should bear in mind that several specimens in different stages of colour and size of the same kind greatly assist in its determination. We have received from several correspondents single specimens of fruits for naming, these in many cases being unripe and otherwise poor. The difference between varieties of fruits are, in many cases, so trifling that it is necessary that three specimens of each kind should be sent. We can undertake to name only four varieties at a time, and these only when the above directions are observed.

PLANTS AND FLOWERS.

Panax Victorice (Constant Reader).—This will succeed with ordinary stove treatment, and what may be called general potting soil—that is, about equal parts of loam and peat, or leaf-mould with a little sand.

Maranta Warscewiczii (Constant Reader).—This Maranta requires a compost of a rough nature, such as peat, and fibrous loam pulped to pieces with the hand and a liberal sprinkling of sand. It needs a shady position in the stove.

Pellionia pulchra (Constant Reader).—A pretty creeping plant, valuable for draping stages or furnishing the surface of large pots. It will grow in ordinary potting compost, and owing to its shallow-rooting nature, does not require a great depth of soil. It grows best in the shade.

Bougainvillea glabra (Constant Reader).—This is much harder than is generally supposed. It may be kept fairly dry in a warm greenhouse during the winter, started in the spring after the manner of a Fuchsia, at which time a little more heat is beneficial, and by the end of May removed again to the greenhouse. Some large specimens of this plunged in the turf at Hyde Park with the other bedding plants flower well towards the end of the summer.

Ostrowakya magnifica (Youngster).—This is nearly related to the Campanula or Belliflor family. The roots are thick, fleshy, very brittle, and of a deep descending nature, so that it is not at all adapted for pot culture, but should be planted out in some good, deep, well-worked soil, with which a little manure has been incorporated. It is perfectly hardy, and does not come from North America, but is a native of Turkestan, in Central Asia.

Fronde of Maiden-hair Fern (A. S. C.).—A good deal of the lasting properties of Maiden-hair Ferns is owing to the way in which the plants have been grown, as if they have been well exposed and are not cut till they have become mature the fronds naturally remain fresh much longer than if they are gathered while still soft. After being separated from the plant, they may be kept for some time if allowed to float in a receptacle filled with water.

Chrysanthemums on single stems in 6-inch or 7-inch pots (An Old Reader, Walthamstow).—In the reply given to you in our issue of December 20th, 1902, the different periods of propagation in which the varieties are divided up into series are given with the idea of retaining the first buds subsequently developing in the apex of the growth. Under normal conditions the buds should appear at a period best suited to the different sorts.

Standard Roses upon lawn (J. E. T. Garcon).—It is better that the turf be not placed quite up to the stems of the Roses. Air and rain can enter the soil more freely, and these are vital elements that must be provided if success is desired. We prefer to see small beds prepared around each stem, and carpeted with Tufted Pansies. Nothing can look more beautiful, and the shallow-rooting Pansies will not rob the Roses, but rather act as a cool mulch. Some fine manure and soil added now and then are beneficial alike to the Roses and the Pansies.

Sella maritima (Youngster).—This, also known as *Vigna maritima*, forms a large onion-like bulb, which grows usually towards the end of the summer or in autumn. The blossoms, which are borne in a dense spike, are greenish-white, tinged with purple. It requires the protection of a greenhouse, and should be potted in a mixture of two-thirds loam to one-third leaf-mould, and a sprinkling of sand. Give but little water till the leaves commence to push up, when more moisture will be required. During the winter keep dry for a time.

Lilium Hanson (Youngster).—This is perfectly hardy, but being one of the earliest of Lilies to start into growth, the young shoots and leaves are liable to be injured by late frosts and cutting winds if they are in the open, hence they should be planted where partially protected by shrubs, such as is usually done in the case of *Lilium auratum*. A Rhododendron bed is one of the best places for them. A bed of this Lily has for some years been very beautiful at Kew, the bulbs being planted among some evergreen shrubs about 3 feet high, which protect the young shoots during their earlier stages, but before flowering the lilies well overtop the shrubs, which in their turn form an admirable setting for the charming, yellow, gracefully-disposed blossoms.

Covering a steep bank (Rinda).—There are several ways in which such a slope may be advantageously clothed, and many plants are suitable for the purpose. For instance, cuttings or small plants of *Vinca* or *Periwinkle*, or, again, Ivy planted freely over the slope, would quickly form a covering, and the after attention

would be small. Or, in conjunction with projecting boulders or rocks inserted in the bank, you may plant *Juniperus Sabina*, *Cotoneaster microphylla*, and *Yucca recurva*, *Y. filamentosa*, and others, in such a way that a distinctly artistic effect would result. Then, again, such nearly evergreen Roses as *Wichuriana* may be planted with *Clematis Jackmanii* to clothe the bank, or with a few rocks or tree-roots jutting out here and there, you may plant any of the Mossy Saxifragas, London Pride, *Saponaria acymoides*, and the like, or you may cover the whole bank with a carpet of *Aubrieta*. Indeed, there are many ways of treating such a spot, and one of the simplest is the *Juniper*, *Cotoneaster*, etc., mentioned above. With a little modification a good rocky bank could have been formed, and planted for the most part with subjects of trailing habit, would look well.

Standard Roses dying at top (H. E. R.).—Roses on stems, known as standard and half-standards, are usually budded upon lateral branches of the wild Brier near the top, so that the stem would be entirely wild Brier. If your tree has started to grow from the base after the cutting back, which you gave it, the new growth is wild Brier, and the useless, unless you have cut it off next summer. You must be careful to take out this plant and replace with a healthy specimen. This should be done immediately the weather is favourable, then you may expect some blossom this summer. Bush Roses will grow much better than standards near large cities and towns. When standards are planted only the very freest-growing kind should be procured, for nothing is so unightly as a Brier with a puny, stunted head.

Garden in Cheshire (D. M. Peck).—From personal knowledge of the district to which you refer, we believe that a very general list of trees and shrubs may be grown with success. Certainly you may include *Magnolia conspicua*, *M. stellata*, and *Arbutus* and *Carya elliptica*, if in well-drained soil. If the soil is sandy loam many of the *Ilex* family will do quite well. As to the herbaceous plants, we would, without hesitation, plant almost anything we desired. We would not place the large array of herbaceous things at the mercy of a garden composed of heavy clay soil, for example. But where a sandy loam is at command, there should be little trouble, provided an intelligent method of dealing with the soil, as to trenching, manuring, and suchlike, in particular, be properly attended to. If the soil is freshly-dug pasture-land, you may be well advised to leave Carnations alone for a year or more, and Lilies also, on account of wire-worm, if these abound. In other respects we believe you are in a county where much gardening success awaits a consistent, intelligent method of planting with selection. You need not hesitate in putting to us any question on gardening concerning which you are in doubt.

Cactus Dahlias (H. E.).—You have hardly acted wisely in leaving these in the soil, and unless in a spot well sheltered or the plants well protected it is possible the entire lot may be injured or killed outright. This depends on the depth at which they were planted. Quite apart from this, however, there is ever the possibility of frost penetrating to the crown by means of the easy access through the old and hollow stem, and often this becoming full of water freezes and ruins the crown-buds. As you wish to increase them, it is the more unwise, as the plants are in the ground, as lifting is absolutely essential to the suggested increase of the plants. If you want but a few extra plants, in all probability free division of the root clumps will suffice, carefully shaking away all soil and cooling where the crown-buds are, then pulling the plants to pieces. In some instances a strong bud with tuber attached may be secured, and these form very satisfactory young plants. It is too early to see these buds yet, however, but in the case of very strong stools we have made six or even more young plants from each. If you want a quantity of plants your only way is by cuttings, securing these with a heel or base joint attached, and inserting singly in a pot of 2 1/2 inches diameter. The stools should be previously placed in the root greenhouse or frame, and when the young shoots are 3 inches long take them off and treat as usual.

Plants for beds (C. W.).—If the bed you refer to as on the lawn is that shown at the eastern corner of plan, we would recommend you to plant in an irregular shape in March some Tufted Pansies in colours all over the bed, starting, say, with a border of yellow and filling in the centre with a good blue or purple kind. In June, the centre portion could give place to *Tuberous Begonia*, either in mixed colours or sets of colours. These you may plant either thinly among the Pansies, or allow them to replace the Pansies altogether. If you do the first, the Pansies should be cut over as soon as the first flush of blossom is past, and presently they will flower again, this time forming a groundwork to the *Begonia*. Thus treated, with the Pansies as a sort of permanent margin, you will have a bed not only interesting and gay in summer, but effective till the autumn, and very desirable. An alternative plan would be to plant Ivy-leaved *Pelargonium* and peg them all over the bed. These are most profuse in their flowering. The narrow bed near the porch, seeing it is so much raised above the ordinary level, would appear to afford a good opening for some free-flowering alpine, such as the *Anthriscus*, alpine *Phloxes*, double white *Arabis* to form a groundwork, and small halibone plants as *Fritillaria*, Spanish *Iris*, *Aconites*, and *Astragalus*. Hybrid *Columbine* and *Poppies* would also grow quite well in such a place. If you think this too much, you could plant the carpet things first-named in conjunction with some of the Mossy Saxifragas, with *Daffodils* and *Crown Aconites* below to make a succession.

Growing Epiphyllums (W. W.).—After the flowering season is over the plants should have a period of rest, being kept drier at the roots and in a somewhat lower temperature. Having flowered in an interior house, the warm part of the soil should be very suitable. Potting, if not done in March or April, a very suitable compost for the purpose being two-thirds good yellow loam to one-third pounded brick rubble and soft bricks, with a liberal admixture of sand. A little well-decayed leaf-mould may with advantage be added if the loam is of a heavy nature. In potting, the soil should be pressed down firmly, and great care must be taken to keep the plant well secured to a stake or stakes, as if this is not done the weight of the branches is apt to cause them to

snip off. After potting, the plants must be kept warmer, with occasional syringings, in order to encourage a free growth, while the supply of water at the roots may be increased, but care should be taken not to overwater. The pots must be thoroughly well drained. As the plants increase in size they may remain for years without repotting, provided precautions are taken when potting them in the first place to keep the drainage open. Old-established plants will be benefited by a little feeding in the shape of weak liquid-manure during the growing season, and also just before the flowers develop. After the growth is completed the plants may be removed to a sunny greenhouse in order to ripen the wood and set the flower-buds, giving them at that period somewhat less water than when in full growth. The earliest may be taken into a little heat by the middle of September, and if a few at a time are so treated a succession may be kept up for a considerable period.

TREES AND SHRUBS.

Increasing the Holly (K. B.).—Seeing you can procure no berries, possibly can be increased from cuttings, which should be made of the ripened shoots of the current year's growth. These should be planted in a bed of sandy soil in a sheltered border, covered with hand-lights and shaded on bright days.

Fast-growing climbers for open palisade (W. Andrews).—Considering that the aspect is a northerly one, we only recommend such plants as will grow in this position. Of flowering creepers you could plant: *Wistaria sinensis*, *Honeysuckle*, *Jasminum nudiflorum*, *Yuccantha Lelandii*, *Clematis Jackmanii* and *C. montana*, *Everlasting Pea* (pink or white), *Gloire de Dijon*, *Chester Hybrid*, *Almae Vibert*, *Flora*, and *Félicité-Perpetue* *Roses*, and *Pyrus japonica* of sorts. This last is not fast-growing, but almost indispensable on account of its early blossoming and brilliant colour. *Virginian Creeper*, *Ivy*, and *Berberis stenophylla* are excellent. There are also many deciduous-flowering shrubs, such as *Syringas* (*Lilacs*), *Philadelphus* (*Mock Orange*), *flowering Currants*, *Weigelas*, etc., that are suitable for low fences or palisading.

FRUIT.

Apple-trees trained (J. Casswell).—There is no reason why the trees should not succeed, and if so treated that the fruit-wood will be of the best quality also. You do not say whether you wish for dessert or cooking fruits, however, so we give you some of each. It would be advisable to take the wire quite 12 feet high, and to make a start with quite young trees that could be trained in the way you mention without risk. Indeed, it may be possible, if you enquire of the nurseries near you, to obtain some espalier-trained trees, which are the most suitable for training in the way you wish. Good dessert kinds are: *Cox Orange*, *Beauty of Bath*, *Amazon*, *Mother*, *Claygate Pearmain*, *Golden Renette*, *Scarlet Nonpareil*. The following are good cooking sorts: *Emperor Alexander*, *Cox's Pomona*, *Ecklinville Seedling*, *Lord Derby*, *Lane's Prince Albert*, and *Warner's King*.

Pruning Nut-bushes (J. C.).—In pruning on either side of your walks the Cob Nut-bushes which seem to have become unduly high, we should have preferred to have cut out hard down as near the ground as possible some of the largest or oldest of the branches, then to have shortened back to 6 feet others evidently younger, spurting in on them weak growths, and leaving a few stronger shoots two-thirds their length. If there are numerous shoots or suckers springing from the roots, all weak ones of these kinds should be cut out, and just a few, say half a dozen of the best, encouraged to grow into branches, cutting them back one-third. Strong young shoots do not fruit until they have become older and branch out, or get up into light and air. Of those already pruned, we should advise cutting some of the older stems close down to thin them, leaving others and treating suckers as advised. No doubt the trees having been long planted, a heavy dressing of manure placed about each would do them great good.

Pears on Apple-stocks (W. G.).—The chief reason why Pears should not be budded or grafted on Apple-stocks is that the two fruits do not well assimilate, and when such cross-budding has been done the result always has been disappointing. We have heard of inter-crossing the Pear on to the Apple by fertilising flowers of the latter with pollen from the former, but the results again have been of doubtful character, and, if any, really then quite worthless. The Apple is *Pyrus Malus* and the Pear *Pyrus communis*. There is far closer identity between the Pear and the Quince (*Cydonia vulgaris*) than between Apple and Pear, as the Pear does well on Quince-stocks. Other than the Paradise-stock (*Pyrus pyracantha*), we know of no other stock than the common Crab or Apple seed raised stock on which Apples will thrive. Perhaps another valid reason for not thus using Pear-stocks for Apples is that they are not valued, as Apple-stocks can be had in great abundance and very cheap. There can be no better way to spoil any good Pear than by working it on to the Apple. Far better work it on to the Quince.

VEGETABLES.

Celery running to seed (A. Croft).—Very early sown and planted Celery invariably bolts, which yours has done. It seed be sown about May—always soon enough for all ordinary purposes—then it does not bolt. Still, much depends on how the plants are treated, as if allowed to become thick, starved and weak in the pots or pans, the plants will bolt away early.

Beetroot falling (G. J.).—As to your Beet being hard when cooked, that was perhaps due to variety or to poor soil. The latter cause is most probable. Generally we find all varieties are good now. For Beet the soil should have been well manured for a previous crop, then be in the winter dug quite deep, and again in April be forked over again, sowing the seed middle of May in rows 12 inches apart, thinning out to 6 inches apart. Keep the soil between the rows well hoed during the summer.

Planting Potato Onions (G. J.).—The best time for you to plant bulbs or offsets, as usually called, of Potato or underground Onions, will be the middle of February, as you are in a cold climate. Have the soil well manured and deeply dug, and when you lay the tubers some wood-ashes and soot before planting.

be in rows 10 inches apart, and the tubers in the rows be 12 inches apart. Press them well into the soil, so that the tops just show. Later, when good growth has resulted, draw away some of the loose soil with the hand round each cluster, as that will promote swelling.

Six good market Peas (M. J. C.).—In Lancashire, and where there is plenty of water, you can hardly do better than sow for a first early for market, say *William Hurst*. It grows about 20 inches in height unstacked, and could be sown thinly, in rows 2 feet apart. You would find to follow that *English Wonder*, sown in rows 20 inches apart, remarkably prolific, followed by *The Daisy*, in rows 30 inches apart, dwarf and a great cropper. Of 3-foot Peas sow *Senator*, *Triumph*, and the *Gladstone*, three splendid croppers and coming in succession. These latter, if not stacked, grow to about 30 inches in height. Be sure you get the true varieties.

Buried cattle bones (H. E. Johnson).—If the flesh of the animals buried in your garden ground, and which possibly died from some disease, has so far decayed that it has left the bones fairly clean, your best course would be to have all the bones thrown out to let them well dry, then get them broken up as small as possible with big hammers, and to then use the broken bone as manure. The finest, or dust, would soon become useful as food, the larger portions would decay in time and become food also. If the buried animals are in a pot, the best course would be to well smother them with fresh lime and well cover up with soil. Such an excess of flesh in the process of decay would do more harm than good to vegetable crops, unless very deeply buried. We do not mean it would make the crops unwholesome so much as coarse, rank, and, doubtless, very unprofitable. Deep trenching of the ground would do more good than this coarse feeding.

Good keeping Onions (Flora).—Generally it is found that the oval or globe-shaped Onions keep better than the flatter ones do. For that reason *James Keeping*, *Bedfordshire Champion*, *Sutton's Globe*, *Cranston's Excelior*, or others of similar form habitually keep well into the winter. But too much must not be assumed on that head, as we have seen plenty of flatter Onions keeping well quite late. So much really depends on how the hulbs have matured or ripened. They are often, on strong rich soils, helped to do that by having their necks gently pressed between finger and thumb during August, and the tops laid over on to one side. Still, in doing that care must be taken not to break the necks. If the season be damp, Onions grow late, do not ripen well, and therefore keep badly. For your springs be fairly early in county down you may sow seed thinly in shallow drills, 12 inches apart, drawn on soil that has been well manured and deeply dug previously, making the sowing at the end of March. Thin the plants to 4 inches apart later and keep clean from weeds.

SHORT REPLIES.

Choccol.—Put in the cuttings of the plants you mention during February and March. They must have a warm house or a hot-bed. —*D.*—We have never seen a bed consulte follow from pruning fruit-trees during hard frost. —*E. D.*—See article "Blister or Curl in Peaches," in our issue of January 17th, page 603. —*R. W.*—You will find it very useful for mixing with all sorts of potting soil, and top-dressing all kinds of soft-wooded pot plants. We have also used it largely when making Vine and Peach borders. —*Slag.*—We have handed your query to the Editor of *Farm and Home*, who will deal with it in an early issue. —*Amateur.*—Quite impossible for us to advise without seeing the place. Consult the practical man of whom you speak. It would be far better to make a fresh *Asparagus* bed in your new garden, lifting the crowns you have now and forcing them. —*P. S. Lingfield.*—Your best plan will be to obtain employment in some nursery where trees and shrubs are largely grown for sale. —*A. C. Stringer.*—Not a gardening query. Write to the Editor of *Farm and Home*, 17, Furlong-street, E.C. —*E. N.*—Certainly not. The manure you refer to will only cause fungus, and is of no value whatever. —*Shrub.*—Prune early in April. —*Young Novice.*—See reply to "A. M.," in our issue of January 17th, p. 606. See article on "Garden Edging," in our issue of January 3rd, p. 578. —*J. T. Horner.*—Apply to Messrs. Barr and Sons, 12, King-street, Covent Garden, W.C.

NAMES OF PLANTS AND FRUITS.

Names of plants.—1, *Carex japonica gracilis*; 2, Generally known in gardens as *Tradescantia discolor*, but its true botanical name is *Rhus discolor*. —*P. E. A. I. B.*—We can only suggest that the plant inquired about may be *Agathosmia*, perhaps *A. rugosa*, or near ally of the *Diosma*. —*J. Egan.*—*Chrysanthemum Mrs. Pilkins.* —*W. J. Townsend.*—Quite impossible to name from such material. —*Constant Reader.*—1, *Fanex Victoria*; 2, *Maranta Warcewiczii*; 3, *Pellonia pulchra*; 4, *Bougainvillea glabra*. See p. 627 for treatment.

Name of fruit.—*Mrs. Keeble.*—Apple *Gloire of the West*.

Catalogues received.—*Wm. Samson and Co.*, Kilmarnock, N.B.—*Spring Catalogue of Choice Seeds and Plants.*—*W. THE

Season of Spring follows the passing of Christmas, and ere long owners of gardens will be eagerly discussing the Seed Catalogues preparatory to making their selections of Seeds. If you have not yet sent for JOHN K. KING & SONS' Spring Catalogue for 1903, we recommend you to do so at once; it will be sent post free on receipt of a postcard to either Coggeshall or Reading. JOHN K. KING & SONS are Seedsmen by Royal Sealed Warrant to His Majesty the King, and their Seeds are well known in almost every part of the

EARTH

In this exhaustive and beautifully illustrated Catalogue, every variety of Vegetable, Flower, and Potato worth cultivating is fully described. The question for those who have not grown JOHN K. KING & SONS' Home-grown Seeds is,

SHALL

we continue to sow low priced and inferior Seeds which frequently fail to germinate; high-priced Seeds which are no better than others; or those grown on the great Essex Seed Farms of JOHN K. KING & SONS, which are supplied to their customers at about half the price usually charged? If you want your

YIELD

the best return, a constant supply of the choicest Vegetables and the most beautiful Flowers, with crops of the best disease resisting Potatoes, you cannot do better than send for JOHN K. KING & SONS' Catalogue. For 110 years JOHN K. KING & SONS' Seeds have enjoyed a high reputation; thousands of Testimonials testifying to their excellence have been received. As a sample of the following worth recording, MISS COOPER, Forecote St. Mary, writes: "The Seeds supplied by MESSRS. JOHN K. KING & SONS in their £2.25 Collection have given

HER

complete satisfaction." Whether for the large garden of the Mansion, the smaller gardens of the Rectory or Villa, the humble allotment of the Cottager or Artisan, good Seeds at a moderate price are indispensable. To the care and skill shown by MESSRS. JOHN K. KING & SONS in sending out the Highest Class Seeds at the lowest growers' prices it is to be attributed the continued

INCREASE

of their Business, which now extends to almost every part of the World.

PLANTS AND FLOWERS.

CHRYSANTHEMUMS.

CHRYSANTHEMUMS DETERIORATING.

THE haste which in the past has characterized all operations in the culture of exhibition Chrysanthemums is largely responsible for the weakened constitution of many of the varieties, which from time to time have taken a high position at the leading exhibitions. A new variety is in the first season grown to its fullest extent. As most exhibitors know full well, a promising novelty, no matter whether it be a seedling or a plant of a few years' standing, is grown for "all it is worth," in the language of the grower. From the very outset a strain is put upon the energies of the plant, and all through the growing season the same course of treatment is observed. This, being followed by a period of some six to eight weeks' treatment in a glasshouse, often overcrowded with plants, weakens the plant. For some months the plants are highly fed, so that when the time comes round for procuring stock, cuttings of a most undesirable kind are the only ones obtainable. But for the feverish haste to commence another season's work, plants grown in the manner just described could be treated in a way to restore, to some extent, at least, their lost constitution. Some of the leading growers plant out stock of the better sorts, but with the novelties they have no chance of doing so. When the few stock plants come into their possession, the Chrysanthemum specialists, to meet the demand for novelties made upon them, put in every cutting, and in the succeeding flowering season growers wonder why the new sorts fail to reach the standard seen during the previous season, and also so faithfully described in the gardening journals. The process of deterioration which begins so early in the life of the plants is continued in the two or three succeeding seasons, and unless the constitution of each one is exceptionally robust and vigorous, the variety, so to speak, goes to the wall. What else can we expect, after giving the plants so severe a system of culture? It is unreasonable to expect anything else than failure, and so long as the present system of early propagation is followed, so long will results be unsatisfactory.

It is not possible for every grower to plant out in his garden a batch of exhibition sorts, and many are not prepared to take that trouble. It cannot be denied, however, that it is a wise course to adopt, and it brings its own reward. If it is not possible to grow stock plants in the open border as suggested, other means, though not so good, may be taken to achieve somewhat similar results. Plants which have been subjected to high culture should, after flowering, be cut down and either have the ball of earth and roots redned, and be potted up into 6-inch or other smaller pots, using good soil for the purpose, or they should be plunged in soil in frames, or, better still, in soil of a fairly light character on the side benches of the glass-houses. The latter position is the better one,

and so long as the plants are not excited into quick growth by a high temperature, the resulting growths, which should develop in the early days of the year and just as the days begin to lengthen, should be all the grower desires. Cuttings from such plants may be put in with the reasonable prospect of producing satisfactory results. Instead of lanky and unsightly plants developing, those of dwarf to medium growth should be the result. These latter, too, are easier to handle, and also retain their foliage much better. I have just seen a batch of plants treated in the manner described, and these are now freely developing growths of a sturdy kind. A January and February propagation is quite early enough for all purposes. C. H. N.

CHRYSANTHEMUM BLOOMS IN VASES.

WHAT is wanted at exhibitions in connection with vase classes for cut Chrysanthemums is more of that free-and-easy style of setting up the flowers seen in our own homes. When it is required that so many blooms only be shown in a vase to be judged chiefly as exhibition flowers and without any other foliage, then it is inevitable that the class or classes will become as monotonous and objectionable as are the board classes. I could but notice in our own show here in Kingston last November, that by far the prettiest vases of blooms were those of amateurs and cottagers, who had not only a free hand as to flowers and arrangements, but also brought their own vases, all being more or less diverse. These were far more pleasing than were the large show bloom classes. It seems to be very evident, judging by what has been written, that the public or amateur taste, so far as Chrysanthemum shows is concerned, is rebelling against the big or fat flowers in vases, and is asking for something much more pleasing, decorative, and artistic. The fat flower classes are the fond children of those whose highest aim in flower culture is to win good prizes. These exhibitors must be given to understand that such ideas in relation to flowers are becoming repulsive. There is now, in relation to Carnations, a great rebellion against dressing the flowers and showing them with paper collars. The same thing is cropping up in connection with the showing of Roses—still so terribly formal in their boxes. So also with Dahlias, even the beautiful Cactus forms being shown in rigid wire frames in the most unnatural way, so that people are getting tired of seeing them so displayed, and are calling for more natural methods of showing them. But of all flowers none seem naturally better suited for vase display than Chrysanthemums do, as they have long, stiff stems and can be set up in almost any lengths, thus admitting, especially in conjunction with draping foliage, most pleasing and graceful arrangements. Show committees cannot too readily lend their attention to what the public ask, and cater less for the old stereotyped lumpy blooms which for so long have been the exhibitors' favourites. One unpleasant feature of the big bloom competitions is that the trade men in their business to knock out varieties that have been favourites after a couple of

years or so of showing, because old varieties have become plentiful and cheap. That is done by forcing on growers new varieties that can hardly be said now to show advance or diversity on the old ones, but which can be charged high prices for, and if some will not foolishly purchase them others will. Chrysanthemum showing has been a fine trade boom, but it has seen its best days, happily. A correspondent, "Essex," sneers at market blooms. He is welcome to do so, but his sneer will only help stay the growth of public taste for more beauty and less bigness in Chrysanthemums. A DEAN.

NOTES AND REPLIES.

Plants to carry 20 or 30 blooms.—I wish to grow a few Chrysanthemums with from 20 to 30 blooms each on a separate stem, and would be glad to know the names of six of the most suitable kinds (different colours) and how to manage them from the time the cuttings are struck?—YORKSHIRE.

[Had you inserted cuttings of the varieties you intend to grow a month earlier you would have enhanced your prospects of success. Still, provided you commence operations without delay, and use some bottom-heat to hasten the rooting, you may make up for some of the lost time. The most suitable kinds for your purpose, in different colours, are: Lizzie Adecock, rich yellow; Crimson Source d'Or, orange-crimson; White Quintus, pure white; Pink Selborne, lilac pink; Bronze Soleil d'Octobre, bronzy-fawn; and William Soward, a deep rich crimson. Each of the above-mentioned sorts is of easy culture, and given proper treatment should make a fine display. When the plants are about 6 inches high take out the point of the growth. Keep the plants rather dry at the roots for a few days to assist in the development of new shoots in the axils of the leaves. From the several new shoots select two or three of the stronger, growing these on, and rub out the weaker ones. Pot on the young plants into larger pots from time to time, using those 9 inches in diameter in which to flower them. Never pot on a plant until it has filled its pot with roots, and never pinch a plant at the same time that it is being repotted. At least a week should elapse between the two operations. After the first stopping, already described in detail, you should pinch out the point of each succeeding 6 inches to 8 inches of growth, giving the final pinching about the third week in June. This must necessarily develop plants of a bushy character. We would advise you to partially dishud your plants, and if you prefer to have flowers of medium size on stiff, erect stems, retain only one bud on each shoot. Throughout the summer and early autumn give the plants a good open sunny position, standing them on boards, slates, tiles, or anything of this kind to prevent the ingress of worms. Insert strong stakes or Bamboo canes for the support of the branching growths, lightly looping these to the stakes with raffia. Do not feed the plants until the flowering pots are well filled with roots. House the plants during the last week in September. Greenfly, if present, may be eradicated by dusting with tobacco powder. (NEWSVAT.)

OUTDOOR PLANTS.

MICHAUX'S BELLFLOWER (MICHAUXIA).

The *Michauxias* may for all practical purposes be regarded as biennials. In certain instances,

Michauxia Tchihatcheffii. From a photograph by Mr. D. S. Fish, Edinburgh.

however, it may be that the plants do not attain to flowering size the first year, and, therefore, do not bloom. The plants invariably perish with the ripening of the seeds. These remarks are made to prevent disappointment arising from regarding any of the species as truly perennial. To be successful in the cultivation of *Michauxias*, a system of quick growth is essential from the very first. The object of this is to secure the fullest possible development in the first season. The plants are easily raised from seeds, which may be sown in pots or pans of sandy soil during the early part of the year. If sown in slight warmth and under glass, which may be helpful, care should be taken to prick off any seedlings as these attain sufficient size. By this method and the subsequent growing on singly in pots, plants of good size may be secured for planting out in May or early in June. Plants not large enough for planting out by the end of July would perhaps be better grown on in pots and given frame protection for the winter. To obviate this sow the seeds prior to March, or in frames or pits in autumn. The *Michauxias* are essentially adapted for grouping among thinly-planted shrubs, so that their towering spires of white flowers may rise above the shrubs and be seen to advantage. Soil of a sandy nature always warm and well drained is best. Soils not of this description may be

rendered more porous by the addition of grit, old mortar, or charcoal, or sand. A deep soil, so that the roots may quickly spread, is the most likely to give good results. Leaf-soil may be used, but no manure, unless it be of a kind that can be rubbed through a fine sieve. Treated in this way there is every hope of growing these striking and exceptional plants with success.

M. CAMPANTULOIDES.—Fully developed, the spire of flowers of this kind will reach as much as 7 feet or 8 feet high, hence the need for a sheltered position and early attention in staking, etc. The flowers are white, slightly tinged on the outside with purple or lilac, the division of the corolla much reflexed. At the time of the opening of the flowers the plant and the upper parts of the inflorescence in particular are of a viscid or clammy nature. The flowers are more or less drooping, and arranged at intervals on the stem. This species has been long known to cultivation, having been brought from the Levant in 1787.

M. TCHIHATCHEFFII.—This handsome and striking species is so much of a novelty that only a few have as yet grown it. The branching character and the complete flowering portion of the inflorescence are so well shown in the accompanying illustration that further description is not necessary. In addition to the fine flowering, however, the plant is attractive by reason of the greyish leaves, which are covered with a soft short white down. This tomentose character is a feature throughout the plant. The leaves are far more abundant than in the first-named species. The flowers are white. This noble species was found in the Sicilian Taurus by M. Siehe, at an elevation of some 5,000 feet, the plants growing chiefly among rocks, and usually in

TUFTED PANSIES (VIOLAS).

WINTER PREPARATION OF BEDS AND BORDERS

To grow these plants satisfactorily year after year, not only must the flowering quarters be changed from time to time, but deep culture is absolutely necessary. Some persons appear to think the Tufted Pansies are surface-rooting, or at most shallow-rooting plants, and, because of this, ordinary culture will answer very well. The Tufted Pansies revel in soil which has been well tilled and deeply dug. Deep culture invariably brings its own reward in healthy and robust plants, which flower profusely and keep the garden gay for many months. At this season the grower should be busy preparing his beds and borders for the next display. It is an immense advantage to get the garden dug, and deeply dug too, in the winter months. In most situations, where the garden is not absolutely in the bottom of a valley, the soil should work comfortably, unless the weather be exceptionally wet and the soil also of heavy texture. I always make it a rule to dig two spits deep, incorporating at the same time thoroughly good manure. In years gone by, when blooms of exceptional quality were desired, the soil has been even more deeply tilled, and the advantage in so doing has amply justified the extra work and trouble taken. The surface soil should be left in a rough condition. In the case of poor and impoverished soil this treatment vastly improves it. Garden soil in which the Tufted Pansies have been grown several years in succession may to a large degree be much improved by these means, and in gardens of limited dimensions, where it is not possible to change the soil for these plants, surely it is worth while taking pains in its preparation for next season's display. When left in a rough con-

Michaux's Bellflower (*Michauxia campanuloides*).

the mountainous portions. Attaining to 7 feet high and more, it is not difficult to picture the fine effect of such a plant, with its closely-arranged, almost columnar spike of flowers. The latter covering about one half of the entire length of the plant.

dition on the surface, as previously advocated, the frost breaks up the heavy soil and pulverises it. In addition, insect pests, which so often infest the soil, are eradicated, and by its exposure to the air the soil also is rendered more productive. Garden soil of a light and

sandy nature is greatly improved by the addition of old and well-rotted cow manure. In most suburban and country gardens this material is not by any means difficult to obtain, many farmers and cowkeepers in the immediate neighbourhood of one's garden usually being pleased to provide a supply for a comparatively small consideration. Soil heavy in texture should be treated to a liberal dressing of well-rotted horse manure. Experience has proved that this is better than incorporating fresh stable litter. When the planting time again comes round, from the middle to the end of March, all that needs to be done is to lightly fork over the surface soil of the beds and borders, and rake them over preparatory to planting out.

D. B. CRANE.

Highgate, N.

LILIUM LONGIFLORUM INSULARE.

Without showing any marked divergence from the normal form, varietal names have been

many features in which it differed from any other longiflorum were claimed for it, yet, after a season or two in this country, all these points vanished. Whatever a further acquaintance may lead to, there is no question that these imported bulbs represent one of the best forms of *Lilium longiflorum*, particularly for a cool-house, or for growing out-of-doors. Of the bulbs which flower in this country, we draw our supplies from Japan, Holland, Bermuda, and South Africa, as well as from the Pacific Islands.

L. longiflorum (or *Harrisi*) var. *insulare* is very free blooming. Three bulbs sent up seven stems about 2½ feet high, which bore 29 beautiful flowers.—W. E. G.

HERBACEOUS PLANTS ON GRASS.

MANY species belonging to this class of hardy plants would create a much finer effect if grown singly or in bold clumps on the Grass, where

prefers liberal treatment, and for it give a good return. A firm, holding soil is more suitable for the general body of these plants than a light sandy one, although some few may need a little attention to give the best results. The stations where all are to be planted should be deeply trenched; if the soil is poor, some partly decomposed farmyard-manure and old potting-soil ought to be added, and will well repay the extra labour incurred in giving a more luxuriant growth, which means an enhanced appearance. All the plants here mentioned are the better for copious soakings of water at the roots if the weather be hot, and dry during the summer months. Some of the species have not sufficient foliage near their base to hide the soil in which they are growing. This might be improved by covering the surface soil with some of the many low-growing hardy plants, such as *Sedum glaucum* and *S. Lydium*, *Herharia glabra*, *Antennaria tomentosa*, or *Veronica repens*, all of which are of

Lilium longiflorum insulare in Mr. W. E. Gumbleton's garden at Pelgrove. From a photograph by G. A. Champion.

plentifully showered upon the varieties, or supposed varieties, of *Lilium longiflorum*, one of the latest being that at the head of this note. As flowered from imported bulbs, it is certainly full of promise, for the growth is sturdy and robust, two or three stems being often pushed up from one bulb, while the flowers, of which several are borne on a stem, are unusually expanded, and of a thick wax-like substance. Taking an isolated flower, one is reminded of a particularly good form of the Japanese variety *Wilsoni*. The name of *insulare* is but a geographical form, whose points of difference will disappear under cultivation, remains to be seen, for when first *Lilium longiflorum* *Harrisi* was sent here from Bermuda

they could obtain more freedom for both foliage and flower alike than they very often receive now, huddled together in a much too narrow border, where the true character of the plant is altogether obscured. Besides, a feature in the garden might be very easily added, which would give increased interest. If such an idea were more generally carried out and the Grass kept short, the plants would give even a finer effect than they do now where employed in the wild garden, where it is necessary to allow the Grass to run to keep up the true character of that part of the garden. Many of our finest herbaceous plants are remarkable as much for their foliage as for the flower itself; long Grass would altogether spoil the effect. In that case, therefore, Grass which is kept short is preferable under the above conditions. How the plants shall be arranged is more of a matter for personal taste than for minute instructions in this article. This section of hardy plants

quick growth and of suitable colours to form an agreeable contrast with the plants above.

TELERIA SPECIOSISSIMA, or, as some prefer to call it, *Buphthalmum*, is a capital subject for growing on Grass. The habit of the plant is vigorous, having large drooping leaves, which cannot be seen when surrounded by other things in the herbaceous border. Stout flower-spikes 4 feet long are freely produced, having blooms much resembling Japanese Anemone *Chrysanthemums* in their formation; the colour is orange-yellow.

POLYGONUM CUSCUTATUM is just the plant for this purpose: the growth has an outward tendency, deep green; the drooping, feathery panicle-like flowers are creamy-white, freely produced. If larger growth is required, *P. sachalinense* may be planted, which will quickly run up 10 feet high. The former variety does not grow more than 5 feet high.

BUCCONIA CIRCATA, commonly called the

Plume Poppy, if planted in a bold clump would give a noble effect, growing, as it does, from 6 feet to 8 feet. The glaucous colour of the underside of the leaves gives it more variety. The flower-spikes from strong roots are fully 3 feet long, creamy-white in colour.

FUCHSIAS of the Riccartoni, microphylla macrostemma, and fulgens types are excellent subjects for growing on the Grass. Well-shaped bushes upwards of 8 feet in diameter can be quickly obtained. In this way this class of Fuchsia is seen to the greatest advantage. The bulk of the varieties flowers profusely the whole of the summer and they are among the easiest plants to increase; the wonder is they are not more cultivated than at present. Rarely are they seen beyond cottage gardens if one excepts botanical collections of hardy plants.

ACANTHUS MOLLIS AND **A. SPINOSISSIMUS**, commonly called Bear's-breech, are very suitable for growing on Grass. The foliage is broad, deeply lacinated; they have white and purple flowers and grow about a yard high.

ACTÆA SPICATA (Baneberry) would give extended variety if planted in conjunction with other things named. The foliage is bold, and the numerous flower-spikes which strong plants freely throw up have a good effect, so uncommon are they in form.

TRITOMA OLAUCESCENS AND **T. UVARIA** are second to none for this method of garden ornamentation; the bright orange and red of the flower-heads make an agreeable contrast with the deep green of the foliage and the Grass. **T. glaucescens** opens its flowers first, and they are more frasily produced than those of the older **Uvaria**, of which it is a form, and a good one, too, for extending the flowering season of these showy Flame-flowers.

ERYNGIUMS would be useful to extend the flowering season, and their bright-blue flowers are at all times appreciated. The small-flowered amethystinum is free; therefore, worth a place. The deeper-coloured and stronger-growing **Oliverianum** is perhaps the best of the genus.

INULA MACROPHYLLA AND **INULA OLANDULOSA** would be quite at home on the Grass, their deep orange-coloured flowers contrasting so well with the Grass.

MONTBRETIA POTTSI and the newer crococciflora are well suited to this form of culture; the semi-drooping habit of the narrow leaves fits them well for growing on Grass; the orange and red flowers, too, are freely produced and pleasing.

SOLOMON'S SEAL (*Polygonatum multiflorum majus*) is another hardy plant well suited to this form of culture; in good soil the stems increase in strength annually, and produce a greater profusion of the peculiarly coloured greenish flowers, which are very sweet-scented; the berries, which are afterwards produced in quantity, render this plant still more interesting.

SPIRÆA ARUNCUS (the large Goat's-beard) has handsome foliage and showy, graceful drooping plumes of almost white flowers—certainly a desirable plant for growing on Grass.

This list does not by any means exhaust the stock of suitable plants for this form of hardy gardening, but has been given to afford a general idea of a plan which cannot fail to prove interesting.

NOTES AND REPLIES.

Flowers from Ireland.—Enclosed collection of flowers all picked from the open this day (January 22). I would be pleased if you could name the "Rose," which I think could be justly called "the Last Rose of Summer." I bought it last spring, a dwarf Perpetual, as a Baroness Rothschild. It bloomed from July till now, these buds being the last. I cut 85 blooms, which I consider exceptional for a first year, and the little tree is still growing. Probably the climate here has something to do with the extended season, judging by the Mignonette, etc.—**T. M. MACGIBRE, Kingston, Bray.**

[With the above note were sent some Rose buds (certainly not Baroness Rothschild), Mignonette, dark and yellow Wallflower, and *Lavatera arborea variegata*.]

Perennial Lobelias.—A correspondent in a recent issue makes some suggestions trying to account for the behaviour of the perennial Lobelias in winter. In some places people find that they cannot, or think they cannot, leave Lobelias in the open ground throughout the

winter. Your correspondent mentions having these plants unprotected throughout the severe winter of 1893, and no harm resulted, while on the other hand we hear of people losing their plants in a comparatively open winter. In Norfolk I have left spare plants in the ground, and they have, as a rule, taken no harm, but I could never depend upon them shooting up again in the spring. I believe that it is not intense and continuous cold that hurts the plants, so much as a changeable season—a season in which one never gets one temperature for any length of time. Most of the damage is done by the late spring frosts after the plant has started into growth.—**G. E. P.**

ROSES.

ROSES UNDER GLASS.

WHERE Roses are grown in cold houses or in those only moderately heated, it is quite time to see about pruning the plants. Should they be just received from the nurseryman, they are, as a rule, thoroughly ripened and the pots full of roots. It is always advisable with such plants to remove about an inch of the surface-soil, replacing this with a little new compost consisting of good loam and well-rotted manure in about equal proportions. Remove all sticks and prune the growths back to good plump eyes. Something depends upon one's object as to how the pruning should be done. If we desire to form them into specimens with a view to exhibiting say next year, rather hard pruning must be resorted to, the ripe stout growths cut back to four or five eyes, and, if possible, with the top-eye on each shoot facing outward. A good start is thus made towards forming a shapely plant. Where quantity instead of quality of blossom is desired, then a much more moderate pruning will suffice. In all cases keep the centre of the plant open. This can be assisted by careful tying out. As soon as the pruning is completed tie a piece of string beneath the rim of the pot, then bring down the growths slightly by means of a piece of twisted raffia secured to the shoot and string beneath the rim. When thus prepared, put the plants upon inverted pots and bring them as near the light as practicable. No water will be needed at the root until new shoots have pushed about half an inch, then it is advisable to give a good soaking, repeating the watering in two consecutive mornings, but prior to this the plants should be syringed with cold water every fine morning immediately after pruning. Abundance of air must be afforded from the commencement. If this is adhered to mildew troubles will be minimised. When cutting east winds prevail, the side air should be shut off from the side whence they come. I prefer to keep a crack of air at the top on nearly every night, the exceptions being during frosty weather. Even then, when artificial heat can be given, a buoyant atmosphere is preferable to a stuffy one. What Roses do not like is a check of any kind. A uniform system of treatment is the one that leads to success.

Where one can devote one house or more entirely to Roses, success is almost assured, but the Hybrid Perpetuals do not go well with the Tea-scented, the latter requiring a higher temperature. Such of the Hybrid Teas as approach the Teas in habit can be grown with the latter, and these—such as Captain Christy—having more of the Hybrid Perpetual nature, should be grown with the Hybrid Perpetuals. Crimson Rambler grown in pots pays for a sprinkling of some good artificial manure at the time of pruning, taking care to well water it in. Another application is given when the buds commence to swell. This is a Rose in which the grower's skill is made very manifest. Splendid trusses, well-coloured, are quite possible from young plants if the above practice be adopted. Old specimens should be relieved of a lot of their woody-out wood. The one and two-year-old shoots give the best quality of blossom. These Roses, and others of the same ilk, such as Dorothy Perkins, are invaluable for decoration. If their long shoots are twined around three Bamboo-canes they make beautiful objects for recesses and similar positions, and last a long time in flower. Being much addicted to red-spider the springs

must be freely plied, directing the water well beneath, not above, the foliage. Yellowish looking leaves, if examined with a magnifying-glass, will be found to be covered with red-spider beneath.

In preparing a selection of pot-Roses do not omit the pretty little Polyanthas, *Perle d'Or*, *Eugenie Lamesch*, *Gloire des Polyanthas*, *Schneewitchen*, etc. They group beautifully with the *Crimson Rambler*. Small plants even in 8-inch pots come in most useful for this purpose, or as table plants. So also do the *Monthly Roses*, *Queen Mab*, *Laurette Messimy*, *Aurore*, *Cora*, *Cramoisie-Superieur*, *Fabvier*, *Little Pet*, etc. In large gardens *Pillar Roses* and standards in pots give the gardener much valuable material for the conservatory, and the fragrant *Penzance Briers* and other single kinds have a beauty all their own. **ROSA.**

NOTES AND REPLIES.

Hybrid Sweet Briers.—Hybrid Sweet Briers are capital subjects where one desires to form a screen or block in a garden. Not a few have discarded the common *Privet* and *Quick*, and more than one dividing fence in a garden I have seen was composed of these charming flowering Briers. No one can form any idea as to the beauty and freedom with which they bloom during May and June, and they may still be planted when the weather is suitable. It should be borne in mind, however, that these Briers do not need pruning to cause blossoms. On the other hand, the less the knife is used in this respect, the better.—**LEAMURAZ.**

Rose Her Majesty failing.—Can the fact be explained—that *Her Majesty* will do nothing here, either out-of-doors or in? I write from the West of England, and a nobleman's gardener tells me it is the same with him. The flowers just slightly show their centres and then rot off. Someone has told me that this Rose requires more heat than it would get in, say, such a cold summer as this last, but it has been next to *La Rosiere* in a season with sun hot enough to burn the petals of that variety. After—when we get them—three or four fine days in succession, we still gather beautiful examples of *H.P.'s*—for instance, *Ulrich Brunner*, *Captain Hayward*, and *Queen Cordel*. Teas will not expand, and for some reason several have done very badly last season. One, *L'Idée*, planted in 1901, has just kept alive, and *Corotese de Nadal* the same. I have potted the former. It had roots enough for a small Gooseberry bush. Altogether the past season has been distressing. Some Apple-trees appear dying. Bush fruits were not up to the mark in flavour, while weeds have quite beaten me.—**C. R. S.**

Roses for bank.—I have just been obliged to course of levelling to make a bank about 8 feet high. It looks to the south, but is exposed to south-west gales. It is a dry piece of ground. Would *Wichuriana* Roses be suitable? If so, should they be planted on top of bank, and how far apart? And should bank be turfed or not, and if not should it not be carpeted with evergreen, like *Saxifragas*, etc? If *Wichuriana* is not suitable, suggestions for planting other things would be welcomed, as I do not desire a Grass bank, as I am sure here it would never be green in summer, and makes labour in cutting it.—**PLANT.**

[*Rosa Wichuriana* and its hybrids are admirably adapted to the purpose you require them. We should advise you to plant at the base and train the growth upward. They will push out shoots near the roots, but those not required can be cut away. If the bank is fairly wide at the top, say, 2 feet, you could plant some plants there also about 5 feet apart, but we fear the dry position would be against their success. However, the plants are very cheap, and you would still have those at the base to ultimately cover the bank. The *Wichuriana* Roses make enormous growth in a season. We have shoots now upon *Jersey Beauty* over 10 feet long. All this wood was produced last season. A four-year-old plant covers an area of quite 100 square feet. Just now its glistening green foliage is beautiful, and is quite uninjured by recent frosts. As a start we should recommend planting those at the base of the bank 4 feet apart. You need not turf the bank, as if the Roses do well they will soon hide the bare ground.]

Request to readers of "Gardening."—Readers, both amateur and in the trade, will kindly remember that we are always very glad to see interesting specimens of plants or flowers to illustrate, if they will kindly send them to our office in as good a state as possible.

ORCHIDS.

MILTONIAS.

This genus consists of a large variety of plants, some of the species having scores of named varieties, though the number of actually distinct species is small. They are epiphytal plants, natives of South America, some of them being of close tufted habit, others having the pseudo-bulbs occurring at varying distances on short creeping rhizomes. Their culture varies a little in the different species, the candida, Clowesi, cuneata, and Regnelli varieties being, perhaps, the easiest to grow and flower well. These like a good sound compost, consisting of peat fibre cleared of every bit of sand and earth with Sphagnum in about equal proportions. Mix with this plenty of very finely broken crocks and charcoal, but not large lumps. The roots are small, and though liking a compost that air can enter freely, they are not so satisfactory if it is too loose. In potting let the compost be pressed very firmly, first filling the lower two-thirds at least with drainage material. For a little while after

kind to that mentioned for the Clowesi section. Where roots are fairly plentiful they may easily be fixed in pots or baskets, but badly-rooted ones are more easily accommodated on rafts, as a wire may be used for fixing them. Very little difference is needed in the summer and winter temperature for these Orchids, and they thrive well in the cooler part of the Cattleya-house. Plenty of water is needed while growth is active, and while at rest the compost must be kept just moist. Nearly all the kinds mentioned above have a pale yellow tint in the foliage, but this is quite natural to most of them and not a sign of ill-health. *M. cuneata* is greener—in fact, it should be of quite a deep green if perfectly healthy—but the others, and especially *spectabilis*, will always be poor in colour. *M. vexillaria*, *M. Roezli*, and *M. Phalenopsis* used to be included in *Odontoglossum*, but they now usually called *Miltonia*. The first-named is one of the grandest of Orchids, and so well known that no description is needed, and its culture may be said to present no great difficulty. It does best in medium-sized pots, in a compost not heavy enough to

each, these being large individually. The sepals and petals are yellowish, barred with reddish-brown, the lip pure white in the typical form, but having many variations. It is a native of Brazil, and was introduced in 1830.

M. Clowesi is not unlike the last named in habit and general appearance, and thrives under similar cultural conditions. The blooms are large, the scape many-flowered, the outer segments chocolate-brown with spots of yellow. The lip is almost heart-shaped, pure white in the front, the base a deep vinous purple. This is not so variable as some other kinds, yet there are many which have received varietal names. This also comes from Brazil, and was introduced in 1843.

M. cuneata is one of the best known kinds from the same country. The spikes bear about half a dozen flowers, these being prettily undulated on the sepals and petals, brown and green in colour; the lip white, spotted with rosy-purple. Its proper flowering season is in early spring, but it sometimes blooms again in autumn.

M. Moreliana is a beautiful species, usually classed as a variety of *M. spectabilis*, but there are so many sub-varieties that it seems quite entitled to be kept apart. The spikes bear single flowers in late autumn, these being large, deep purple on the sepals and petals, the lip lighter, often with radiating lines of a deeper hue. The varieties differ considerably in colour and size, the flowers of the best forms being each over 4 inches across.

M. Phalenopsis is a dwarf tufted plant, with pale green narrow leaves and pseudo-bulbs, the scapes rising from these and carrying a few flowers on each. These are white, with lines of purple in the centre of the lip. It occurs naturally at considerable elevations in New Grenada, whence it was introduced in 1850.

M. Roezli and *M. Vexillaria* are very nearly related kinds, both lovely in bloom and well worth every care to bring them to perfection. The former bears pure white flowers with a purple centre, and there are several named varieties.

M. Spectabilis, the type of the genus, was introduced in 1837 from Brazil, and is still one of the most useful Orchids grown. The single-flowered scapes rise about 8 inches high, the outer segments are white at first, afterwards becoming a pale yellow, the lip varying considerably in the different varieties, but usually being of some tint of purple.

Callicarpa purpurea—Judging by the remarks overheard at the November show of the National Chrysanthemum Society, where a well-berried specimen of this *Callicarpa* figured in one of the miscellaneous groups, it was a decided puzzle to many gardeners, yet it ought not to be, as such an ornamental shrub as this well merits more attention than it gets now-a-days. It is an old plant in gardens, having been introduced from India in 1822, and at one time was more grown than it is now. Pruned back hard in early spring the plant will, in the temperature of an intermediate-house or the cool part of the stove, break freely into growth, when the production of long-flowering shoots should be encouraged, as it is these that bear the autumnal display. The little whitish blossoms which are borne in clusters in the axils of nearly every leaf on these long, wand-like shoots, are in themselves insignificant, but they are succeeded by berries

Miltonia spectabilis Moreliana. From a photograph by Mr. Geo. E. Low, 2, Glenageary Hill, Kingstown, Dublin.

repotting it is not advisable to keep the compost very moist, though it needs frequent watering, owing to its running dry so quickly, but after this the roots must be kept very moist until the young pseudo-bulbs are quite finished. Even in winter they must be kept moist, requiring even than as much moisture as some Orchids do in summer. The best position for this class of *Miltonia* is a light one, but not where direct sunlight can reach the plants. The plants vary considerably in their time of flowering and resting, *M. Clowesi* blooming, for instance, sometimes in July and August, at others in December, and this will, of course, be kept in mind in all cultural operations.

Quite a distinct section is that comprised by *M. spectabilis*, *M. Moreliana*, and *M. anceps*. The pseudo-bulbs occur on stout creeping rhizomes and the roots are small, though very persistent in most cases. All in this class abhor anything like closeness in the compost, and also dislike much material about the roots. On trellised rafts or in shallow baskets they are usually satisfactory, and they may with care be grown in well-drained pots. About an inch of material is ample for small and medium-size plants, and this may consist of a similar

get close or to hold moisture and dry, yet fairly substantial. It should be repotted some time after growth commences, just as the roots are forming, and until this occurs they may be kept well on the dry side after blooming. When the young pseudo-bulbs are finishing and the bloom-spikes forming, the plants require plenty of moisture. An intermediate or Cattleya-house temperature suits it best, the growth and flower being much finer than if grown in a cool-house. Much the same treatment is needed by the other two kinds named in this class, but both of these do with more heat all the year round than *M. vexillaria*. The following comprise the leading kinds:—

M. Anceps is a dwarf and pretty kind, producing its blossoms singly on the scapes, and these are olive-green and brown of varying shades, with purple markings on the outer segments, the lip being white, spotted and barred with red. It comes from Brazil, whence it was introduced in 1831, and is by no means a common species.

M. Canoga is a useful, free-flowering, and easily-grown kind, and in its best forms one of the handsomest of autumn-flowering Orchids. It bears long spikes of blossoms, eight or nine by

which, when ripe, are of a bright violet colour. Another desirable feature is that berries which ripen in the autumn often remain fresh till the spring. Cuttings root readily—indeed, it is, taken altogether, a plant of easy culture.—X.

INDOOR PLANTS.

GRASSES IN POTS.

WHERE pot plants are required for decoration throughout the year the object aimed at is, of course, to supply as great a variety as possible. Several of our hardy Grasses readily lend themselves to pot culture, and by their means some light and pleasing groups can be formed in the greenhouse during the summer months, added to which they are extremely useful. Being at their best during the summer just when the greenhouse is usually supplied with a great wealth of flowering plants, these Grasses serve to tone down any strong colour which often prevails at that season of the year. Where needed only for cutting from, the seed may be sown in the open ground during the showery weather of April, when it will soon germinate and grow away freely. In pots, however, these Grasses are most appreciated before the outdoor ones are sufficiently advanced to be effective. To ensure this, a good plan is to sow the seed from the middle of February to a corresponding period in March, according to the weather and other considerations, for should it be very cold and dull nothing is gained by sowing it then, as given bright, open weather it quickly germinates.

There are two methods of treating these Grasses in pots, one being to prick them off when large enough to handle, and the other to sow them in pots in which they are to flower. This latter plan is the better, the principal consideration being not to sow the seed too thickly, as when the plants are overcrowded much of their beauty is lost. Pots of any size may be used, but the most useful are those 5 inches or 6 inches in diameter, as they are handier than larger ones. A small amount of drainage, yet sufficient to be effectual, with a good holding soil suits the various Grasses. To accomplish this, one good crock in the bottom of the pot is enough, when the soil may be put in and pressed down fairly firmly, leaving in the case of those with minute seeds a space of about half an inch from the rim of the pot, and rather more for the larger ones. Loam lightened with a little decayed manure and sand will form a very suitable compost. The seed having been thinly sown and lightly covered, the pots may be placed in a cold frame and kept pretty close till germination takes place, which, with bright weather, will not be long. Plenty of air should be given to encourage as sturdily a growth as possible, but even then in most cases some slight support will be necessary for the plants as they grow up. The practice so popular with market growers for the support of many plants is to insert four sticks at equal distances apart around the edge of the pot, and pass a piece of stout thread or matting from one to the other, giving it a twist around each stick to hold all in position. If this be done directly the plants are tall enough, the foliage which is produced afterwards will hide both sticks and ties, while at the same time the plants will be prevented from falling about. As the pots get full of roots the plants must not be allowed to suffer from want of water, otherwise the foliage will soon get sickly.

Some of the best Grasses for this treatment are the dwarf-growing *Agrostis pulchella*, the taller, yet even more delicate, *A. nebulosa*, and both forms of the Quaker or Totter Grass (*Briza maxima* and *B. minor*). *Hordeum jubatum*, the long Barley-like awns of which are of a purplish tint when young, but when mature soon fall to pieces, will also be found useful. *Lagurus ovatus*, with its white downy heads supported on slender stalks, also does well in pots, and is very distinct from anything else, while to these may be added the loose-growing *Bromus briziformis*. Seeds of the above are readily obtained, and most seedsmen now keep a well assorted collection of ornamental Grasses, as many are available for sowing in the open ground that will succeed in pot culture.

NOTES AND REPLIES.

Hyacinths in pots.—I have some Hyacinths in pots, and I am keeping them in a dry, dark cupboard with silver-sand on top. They have pushed up above the soil. Please say how to treat them for the future!—WEEKLY READER.

[If your Hyacinths have well filled the pots with roots you may stand them in the window or on a greenhouse shelf. It would have been far better if you had plunged them in the open in Cocoa-fibre or coal ashes. They are probably very dry, and we fear the spikes will be very poor.]

Hyacinth culture.—Kindly give exact directions for culture of Hyacinths in pots. The gardener insists on keeping them buried under mountains of ashes till many inches high. I feel sure this is wrong.—H. C. WILSON.

[Your gardener is quite right. Hyacinths, after being potted, should be plunged in the open air in ashes, where they should remain until the pots have become well filled with roots, when they may be brought into the greenhouse as near the glass as possible. Unless well-rooted, failure is sure to follow, many people laying the blame on the seedsmen for such failure, while at the same time the fault lies in the treatment meted out to the bulbs after they have been potted.]

Unheated glasshouses v. severe frost.—In the southern counties, where the frost is generally less severe than in the midland and northern districts, of late years an enormous lot of unheated glasshouses has been erected, principally for the growth of *Toratoes* in summer, and in our ordinary winters forming a convenient shelter for *Chrysanthemums*, salads, and various other crops that need keeping dry rather than warm. We lately had some exceptionally severe frosts for the early part of December, with the result that the majority of the *Chrysanthemums* for the Christmas trade were spoilt. This will mean very serious loss to the class of small market gardeners who live on the outskirts of large towns. Unheated glasshouses are, in my opinion, of much more use in early spring for forwarding various crops than they are for really winter protection, for as soon as the sun's rays begin to make themselves felt, and the days to lengthen, you may plant or sow any crop with safety a month in advance of the open-air sowing. In the very shortest days the cold greenhouse is a delusion, for because the plants are under glass one is apt to think they are safe, but when the thermometer runs down rapidly in the open air one will find that its fellow in the unheated house is following pretty closely, and that a sheet of glass is but a poor protection in severe weather.—JAMES GROOM, *Gosport*.

Freesia refracta.—In growing this a mistake is often made in keeping the plants in too high a temperature, as the foliage becomes weak and Grass-like, and falls over unless supported—a remark which also applies to the flower stems. A good light position in a structure where a temperature of 45 degs. to 50 degs. is maintained will suit this *Freesia*, as under such conditions the growth will be sturdy and the foliage of good colour. Considerable numbers of bulbs are imported into this country, but it is not always the largest that give the best results, for the biggest I ever saw were grown in Bermuda, yet I could not succeed in flowering them in a satisfactory manner. Those from the South of France and the Channel Islands, as a rule, give good results. About eight bulbs in a 5-inch pot form effective specimens. As the pots get full of roots a little soot-water occasionally is of service. Carefully attended to in the matter of water after the flowering season, and given a good light position in the greenhouse, the bulbs will develop and ripen properly, so that they will flower again the following year. The golden-coloured *Freesia aurea* is, I see, for the first time offered for sale, but I have as yet seen no announcement of the delicate pink *Freesia Armstrongi*, which, though little known, has flowered in this country. Beautiful as they are, these last two are wanting in perfume.—T.

Winter flowers for personal wear.

—It follows, as a matter of course, that those desirous of having a supply of flowers for personal wear during the winter can only ensure a continuance by having access to a house properly heated. There are rare exceptions, like the *Hellebore*, which bears winter blossoms to be had out-of-doors in the

depth of winter under a handlight, but for a supply of blooms we must look to other things under glass. One of the most useful for making up into sprays, etc., is the *Bouvardia*. It is with me now in full beauty. There are, for instance, the double white *Alfred Neuner*, *President Garfield*, double pink, and singles like *President Cleveland*, red, and *Candidissima*, white. *Chrysanthemums* will naturally suggest themselves to the minds of many, and the later the varieties the more acceptable as the winter goes on—size of bloom is not aimed at, so much as neat blossoms for the coat. What neater for wear could one have than the sprays of *Chrysanthemum Snow-drop*, now so rarely seen? *Azaleas*, Roman *Hyacinths*, double *Primulas*, *Cyclamens*, *Heliotropes*, *Abutilons*, are all suited to the purpose mentioned, whilst *Roses* in pots on the roof will provide roany choice blooms as the spring wears on. The growing of the subjects mentioned to have flowers all winter entails more in the matter of preparation and providing for a succession than keeping the house up to a high temperature—indeed, it is rather the house where a uniform heat is found where winter blossoms are mostly found.—LEARNER.

Browallia elata for winter.—In the autumn and winter blue flowers are not too abundant, more especially for cutting. This plant, although only an annual, is a most useful blue-flowered plant to cut from. It is of the easiest culture and may be had in bloom the greater portion of the year, provided seed is sown at different times. It is very useful during the autumn and winter months. Last year I had it in bloom through the winter and till March in a warm greenhouse. When the plants are nicely grown they are useful for placing in vases. Any plant that can be grown quickly and that has such useful qualities should be better known. The best way is to sow a little seed in July. When strong enough, prick out the seedlings, putting three round a 3-inch pot. Place in a cold frame for a few days, after which remove them to a warm spot in the open air. When the pots are full of roots, pot into 4-inch, 6-inch, or 8-inch pots, as the case may be. They are then placed in a cold frame, and when the weather becomes too cold and damp removed to a greenhouse shelf, using every effort to keep them dwarf. Should a few be needed early, they are removed into a house with a temperature of 50 degs. by night. The plants should be pinched according to the size they are needed and time they are wanted in bloom. This *Browallia* is not particular as to soil. Loam, old *Mushroom* manure, and sand, two parts of loam to one of manure, adding sand enough to keep it open, grow it well.—H.

Bouvardias planted out.—“A. W.” note on *Bouvardia longiflora* in a recent issue of this paper is instructive. It shows that at least one variety can be made good use of in the open-air. Planting out can also be practised by those who do not care to be troubled with the labour involved by pot culture. Lifted carefully in early autumn and put into pots just large enough to contain the roots, they will bloom all through the late autumn and early winter months. When *Bouvardias* are grown in pots all through the season they must have skilful treatment and a lot of attention—more than most amateurs are able to give them; but planting out in suitable soil at the right time is sure to give good results. The best way is to set them out in frames, as in this way several weeks are gained, and one can make sure that the young growths are not checked by spring frosts. The soil should be nice and free, with a little well-rotted manure or some concentrated manure in it. If the plants have been wintered in a cool greenhouse they may be planted in April, keeping on the lights with free ventilation until the end of June, when they may be removed altogether, if so desired. In this way they will make a strong growth, and in a general way a much larger quantity of flowers will be produced than by pot culture. When lifted in the first week in September they should be put into pots just large enough to contain the roots, placing in a frame and keeping rather close until new roots are made. Watering carefully.—J. C. E.

GARDEN PESTS AND FRIENDS.

Plague of woodlice.—My Melon and Cucumber-houses are very much troubled with woodlice. The woodlice only appeared last year for the first time. They eat the roots of the Melon and Cucumber plants, and also get in at the bottom of the pots containing the Ferns and flowers and eat away at the roots. They have also eaten the flowers of Hyacinths just as the bloom was on the point of bursting out. The other week I had everything shifted, and burnt a good deal of sulphur in the two houses, which when closed up are almost hermetically sealed. This does not appear to have destroyed the pests. What is the (1) best way of getting rid of the woodlice, and (2) when they are got rid of what is the best way of keeping clear of them?—WINTERKENT.

[Woodlice are most injurious pests in Melon-houses. They very probably congregate in considerable numbers between the soil and the sides of the wall. If this be the case numbers may be killed by pouring boiling water over them, or many may be caught by laying pieces of slate, or tile, on the soil, as they are fond of hiding under such things during the day. These traps should be examined every morning and replaced as near as possible in the same position. Woodlice are such hard scaly things that no insecticide used as a wash will kill them. They may be poisoned

have no doubt done their share, though it has been a much smaller one. The best thing that you can do is to give the ground a heavy dressing of gas-lime, and fallow it as long as possible. I should not grow Cabbages, Turnips, or any plants of that description on the ground that an infested crop has been grown on, for at least two years.—G. S. S.]

Apple-tree unhealthy.—Herewith the head of a young standard Apple-tree (Gascolgne's Scarlet). I have cut off the side shoots, so as to facilitate sending by post. You will notice that the bark is coming away in flakes, as it were, and the tree is dead. I only planted it two years ago in my small Grass orchard. Can you inform me what disease it is suffering from, and how I can prevent the spreading of same any further, as three other trees are attacked in the same way? I discovered several small white maggots under the bark of the tree.—BLAIR WILLIAMS.

[The head of the Apple-tree that you sent was attacked by the grubs of the fruit-tree Bark beetle (*Scolytus rugulosus*), which was no doubt the cause of the death of the tree. This insect is very closely related to the *Scolytus* that at times does so much injury to Elm-trees, but it is considerably smaller, measuring not more than one-tenth of an inch in length, or about a third of the length of the Elm *Scolytus*.

FRUIT.

THE USE OF LIQUID-MANURES IN WINTER.

With overflowing tanks and heavy rainfall, many do not give a passing thought to the use of liquid-manures which may be charging the waste pipe instead of supplying fertility to the garden soil. During the winter months, where there are store tanks to receive drainings from the cow-yard, stable, or piggeries, these soon become filled with a liquid which may, or may not, have a value. At this season, while there is ample moisture in the soil, there is not so much need for diluting this clear water as in summer, because the actual presence of rain-water in the soil at once affords the necessary toning down of its strength, and consequently removes risk of danger to tree or plant roots. There are few gardens wherein is found all the necessary fertility of soil that is required for trees and crops. Fruit-tree roots penetrate to soil beyond the influence of surface tillage, and the older the tree, the greater is the area of

Miltonia vexillaria. (See page 633.)

by mixing phosphorus paste with Barley-meal. The mixture should be placed in small heaps on bits of tile or glass. It is said that pieces of Potato boiled in water with a little arsenic will poison them.]

Maggots in garden soil.—The soil of my garden has become infested with small white maggots, which have attacked the roots of all my Cabbages, Cauliflowers, Savoys, and Carrots, destroying the whole crop. Last spring the ground was fairly heavily manured with stable-manure. The subsoil is gravel and sand. The garden is in a somewhat exposed position and the climate mild and damp. I send you two Cauliflower roots showing the damage done by the maggots, and I should esteem it a great favour if you could advise me what treatment to pursue to cleanse the soil?—R. A. V. M.

[I was unable to find any maggots in the soil about the Cauliflower-roots that you sent. I examined them very carefully, and am not at all surprised that they did not do well, for they were badly clubbed, besides being attacked by the grubs of the "Turnip gall-weevil" (*Ceutorhynchus sulcicola*), which had formed galls on them, slugs, and one of the Poduridae or "springtails." This species, however, does not jump away when disturbed. These are little narrow insects about 1/4 of an inch in length. Perhaps it is these insects which you allude to as maggots? As far as I can judge it is the "club-root fungus" that has been the main cause of the mischief. The other pests

This insect does not bore much into the wood, but makes its galleries just between the wood and the bark. I was unable to find any of the beetles, but there were a good many grubs still in their tunnels. The most effective way of destroying this insect is by burning the infested trees, if they are in very bad condition, or cutting off and burning the affected parts. As the beetles are winged they can easily pass from one tree to another in an orchard, so that drastic measures should be at once taken to prevent the pest from spreading, and it is seldom that a tree, when once attacked, ever really recovers. In the majority of cases wood-boring insects only attack trees that are not in very vigorous growth, as a large amount of sap in the tissues of the tree kills them. It has been found useful to pare off the outer bark so as to induce a flow of sap to the bark, and at the same time to manure the tree so as to bring it into a healthy condition. In order to prevent any of the trees in your orchard, which are now free from this pest, from being attacked you should use every means in your power to keep them in perfect health, and in May and June, when the beetles are about, spray the stems and branches that are likely to be attacked with a green or paraffin emulsion.—G. S. S.]

roots placed beyond and out of reach of the annual surface manuring. To such trees a good soaking of sewerage of any kind once or twice during winter would be of infinite value, because by this action some manurial elements are supplied that cannot reach them by any other means. Young trees already over-luxuriant in leaf growth need no such help. It would be wasteful and injurious to give manures in such a case, but those trees which are regular in bearing, whether young or old, would be materially benefited by two or three soakings during the winter. Raspberries, Strawberries, Gooseberries, Currants, Apples, Peas, Apricots, Plums, Peaches, or, indeed, any fruit-tree or plant may have this liquid food given them to advantage. Strawberries are strictly surface-rooting plants, and soon absorb much of the manurial properties from the soil, and even young plants put out so late as the autumn of last year would be favourably influenced by this manure irrigation, though, necessarily, the older plantations should be the first to be so favoured. Nor are fruit-trees the only subjects for which this food is adapted. The Asparagus-bed will at once afford an instance where similar aid would be both welcome and advantageous. Only those who have had recourse to the lifting of

Asparagus roots of long standing know the great extent there is of hungry, feeding roots, and the depth to which they burrow in search of fresh food. It would be a boon, undoubtedly, to many an Asparagus-bed to have two or three soakings of any kind of liquid-manure in winter, and the sooner this is done the better, for the presence of water from the recent rains would assist the passage of the richer liquid to the roots below. There is also the question of evaporation that suggests itself, the difference between that of January and March or April being very marked—at least, when typical weather is experienced in these months. We have seen wonderful changes wrought in the growth of Spring Cabbages following the application of liquids of this kind.

In dealing with liquid-manures, it is well to remember the kind and to use discretion. We should not apply the drainings from stables undiluted to the roots of any surface crop, because the ammonia in stable liquids is very powerful. Injury more than good might follow such a course. In the case of Cabbages and Strawberries, for instance, the manure would be better poured from the spout of a water-pot down the centre of the lines, and not close up to the plants. From here it would gravitate laterally to the roots, and the more easily when there is ample moisture already present in the soil. From the cow-yard and piggeries the liquid has not the burning influence, but in every case it is better to use discretion and avoid extremes. I feel convinced that very many readers of GARDENING ILLUSTRATED refrain from using such valuable aids to successful gardening from the feeling that in winter watering of the soil would be a wasteful effort, and the valuable contents of the receiving tanks are allowed to feed and pollute the nearest stream or river, while they would be so much better filtered through the garden soil. My advice then is, where practicable, to at once avert this waste by applying it to the land. It matters not what crop it may be growing, any kind would be benefited; but where there is the greatest poverty or the demand is most pressing is where it is of most value. W. S.

MELONS.

TOWARDS the end of January is a good time to sow for an early crop where a temperature of 65 degs. to 70 degs. can be maintained during the night, advancing to 80 degs. with sun heat during bright days. Fibrous loam, with a little leaf-soil, forms a good compost for the reception of the seeds, which should be sown in 2½-inch pots, placing two seeds in each, pulling out the weaker plant before the rough leaf is produced. The soil should be made firm in the pots before the seeds are sown and afterwards plunged in a propagating pit or in a cutting box filled with Cocoa-nut-fibre and stood over the pipes with a couple of bricks to carry the box. Here no water will be required until the seeds have germinated, and then great care must be exercised in the matter or the little plants soon succumb. Keep them near the glass roof, as if they once get elongated—that is, drawn up spindly—they seldom ripen a good crop. In the meantime get the house thoroughly washed down—glass, woodwork, etc.—the walls whitewashed, and the beds which are to take the plants, whether in pots or planted out, emptied of the old material and refilled with freshly gathered leaves, which will be found to give quite enough bottom-heat where hot-water pipes run underneath, which should be the case for early crops. In lieu of such, about half the material may be stable litter, mixing both well a couple of times within 14 days before putting in, and treading the pits very firmly. The surface of the bed or pot should not be more than 2 feet from the glass roof. In case the house should not be ready by the time the plants are fit, repot into 5-inch, warming the soil first. Good holding loam, with a little bone-meal or wood-ashes, makes a good compost for the Melon, and this must be made very firm. Do not plant deep, not deeper than when in the small pot, but press the soil firmly around the ball of roots without disturbing the same, and do not apply water for a few days. If it is intended to carry up a single cordon, plant 20 inches asunder, or if two stems be chosen 30 inches will be none too much from plant to plant, and

these must be pinched at the second true leaf a week before or after planting out. No stopping of the main shoots should take place until within 6 inches of the allotted bead room, but the laterals or side shoots at the base may be stopped at the first leaf. These will push out others, and some show a female blossom which will be open about the same time as those on laterals further up the trolis, and should be fertilised at the same time, if possible—at any rate, not more than a day must intervene or the fruits will not swell away together. The plants should be syringed twice daily up to the time they show fruit, then discontinue until a set has been secured. When the fruits are swelling a fair amount of water at the root is necessary, keeping it away from the stem or canker will be the result. Weak guano water twice or thrice a week will prove beneficial, and do not over crop. Two to four fruits are ample for early crops, and these must be supported in good time with square pieces of board wired at each corner. EAST DEVON.

VALUE OF SEAWEED FOR FRUIT-TREES.

I SHOULD be glad if you would give me information on the two following questions:—1, Is seaweed a good manure for all garden produce and orchard?—2, What is the best method of dealing with and applying Seaweed?—L. W. BENNETT, Killeena, Co. Cork.

[Seaweed for various garden crops is seldom used so freely as it might be, especially by those whose gardens are situated near to the coast. Many, no doubt, in the midlands would be only too pleased to lay in a store for Asparagus and Seakale plantations, but the distance entails too much outlay for Seaweed to be used generally for such purposes, while others who can obtain large quantities for the mere cost of carting appear to ignore its value. Those who have not tried Seaweed in their orchards or fruit gardens would be surprised at the beneficial effect it has on the trees, especially Apples and Pears, whom, of course, it is used with care and moderation. This is particularly the case during dry seasons. My first impression—and it was not a slight one—was gained at Bembridge, Isle of Wight, on land reclaimed from the sea. The soil is undoubtedly to a great extent composed of thoroughly decayed Seaweed and sand, and the way all vegetation appears to thrive in it is marvellous; and it occurred to me that for light soils and for use during a very dry season Seaweed would undoubtedly prove more valuable as a mulch than any other material generally used for the purpose. Apart from any manurial properties it contains, it is, like salt, moisture-holding as well as feeding, the value and importance of which should not be ignored by those whose fruit-trees are growing in too porous soils and where the rainfall is light. I certainly never saw more healthy trees, or better samples of Apples, though, of course, the climate and situation are also very favourable for their production. I should not advise burying fresh Seaweed near to the roots of established trees or incorporating it with the soil in forming a new orchard or fruit garden, but frequent mulchings of the surface ground are, I am sure, a safe means of stimulating growth and sustaining the trees under the trying influence of a long drought. By this means it would gradually find its way into the lower stratum, and undoubtedly improve its staple.

These views were further strengthened when recently visiting a large garden in Sussex. In these gardens the outdoor culture both of Peaches and Nectarines is gone in for largely, the grand walls and mild climates proving very favourable to their well-doing. Some of the borders are on rather sharp slopes, causing rain to run off freely and the work of watering thoroughly somewhat difficult. For many years the gardener resorted to heavy mulchings of stable litter, not only round the trees themselves, but also all over the borders, which are usually cropped with something dwarf, such as French Beans, etc. The effect of this was that it not only formed a harbour for sparrows and other birds, but, what was worse, woodlice, earwigs, weevils, and beetles found it a safe lurking-place by day, while they made the softening fruit of Peaches and Nectarines on the walls their feeding-ground at night. Many fine fruits were therefore entirely spoiled before they were ripe, and had to be used in the

kitchen. No finer fruit could possibly be seen than on these walls at the time of my visit, large, bright, and without a speck, and, what is more, each fruit ripened perfectly without any damage by the pests named above. Seaweed was used in the place of stable-manure for mulching.

Seaweed varies considerably, some being far too coarse and heavy for the different purposes mentioned above, unless it has first had sufficient time for partial decomposition. Preference is given to that of a finer and lighter character, which when collected generally contains a fair amount of sand, making it more suitable in every way for use in the garden.—P.]

NOTES AND REPLIES.

Apple Franklin's Golden Pippin.—Though not very large, this Apple is generally much appreciated for its brisk aromatic flavour and on account of its yellowish-white flesh being always juicy and crisp eating. As many are no doubt aware, the colour of the fruits is deep golden-yellow, and the skin is irregularly dotted with small dark brown spots, but differing from Old Golden Pippin in being slightly larger and less conical in form. It is a first-rate dessert fruit, and the tree may be successfully grown either as a bush, pyramid, espalier, or orchard standard.—A. W.

Plums falling.—Three seasons ago I purchased a garden containing, with other things, two Plum-trees, not over large, and each season both have had a very heavy supply of blossom, which in turn set for Plums, but when the size of Beans they all fall off, with the result that only six Plums of two trees ripened. Can you suggest a remedy for this?—W. P.

[Yours is a case of too much root growth. The roots are probably too deep, and your best plan will be to lift the trees, cut back the strong roots, and replant nearer the surface, covering with a moderate thickness of short manure. October is the best month to do this, but having missed that month do so at once. Give the trees when replanting burnt garden refuse, some lime rubble, and turfy soil from a meadow—say a barrowload to each tree. Cover the soil with rich manure in May, and water freely when the fruit has set.]

Grapes cracking.—Will you please advise me how to treat my Grape-Vine, a round white Muscat? It is in a greenhouse facing S.S.E., with the roots outside. I believe the Vine is about 30 years old, but two years ago it was cut back, and now there is nothing but new wood on the Vine. It always bears a good quantity of Grapes, and the bunches are well formed; but when nearly ripe the fruit cracks, and then goes mouldy. The house is not artificially heated, and there is plenty of ventilation—a door at either end, front lights, and three top lights—A. K. C.

[Extremes either of atmospheric or root moisture are common causes of Grapes cracking, brought about by irregular ventilating or a heavy watering when the border has been allowed to get dry previously. White Grapes are much given to this failing, some kinds more than others, due, perhaps, somewhat to the thinness of their skins. They can, however, be successfully produced without the trouble complained of provided the requisite treatment is given. At the time of ripening many good gardeners make a point of never closing the roof ventilators quite close, but leave sufficient air on at all times to allow moist air to pass off. You are placed in some difficulty in not having a heating apparatus. This may not be needed in regular use; but should the season be wet and unless, like that of last year, there are periods when a little fire-heat keeps Grapes more safely. Possibly you have erred in thinking your crop safer with closed ventilators in doubtful weather. Should this have been your practice, then a remedy is easily devised. Even when it rains, if the ventilators are so constructed as to exclude rain, they are best left a little open, and on no account shut them down when there are sun and moisture enough in the house to cause excessive humidity to rise. In catchy weather it is most treacherous to close the house during the day; a sudden outburst of sunshine is sure to burst the Grape skins. The same rule applies to the border. Aim to keep up an even state of moisture, and never let it become dry. A heavy watering or a thunderstorm following a dry state of the soil ruptures any thin-skinned Grapes by reason of the undue expansion caused by a sudden rush

VEGETABLES.

BORECOLE OR KALE.

THERE are few more hardy and generally serviceable vegetables than Borecole or Kale. Room for one or several forms ought to be found in every well-managed garden, and if not actually considered a high-class vegetable, Kale cannot well be dispensed with. In very severe winters, Broccoli, Savoys, and not unfrequently Brussels Sprouts are badly injured by frosts, but it is not often the Borecoles are destroyed, some of the varieties being nearly as hardy as it is possible for a green succulent vegetable to be. Their culture and requirements are of the simplest character. As a rule, late in April or the first week in May is quite soon enough to sow the seed. If raised much earlier the plants become starved and leggy in the seed-beds, and such cannot reasonably be expected to do so well as the sturdier later raised batches. Naturally, the earlier the plants are established where they are to grow to their full size, the stronger and more productive they become. A few only are able to give a piece of ground wholly up to this crop, and the plants must therefore be either planted between rows of early Potatoes, or else be put out in close succession to these and any other early

been much injured by cold winds or frost, and is most valuable for affording a supply of succulent Greens after all the rest have run to seed. When Broccoli, Cabbage, and other Kales have been much cut up by frosts, a good breadth of the sturdy-growing Asparagus Kale is invaluable. I.

FORCING RHUBARB AND SEAKALE.

(REPLY TO "RHUBARB.")

As it is evident you want to force both Rhubarb and Seakale largely and for a long season, your first duty must be to secure good stocks of each. To that end, and with but at present a dozen roots of Rhubarb, you had better either buy in two or three dozen more roots and plant them at once on well-trenched and manured soil, 4 feet apart each way, or else lift your present roots, divide them into portions having each but one or two crowns, with some root attached to each, and plant those as before advised. Roots of Rhubarb for forcing should be large, from three to four years old, having some nine to twelve good crowns. After being forced these may be divided and replanted to increase the stock. To have plenty of roots it is needful to plant some every year, and so keep up a succession. To make up a forcing-bed, have the stable-

for forcing can be had in plenty by sowing seed in shallow drills 2 inches apart on trenched or well-manured soil in April, later thinning the plants out to 12 inches apart, and keeping them clean through the summer. In the winter, after all the leaves have decayed, the roots can be lifted carefully, all side ones hard trimmed off and put aside to make root cuttings for the following year's stock, then the roots laid in thickly into the ground ready for use as required.

NOTES AND REPLIES.

Coloriac failing.—I would like to know why my Coloriac has failed? The plants have been put 1 foot apart in sandy soil, which was previously manured, and once during the season watered with nitrate of soda in weak solution. The plants were abundant in leaf, but no roots. Those not watered with nitrate of soda were the same. —*HENRI FROEL.*

[The growth of Coloriac does not, as a rule, present much difficulty. February or March is the time for sowing the seeds in boxes or pans, choosing finely-sifted soil, mixed with decayed manure or leaf-mould to the extent of about one-third of its bulk. Prick out the seedlings as they become sufficiently advanced in a warm-house or pit into other boxes not more than 2½ inches deep, over the bottoms of which are spread leaves or Mushroom-bed-manure for drainage. Similar soil to that used for sowing is advised for pricking out, and moisture should be afforded as often as necessary, bearing in mind that dryness at the root is inimical to the progress of this vegetable at any stage of its growth. For planting in the garden, choose either ground deeply dug and well manured or dig shallow trenches about a spade's depth and place a layer of good manure at the bottom, filling them in nearly, but not quite, to the top with soil. This depression will allow of watering being carried out easily in summer-time. If planted on dug ground, only just draw a deep drill with the hoe to plant in; this also will leave space for watering. Unlike Celery, it requires no earthing up. Liquid-manure, given when well established, is beneficial.]

Manuring a shallow soil.—Having a very dry, shallow, sandy soil, only a few inches in depth, I have just "bastard trenched" a part for vegetables, turning out the top spit, stirring the subsoil (sand), and laying a heavy thickness of green cow-manure on that, and the top soil above it. As there are only a few inches of soil above the manure, I am anxious to know what vegetables would be the most likely to succeed under the circumstances? I suppose it will be too gross for some, and as there is not much ground, I wish what is put in to succeed. It is a somewhat bleak and windy place. So far, I have decided on French Beans, Leeks, perhaps Onions, Parsley, Beet (Celery and Lettuce are otherwise provided for), and Potatoes. Peas are not desired. Your advice in *GARDENING ILLUSTRATED* will much oblige, also whether next winter I would be justified in double trenching it, though the subsoil is so poor? —*DUMBY.*

[It would have been better could you have buried your heavy dressing of cow-manure deeper than just a few inches under the surface. No doubt crops will, up to a certain stage, once the roots penetrate into the manure, grow rapidly and perhaps grossly, but they will soon be checkmated, should the weather prove dry, by heat and drought. Had you forked in and mixed the dressing of manure with the lower or subsoil, so as to have buried it deeper, poor as that soil may be, the roots would have gone down in search of the manure, and they would have withstood drought so much the longer. You will, however, be justified in having any garden crops on the ground, those named, also Cabbages, Turnips, Winter Greens, etc., but how they may thrive will chiefly depend on the nature of the season, whether it be dry or moist. Next winter bastard trench it 20 inches deep, and work a good dressing of manure into the bottom or subsoil in the process. Also later fork into the top soil a dressing of well-decayed manure. Then it will carry good crops.]

Parsley.—Where the supply is getting short, a little seed should be sown in a box of light soil and placed in a temperature of 50 degs. As soon as germinated, place near the glass, and when fit to handle transfer to other boxes 2 inches apart, and gradually inure to colder quarters, eventually planting out towards the end of March, taking care of the tap-like root. Old crowns may be lifted and potted up, and, if placed in a vinery or Peach-house just closed, and lightly syringed once or twice daily, new growth will soon push up. Frost does not appear to eat up Parsley so

True Scotch Kale.

vegetables. Breadths planted as late as the end of August will sometimes attain a serviceable size, especially when the autumn is comparatively warm, and therefore favourable to late growth. They pay well for having moderately rich ground and good room, the produce of plants growing on poor soil being light and also poor in quality.

SCOTCH OR CURLED KALE is, perhaps, the most popular variety in cultivation, more plants of this being grown probably than of all the rest put together. There may be others more hardy and productive, but in point of quality all are inferior to it. There are very finely curled forms of both the tall and dwarf Scotch Kale, and as far as productiveness, hardiness, and quality are concerned, there is not much to choose between them, all producing good greens after the heart has been cut.

READ'S IMPROVED HEARTING is a decided advance upon the ordinary forms, this producing a heart almost equal to a Savoy Cabbage, and milder in flavour and more tender when cooked. Unfortunately, the hearts when fully grown are not so hardy as desirable, and these ought, in consequence, to be protected in some way whenever a severe frost is anticipated. It is not advisable to lift and store this Kale, as a serviceable crop of side shoots is produced in the spring.

ASPARAGUS KALE has never in my experience

manure put into a large heap, turn it weekly some three or four times to prevent fermentation, moistening it as it shows signs of becoming dry. Then make up a bed in any shed where there is room. A bed 5 feet by 8 feet, and when well trodden 18 inches deep, should give ample room for twelve to fifteen large roots at a time. Put a layer of 2 inches of soil on the manure, then place the roots close together, fill in with soil, water, and cover up to keep dark with mats fixed 2 feet above the crowns. During the winter, to keep up a supply, three or four such beds may be needful. If all this is too much labour, then place tubs without bottoms over the Rhubarb roots outdoors, use movable tops, and coat the tubs all round thickly with warm manure. That helps to bring on growth fairly early. Rhubarb plants can be raised from seed sown in shallow drills in April, but purchased roots of Champagne are best.

Seakale has to be forced on beds in the same way, but smaller ones, as the roots can be atood in the beds 3 inches apart. As Seakale to be edible must be fully blanched, it is essential that the growths from the crowns, which soon follow when thus forced, be quite in the dark. Close covered cupboards or beds with wooden sides, 12 inches higher than the crowns, and covered with a dense, close cover of some sort can be put to exclude light, are essential. Seakale

badly as cold, piercing winds; therefore, when planting to withstand the winter, choose a warm, sheltered corner for at least part of the crop.—J. M. B.

GARDEN WORK.

Conservatory.—We have still a few blooms of late-flowering Chrysanthemums left, and very useful they are, especially for cutting. Cuttings are still being taken, though, of course, all the early cuttings are rooted. But this time, or even later, is time enough to take cuttings for decoration—in fact, cuttings for late-blooming and small pot work will be taken months hence. It is best to place them where they can get a little warmth. When the rooting lingers it has a weakening effect upon the plants. Where only a few plants are wanted, strike in small pots singly, but when grown in a wholesale way strike in shallow boxes in light sandy soil, and pot off as soon as rooted. Cuttings of the young shoots of Fuchsias, when 2 inches or 3 inches long, will strike quickly in bottom-heat now. Old plants should be pruned into shape, and placed in heat to start them into growth, and as soon as the young shoots are fairly started, shake out and repot, still keeping the plants in heat and using the syringe freely on fine days. Fuchsias planted out in the conservatory are very ornamental, if free-growing kinds are selected. They may be trained up the rafters or treated as pyramids or standards. For the most part the plants will have been pruned back now, and when they break, any shoots which show a tendency to run away and become robbers should be pinched, so that all the shoots may come away together and form a symmetrical head. More freedom may be permitted later. The Acacias, even in a cool-house, will now be in flower. A Drummondii, a dwarf species, is very effective now. After flowering, prune back more or less according to the condition of the plants. The first Coleus I remember was introduced many years ago under the generic name of Plectanthera. The latest are recent introductions from Central Africa, and are named Coleus thyrsoideus and C. Mahoni respectively. The former has blue flowers and will probably be found the more useful for the conservatory. They are not difficult to cultivate. Cuttings root easily in spring, and the same treatment which suits the winter-flowering Salvia will produce sturdy flowering plants of these new Coleuses. I anticipate there will be a large demand for them, as they bloom at a time when flowers are scarce. Arum Lilies coming into flower will benefit from frequent applications of liquid-manure. A good group of these will be a special feature now.

Stove.—Most people who grow Orchids will have a few in bloom now, including Cypripediums, Dendrobiums, Calanthes, and others which are not difficult to grow. The chief difficulty with inexperienced growers is the selection of the potting material, which should consist of the best fibrous peat and Sphagnum Moss, with fragments of charcoal, and in some instances dried flakes of cow-manure. The drainage also should be of the freest character. Special pots, pans, and boxes are made for Orchids, and these should be used for most of the species, though Cypripediums, Dendrobium nobile, and others of the terrestrial species do fairly well in ordinary pots when well drained and the potting material of a rough and fibrous nature. The season is at hand when the general collection of stove plants, especially the summer-flowering things such as Allamandas, etc., should be repotted. It is not advisable to use pots of too large a size, as if the drainage is right, liquid-manure may be used freely when the dower-buds appear. In dealing with plants now in large pots, some reduction of the bells may be made so that the plants may again go into the same sized pot, though this should either be new or thoroughly scrubbed out and made clean and sweet. Fine-leaved plants, such as Antirrhinums, Marantas, etc., may now be repotted, and if an increase of stock is required the root-crowns may be divided. In the Eucharis Lilies require repotting this is a suitable time, though so long as the bulb have room in the pot to grow there is no need

for it, as by a free use of liquid-manure the bulbs will flower very freely when potted. The same treatment will suit Clivias or Himantophyllums, which are usually brought forward in the cool stove till flower-spikes appear, and then moved to the conservatory. Night temperature 60 degs. or a little more. Air to be given at 75 degs. to 80 degs.

Cucumbers.—Plants which have been in bearing most of the winter will require very careful management now, especially as regards freedom from insects and mildew. Green-fly can easily be kept under by using the vaporiser occasionally. Red-spider should never be permitted to enter the Cucumber-house, and, if there, may be got rid of by using more moisture in the atmosphere and damping down with guano-water or liquid-manure in some other form. Of course, whatever is used should be very weak, as a strong dose of ammonia might injure the foliage. Another matter which demands attention now is the necessity for frequent light top-dressing of warm, rich soil. There must, of course, be a comfortable bottom-heat, and for the present, at least, very little ventilation will be required, as no glasshouse is altogether airtight. New houses may be planted in succession, and those who grow their Cucumbers on hot-beds in frames may now make up their beds, beginning first, unless there is a spare propagating-house, with a bed for raising the plants.

Disbudding early Peaches.—As soon as the fruit is set and swelling the regulation and thinning of the young wood will require attention. This is best done in a tentative manner, so that no check may be given. When this work is done there should be one shoot near the base of each bearing shoot, and to each of the latter a leader must be left, though this may be stopped later in the season if necessary to avoid over-crowding, but the shoot near the base is the really important one, and should be trained in unstopped. Some of the young fruits may be taken off when crowded, especially from the underside of the branches, but the time for the final thinning is not yet. Maintain a general atmosphere in the house, either by syringing or damping borders and paths. Liquid-manure may be given with the chill off when the borders are dry.

Window gardening.—Watering is the most important work at this season. The days are lengthening, and plants in pots will require more water, especially where the plants have plenty of roots. Genistas, being full of roots, may have a little weak liquid-manure occasionally. One reason why these plants often fail in a room is, they do not get sufficient nourishment, and the flowers drop off and the leaves lose colour. The same thing occurs with Heaths and Acacias, though the latter are not difficult to manage.

Outdoor garden.—Now that the frost has left for the time being, all recently planted things, especially small things, should be gone over and the soil made firm round the collars. It will, of course, be better to wait till the surface is getting dry before treading on the land, especially if the soil is of a heavy, adhesive nature. With mild weather very often come the snails and slugs, and they have a way of secreting themselves just under the soil round the collar of such things as Pyrethrums, Phloxes, etc., and they generally are more troublesome among the choicer, delicate varieties. The best protection in the case of individual plants is a circle of ashes placed round early in the autumn before the snails take up their quarters to wait for the starting of the young shoots. Where Tea Roses or other tender plants have been sheltered by a small mound of dry earth, ashes, or Cocoa-nut-fibre, the frost has done no harm. All kinds of planting may be done and works of improvement carried out. There is much to interest one in making alterations, especially in creating new features. Every man, whether owner or gardener, has some kind of desire to leave his mark upon the place which has given him shelter and employment for a number of years, and there is plenty of work to be done.

Fruit garden.—Any Peaches not yet pruned and washed should have attention. Do not crowd the branches. A healthy tree will

always, in an average season, set more fruits than can be left to ripen, and if the bearing branches are trained at an average distance of 6 inches, there will be plenty of fruits to take off, and, what is of equal importance, there will be ample space to train in the young wood that will bear the next year's crops. There are two evils the Peach grower must guard against, and these are—leaving on too much wood, and permitting the green-fly to get established among the foliage before taking measures for their destruction. The best and cheapest remedy for green or black-fly on Peaches outside is Tobeco-powder. Under glass the vaporiser can be used, and this makes short work of all kinds of aphides. The pruning of Nuts and Filberts is generally left till after the male and female blossoms appear, for the purpose of leaving the catkins or male blossoms for fertilisation. Nuts are generally pruned so as to leave the centre open and surrounded with feathery spray, which bears freely. All suckers are removed from main stems. It is too early yet to altogether uncover Figs on walls, but the covering may be thinned to let the air circulate freely. Keep up a succession of forced Strawberries by introducing relays of plants.

Vegetable garden.—The sowing of early crops on the warm south border will be seasonable any time now when the soil is in a workable condition, but I have no sympathy with those who have fixed days for sowing any particular crop. At the same time those who take advantage of the weather will find suitable opportunities to sow the various crops, so that they may come in at their time. Prepare the ground for Onions, so that they may go in towards the end of the month or early in March. Many of the best grown sow at least a part of the crop in boxes under glass and plant out early in April. Early Peas and Beans are also started in several ways under glass to supplement the crops sown outside to make things sure. Cauliflowers, Leeks, and Brussels Sprouts should also be started in a small measure under glass, the Cauliflowers in heat, and the others cooler to come on steadily. Hot-beds may be made up for Cucumbers and Melons any time now. Cabbage plants and Lettuces standing in the seed-beds may be set out to succeed those planted in autumn. The manure that was wheeled on the land during the frost may now be dug or trenched in, though, as far as possible, trenching should be done in autumn or early in the winter to give time for the weather to act upon it, and for consolidation. E. HOBDAK.

THE COMING WEEK'S WORK

Extracts from a Garden Diary.

February 20th.—Sowed Cauliflowers in heat. After a mild winter the early autumn sown plants, or some of them, may bolt prematurely, but these spring raised plants if grown on unchecked always do well. Finished washing and training Peaches on walls. The crop is taken from young wood only, not spurs, and this is trained at rather wide intervals to leave plenty of room for the young wood of the present season. Strong ripe shoots have been collected and laid now on north aspect to be ready for grafting.

February 10th.—Cuttings of various plants are being taken and propagated in heat. All plants from which cuttings are taken have been warmed up a little to ensure fresh young shoots for cuttings. Sowed early Long-pod Beans outside, also more early Peas, including Gredus, which does well with us. Both Peas and Beans are to a limited extent started under glass, as no means of securing an early crop must be neglected. Mustard and Cress are sown regularly in heat.

February 11th.—As fast as Asparagus is cleared from the forcing beds a few inches of good loam are mixed with the lighter soil in the frames, and Potatoes which have been already started are planted. In one frame Lettuces have been sown. These will be thinned out, and some transplanted elsewhere. To my mind there is no Lettuce equal to a frame-grown Lettuce in the early spring. Abundance of ventilation will be given when needed. Begonia tubera which have been packed in Cocoa-fibre have been started in heat.

February 12th.—More cuttings of Chrysanthemums are being put in; of course, most of the cuttings required to produce big flowers are rooted, but the number of these has been reduced, and more attention will be given to moderate-sized blossoms, and there is time enough for cuttings of these yet. March is soon enough for late kinds. Peaches under glass, where the Peaches are set, have been gone over and a few young shoots thinned, and badly placed fruits removed. Syringe is used freely now on fine days.

February 13th.—Planted a warm-pit with No 1 Plus Ultra French Beans to succeed those coming on in houses. Strawberries in blossom are looked over daily, using a rabbit's-tail to fertilize the blossoms until enough are set and swelling for a crop, and then all small fruit and late blossoms are removed. A little stick is placed to support each cluster of fruits to keep them off the soil and away from the taints of any liquid-manure which may be used. Sowed more Cucumber and Malon-seed.

February 14th.—Moved Onions raised in boxes to cool-frame to harden. More Rhubarb and Seakale have been moved to Mushroom-house. Early Rhubarb is now moving outside under tubs and pots without heat other than that obtained from the sun. A new plantation of Rhubarb has been made to obtain roots in due time for forcing. A piece of land has been got ready for planting Seakale cuttings or thongs taken from crowns lifted for forcing, and which have been laid in sand and are now forcing crowns.

POULTRY.

The Indian Runner Duck.—Where a free range can be had, this Duck is unequalled as an egg producer. Commencing to lay at an early age (between five and six months), it continues regularly right through the autumn and winter, even during the coldest weather. Being particularly hardy, both the ducklings and the mature birds thrive wherever they have their liberty; in confinement, however, they do not succeed. This species will obtain the greater part of its living, being an excellent forager, roaming about all day in search of worms and slugs. The young ones get their adult plumage at about six weeks of age, and mature so quickly that they are ready for table at about eight weeks. This is not a large Duck, but, being small in bone, has plenty of meat on the breast, and the flesh is of fine flavour. The eggs of this bird are large, considering its size. Pure bred Indian Runners have a long neck; the head bronzy-green, with a narrow line of white encircling the base of the beak at its junction with the head; shoulder, back, and breast fawn, the upper part of the drake's breast being tinged with reddish-brown, while that of the female is dark brown, the feathers being edged with fawn. The wings are white, the legs orange-red, and the beak dark green. When on the move this bird runs very fast, holds itself very upright, and has not the waddle so characteristic of most waterfowl.—(J. S. S.)

BIRDS.

BREEDING FOREIGN BIRDS.

(REPLY TO "QUERIST.")

BUDGERIGARS are, perhaps, the most satisfactory kind of foreign birds to breed in confinement, being very hardy and always doing well in an outdoor aviary. They are natives of South Australia, and belong to the Parrot family, but are quite small, the body not being really much larger than that of a Canary, although its long tail gives it quite a different appearance. The plumage is bright green, the back and wings being marked with dark, undulating lines, the fore part of the head light yellow, while the naked skin about the beak is sky-blue in the male and cream colour in the female, excepting at nesting time, when it assumes a brown tint. They do not usually commence breeding till August—that is, after they have moulted, and frequently continue to rear broods till quite into December. The eggs vary in number up to eight or nine, and are hatched in about sixteen days but in succession, as the hen sits on the

time of laying the first egg. Oats and soaked bread are added to the usual diet when there are young ones to be reared, the ordinary food for the adult birds being Canary-seed and Millet. These birds require no hiding materials, but will readily take to a Cocoa-nut husk in which to lay and rear their young if provided for them, being suspended or placed in a snug corner with the aperture at one end turned towards the light. A very free breeder in the aviary is the Orange-cheeked Waxbill, a charming little bird, its general colour being brown on the upper parts, and greyish-white underneath, the feathers on the rump are red, and the tail nearly black, while a reddish-orange patch surrounds the eye; the legs and feet of a flesh tint. The nest is readily constructed in the nearest available receptacle, be it a nest box, small cage, Cocoa-nut husk, or shrub. The young are reared upon ants'-eggs, and the old birds subsist for the most part on Millet. The pretty Zebra Finch with its purple-spotted sides, chestnut-coloured ear-patches, and coral-red beak, also breeds very freely in confinement, producing three or four broods in the season. Another free breeder in the aviary is the Java Sparrow. It produces two or three broods during the breeding season, and the young are reared upon fresh bread-and-milk and ants'-eggs, the diet of the old birds being Millet and Canary-seed. There are two varieties of this species—the leaden-blue and the white. Cardinals are satisfactory aviary birds and breed freely, but should be allowed the whole of the aviary to themselves, as they are very quarrelsome during the breeding season, and any companions in the aviary weaker than themselves are liable to be very much persecuted. The Cardinal rears two broods in the season, the young varying from three to five in number, and are easily reared on ants'-eggs and insects of any kind, but require a great quantity of food. It is well to furnish the aviary containing these birds with two or three pot shrubs, such as Box or Fir, as in these they will construct their nests. The food of the adult birds should consist of Millet and Canary-seed in addition to insects, ants'-eggs, and ripe fruit. S. S. G.

LAW AND CUSTOM.

A gardener's contract (K. C.).—You were engaged as gardener at 2s. a week, but your wages have since been raised to 2s. a week. No house was provided by your employer and you rented a house from a third party. Your employer has now purchased a house for his gardener, and the purchase was completed on Saturday, January 3rd. The same day he told you to move into the house on Monday the 5th, but it seems that you have not yet moved. You say you shall not be able to move for some time "because the tenant who is in the house has six weeks' notice." I do not exactly know what this expression means, but if it means that the present tenant of the house your master has purchased is under notice to quit, but that the notice will not expire for six weeks, it is clear that you cannot remove into the house until the tenant goes out. And no matter whether he is under notice or not, you cannot be compelled to attempt to enter until he has gone out. It is no part of your business to get him out—that is your master's affair. You say that there is an agreement that your wages shall be reduced to 1l per week, and that you are to have the house rent free, and that although you have not yet got possession, your master has stopped 4s. a week, and has paid only 2s. a week. But he cannot do this, and until such time as he can give you possession he must pay you 2s. a week. He may, of course, give you notice to determine your service, and on its expiration you and he may enter into a new contract on any terms agreed upon; but until he can give you possession of the house, or until he determines the existing contract by proper notice, he must continue to pay 2s. a week. There is a further matter which may be of importance: your master must allow you time to determine the tenancy of the house you occupy if he did not give you sufficient notice before January 3rd. I do not know what previous intimation you have had, but until such time as you are displaced as would be necessary for

the determination of your own tenancy by a notice given for that purpose as soon as you received the intimation from your employer, no deduction from your wages can be made. But, of course, if your employer has given you notice to determine your service, and that notice has expired, or if you and he have entered into a new agreement, the preceding answer does not apply.—K. C. T.

CORRESPONDENCE.

Questions.—Queries and answers are inserted in *Gardening Illustrated* free of charge if correspondents follow these rules: All communications should be clearly and concisely written on one side of the paper only, and addressed to the Editor of *Gardening Illustrated*, 17, Pall Mall, London, E.C. Letters on business should be sent to the Publishers. The name and address of the sender are required in addition to any designation he may desire to be used in the paper. When more than one query is sent, each should be on a separate leaf of paper, and not more than three queries should be sent at a time. Correspondents should bear in mind that, as *Gardening Illustrated* has to be sent to press some time in advance of date, queries cannot always be replied to in the terms immediately following the receipt of their communication. We do not reply to queries by post.

Naming fruit.—Readers who desire our help in naming fruit should bear in mind that several specimens in different stages of colour and size of the same kind greatly assist in its determination. We have received from several correspondents single specimens of fruits for naming, these in many cases being unripe and otherwise poor. The difference between varieties of fruits are, in many cases, so trying that it is necessary that three specimens of each kind should be sent. We can undertake to name only four varieties at a time, and these only when the above directions are observed.

PLANTS AND FLOWERS.

Removing paint from glass (East Hilywell).—You can remove this either with a cloth dipped in turpentine and rubbed over the paint or with strong pearlash, such as is used for cleaning printing type. If turpentine is used the glass will need cleaning afterwards with water in which a little washing soda has been dissolved.

Pot Roses not flowering (Chester).—It is possible the growths are what is known as "blind"—that is, they will not blossom until succeeded by another growth. But it is rather early to say for certain that the present young growths are flowerless. You must not prune them just yet—wait until the young wood has become firm. When you observe the topmost eyes or buds commence to start out into growth, and no flower-buds appear, then will be a good time to cut back the shoots, say to about 9 inches from their base. Do not replot again until the summer-time.

Roses from cuttings (Roma White).—If you have such a thing as a frame or bed of leaves where a gentle heat can be maintained, the cuttings could be potted in March into small 60 pots and plunged in Coolin Glass-house refuse in such a frame. Some of the cuttings may only have the white wax-like substance at base, which is termed "callus," and from which roots eventually appear. This gentle bottom-heat would be of great assistance to such. A slight syringing over each fine day would be of much help to the plants, but water at the roots must be very carefully applied, and when it is given it should be made lukewarm. The plants could be planted out from the pots in May or June.

Carnation spot (Mabel Hilywell and Lady L. Egerton).—Your Carnations have been attacked by what is known as "spot" due to a fungible soil or overcropping. This latter being evidently the cause in the case of your plants. No cure has as yet been found for it. Cut off all the diseased leaves and burn them; in fact, we should not hesitate to pull up such plants as the ones you send and at once burn it. Growing the plants for two years in one place is a mistake, as Carnations ought to be fresh ground every year, or, at all events, the soil be renewed before replanting. The spot is always worst in a wet, cold season, and the Old Clove is very liable to its attacks.

Growing plants (A. B.).—Almost impossible to answer in a satisfactory manner, and your better way would be to get some practical gardener to see your plants and advise thereon. With regard to the watering, the plants should not only be watered when they require it, and then enough must be given to thoroughly wet the ball of earth. On no account must any water be allowed to stand in the saucer, as this keeps the soil in a sodden condition. Let the plants have as much light as possible. Potting is best done in the spring. Soil composed of equal parts of good loam and leaf-mould, with a quart of a part of sand, will suit all the plants you mention. Cut off all withered leaves and dead shoots. No fertilizer of any kind should be used unless the roots of the plants are in a healthy condition, and yours are scarcely likely to be in that state.

Manuring garden ground (W. K.).—Common Buck is a poor manure, and seaweed, if half-decayed, is a fair manure. But in using these things it is wisest to mix them in a heap, turning them two or three times at intervals of a month, and at each turning adding a good amount of soot. At the final turning, which should be a couple of weeks before using, add to each cartload 12 lb. of bone flour (phosphate) and the same of kainit (potash). If that be well mixed with the heap when finally turned it rapidly incorporates with it, and then the whole may be dressed on the ground at the rate of a cartload to each 3 rods of ground. But where artificial manure alone is used, especially in flower borders, the proportion of 8 lb. of the two manures named, forked in and at once, is not too much. But with that give 5 lb. of nitrate of soda per rod in the spring—say, end of May or in June. Plants cannot walk take up more than a certain proportion of manure, the rest being so far waste. Give the ground a good dressing of stable manure once in three years if you

FAMOUS FOR 110 YEARS.

MAGNIFICENT HARDY PERENNIALS AND SPRING-FLOWERING PLANTS.

TO FLOWER THIS YEAR. VEGETABLE & STRAWBERRY PLANTS.

All grown and wintered in the open field, and are exceptionally strong and healthy; best strains procurable, carefully packed, and guaranteed to arrive in excellent condition. If not satisfied, money willingly returned. Plants are at once sent back. Purchasers can divide to their themselves. Liberal discount. Cash with order.

Table listing various plants and their prices, including Gaillardia grandiflora, Coreopsis grandiflora, and others.

Names of plants. A Subscriber. Kindly send your specimens with numbers affixed to each, otherwise it is impossible to distinguish them. Catalogues received. W. Walters, 10, Water Lane, Ct. Goody, Bulchamp Paul, Clare, Suffolk. Latest seedling.

MRS. P. M. DELPH HOUSE, PETERBOROUGH.

Cleaning weedy lawn ground (Myrrhis).—As you say it is not possible to lay your proposed lawn ground mowed and the crop on it dug in with the manure deeply, your only course to fit the ground to receive Grass seed. In April—which was, we believe, the purpose of your original question—is to have all the weeds now on it pulled or hoed, then cleared off, and the surface just pointed a couple of inches to break it well and fine, leaving it fallow, when any surface weed seeds will soon germinate. When growth has resulted have all hoed over and the weeds removed, then re-hoe as deep as possible again, and at once sow Grass seed. That should be done end of April. If with that you sow, at the rate of 2 lb. per rod, finely crushed sulphate of ammonia, obtained from the gas works, the Grass growth should be very quick, and no doubt then would smother any weeds that might grow later. It is unfortunate that your ground is so foul with weeds, and turning would in your case be the safer mode of forming a lawn.

Plants for rock garden (K. P.).—Quite a large number of plants of the free-growing sort are not at all fastidious, such, for instance, as the whole family of Aubrietias, a large number of the dwarf Campanulas, a variety of Gentiana, while such as G. scutellipidea and G. Andrewsii prefer a moister place and some shade also. You could, however, make a feature of Sempervivum, Sedums, Saxifrage of several sections, the dwarf Irises, such as pumila, nudicaulis, obtensis, stylosa, and a few of the bulbous Irises, which cannot now be planted, as the season is too far advanced. Other suitable things may be found in the dwarf Phloxes, the alpine Pinks, alpine Poppies and Polygona, Megacaea, Arnebia, Thymus, Iberis, Tropaeolum polyphyllum, Arenarias, alba, Aster, Geopharas, Anemones in variety, Adonis, a selection of hardy Opuntias, Helianthemums, Scillas, Chionodoxa, Snow-drops, Muscaris, and in the autumn will produce a fine effect in the early spring months. All this, however, depends upon the extent of the work, and of this we have no information.

Chrysanthemums Mrs. H. Weeks and R. Hooper Pearson as bush plants for late display (H. P. M. S.).—The former is a very late-flowering kind, while the latter is a mid-season or November-flowering variety. As you desire to make bushy plants, you should insert the cuttings without delay. As soon as the latter are rooted, pot them up and grow on with all possible vigour. When the young plants are some 6 inches to 8 inches in height, pinch out the point of each one, and grow on the strongest shoots. When these shoots attain a length of about 6 inches, they in turn should be pinched, and the operation repeated from time to time until the last pinching has been done. Pinch plants of Mrs. H. Weeks for the last time in the first week of July, and in the case of R. Hooper Pearson, the last pinching should be carried out about the third week of the same month. The plants should be grown on to the terminal buds, and when the latter develop retain one bud only on each shoot. This treatment should give you nice blossoms, on stout, erect footstalks. Do not hose the plants until the middle of October, or even later, should the weather be mild or free from frosts. With the advent of cold weather, place the plants under cover at once, keeping them cool until the buds begin to show colour. A genial temperature when the buds begin to unfold is most desirable, as this assists in the development of the blooms, and also prevents damping. At all times see that the house is adequately ventilated.

Climbers for arches (Rustic).—Vigorous climbing or rambling plants suitable to cover rustic arches and summer-houses are: Virginian Creeper, Celastrus scandens, the stronger growing Clematises, such as Flammula, montana, and Vitalba, Honeysuckles, Lycium barbarum, Cut-leaved Grape-Vine, Wisteria sinensis, Forsythia suspensa, white Jasmine, and above all some of the more vigorous and free-flowering climbing Roses.

A good hardy Apple (J. E.).—We fear that even the hardest of Apples will not do well in the position you propose to plant—150 yards from a brickyard on one side and 300 yards from a colliery on the other, and from both you get quantities of sulphurous smoke. It is a position that may well cause to suffer the hardest of trees. If, however, you determine to plant, you may select from three varieties—Walsbam Abbey Seedling, Newton Wonder, and Bramley's Seedling, all fine free-cropping kitchen Apples and ranking as distinctly hardy. The last is, however, a very strong grower, and on standard trees worked on the Crab stock, the class of tree we presume you propose to plant, is late coming into bearing. Probably you would do well to plant some of each of the two first named.

Japanese Wineberry and Logan Berry (Massachusetts).—Unfortunately, out of nurseries, not much is yet known of the habit and strength of the Logan Berry in this country. But being a Blackberry, we have naturally assumed that it needed the space usually allotted to the ordinary strong-growing Blackberries, such as the Parsley-leaved variety, for instance, one of the very best. The Japanese Wineberry is, we know, a strong grower, needing ample room. We should certainly plant these Brambles at equal distances apart, carrying the strongest growths after they have formed away on each side and the weaker ones upright. Otherwise, the fruit of the Logan Berry is large, rather long, and black. That of the Wineberry is very red, but rather small, sharp, and not suited for dessert. Really, it is more ornamental as a climber than it is useful as a fruit producer.

Manuring Asparagus beds (Blue Lias).—Yes, you may use chemical manures for your Asparagus-beds this season, as they had a dressing of farmyard manure last year. The following is a good mixture to take of superphosphate 5 lb.; kainit 1 lb. Mix both well together and apply at the rate of 1 lb. to the square yard next month. When the heads begin to appear apply nitrate of soda, or common salt—preferably that first named—at the rate of 2j oz. to square yard, and repeat the dose on two other occasions while the plants are in full growth during the summer months. Bone-meal would

not prove very beneficial, and the other manures named are superior to sulphate of ammonia for Asparagus.

Potato plant grafted on Tomato plant (J. C.).—When a few years ago Tomato plants were grafted on Potato plants grown in pots, it was found, although in a limited way, that whilst the Tomato tops produced Tomato fruits, the Potato roots produced Potatoes. On the other hand, Potato plants grafted on to Tomato plants only caused the Potato tops to produce green swellings, like small Potatoes, at the leaf joints, but there were no Potatoes. These experiments were made more from mere curiosity than from hope of securing any beneficial results. It was found that whilst the Tomato leaves could elaborate Potato-forming sap and pass it into the Potato plant stem below the union of graft, Potato leaves, whilst elaborating Potato-forming sap, could not pass it into the Tomato plant below the union or graft. The above experiment was conducted by Messrs. Sutton and Sons, Reading.

Fowl-manure for Onions (R. W. W.).—Fowl-manure should be well mixed with root and twice its own bulk of soil, be thrown into a heap, and turned two or three times to get it all well incorporated before the whole is dressed on the soil. Even then it should be deeply dug in, a month before seeds be sown or plants put out on to the soil. You should have sown your Onion seed for transplanting early in February and thinly, so that you could have strong plants fully 7 inches to 8 inches in height, with balls of soil attached, to pot out. Maggot would not injure those, especially if at once well mixed with soil. Good stable-manure, turned and well mixed and moistened with house sewage or slops two or three times to get it half decayed and sweet, then dug in a few weeks before sowing the seed is best for all crops. Course stuff should be buried deep down under the crops.

Cleaning and manuring garden (R. M.).—Your garden, so far as the soil is concerned, is about 20 rods. The usual dressing of guano would be about 6 lb. per rod. You could apply so much as that now and well dig it in, then give a dressing of half that quantity amongst the crops in June and hoe it in. You do not state what your sack of guano weighs. Before you apply the pig-manure, if you have not done so, turn it two or three times first, so that it sweetens it. Use soot with that freely. Use it thinly and bury it well down. You cannot too thoroughly cleanse the ground of the bindweed roots before cropping, and if any should grow later, then use the hoe freely, so as to keep down growths. If Turnip seed grow hoe and kill the plants. Guano should be used very sparingly with Cucumbers. A mere sprinkle over the roots once a month to be washed in when watering is enough.

SHORT REPLIES.

C. M. Dyer.—See article "Hardy flowering plants for shady positions" in our issue of Dec. 27, 1902, p. 565, which can be had of our publisher, post free, 1/4d. —A. B. Y.—I am keeping the house too close and warm, and also watering too freely. —B. P. M.—Do not on any account use the old rotten wood, as it will only breed fungus and cause no end of trouble. Try in your pond some of the better Water Lilies, which ought to do well. —Anonymous One.—We know of no such Clematis as you speak of. —D. M.—Any bookseller in your neighbourhood could get for you whatever books you require if you tell him what you want. —M. C.—See article in our issue of Feb. 22, 1902, "How to obtain an early supply of Sweet Peas." This can be had of the publisher, post free. —D. H. S.—Dullness ought to be planted out at the end of May, and must be given a start in a well-manured position. —G. E. E.—We know of no book such as you mention. —The best book on "Vines and Vine Culture," by A. F. Barrow, price 5s. 6d., post free. —A. S.—See reply to H. Brown in our issue of Jan. 31, re "Outdoor aviary." —K. A. R.—The only thing you can do is to keep the surface freely stirred and persevere with the soot and lime-dressing. —Enquirer.—Apply to Messrs. Jas. Carter and Co., 237, 243, High Holborn, W.C. —Notice.—You had better consult our pages, where such small houses as you want are advertised. —Magdala.—It might be done if great care is taken; but on the whole we would advise you to let it alone. —Arthur P. Cook.—You cannot do better than plant the best of the Tea-scented Roses, which bloom early and also continue to start till the season. —Rector.—We know of no book that will answer your purpose. It is at any time you are in doubt we are always ready to assist to the best of our ability. —Kent.—You had best consult our advertisement columns. —Your Currant-bushes are attacked by the Currant-mite. See our issue of Jan. 24, p. 618. —South Stafford.—1, Your best plan will be to leave a chink of air on the frame. 2, You should submit your thermometers to some maker of the same, who will verify the same for you. —W. S. Taylor.—Unless your soil is very heavy clay, coal-ashes are of no value. They only in such a case help to lighten the soil, and it would be far better to give a good dressing of lime. If, on the other hand, you soil is light apply a good dressing of cow-manure. —Celery.—1, See reply to A. Croft in our issue of Jan. 31, p. 628, re "Celery running to seed." 2, The soil was out at all suitable for Savoye, which requires a good stiff, loamy soil to do well. —3, Fill it with Tea Roses, with Tufted Fantaisie planted freely over the surface. —H. V. H.—Apply to Messrs. Dickson's Limited, Chester, or Anthony Waterer, Knaphill, Woking, Surrey. —A. Langton.—"Be Keeping, book of," by W. B. Webster, post free, 1s. 2d. L. Upcott Hill, 770, Strand, London. We shall always be pleased to help you when you are in doubt. —Staffordshire Knot.—You ought to plant Spiraea Aruncus, which flowers in June; S. Umaria blooming in August, and S. filipendula and its double form which flower in September. —J. C. Bloomfield.—Do you mean the indoor or the hardy Tradescantias?

FRUIT.

THE VINERY IN WINTER.

By this date all leaves will have fallen from the Vines. This, then, is the time for pruning, which is best completed at the earliest date following the leaf-fall. Pruned early, there is time for the surface to dry and heal before the sap becomes active again in early spring. Late pruning brings a trouble in what is known as bleeding, because this once set up is most difficult to suppress. With Vines well-matured, and pruned as early as their state of rest allows, there is seldom any trouble from bleeding. As a preventive, many gardeners apply styptic or painter's knotting immediately after pruning. The pruning once completed, proceed to clean the rods by trimming off air-roots, loose bark, and dead spurs, but unless there lurk any Vine pests, such as mealy-bug, red-spider, or thrips in the bark, do not strip this off clean, as so many are disposed to do as a custom more often than necessity. When any of these insects have been in evidence during the summer—and particularly mealy-bug—then more drastic steps must be taken to clear them out. The removal of all loose bark is the first necessity, and then a dressing of an insecticide calculated to destroy it without injury to the rods. Whatever is used needs to be well and thoroughly rubbed in with a brush, being most careful that no injury is done to the dormant buds in the course of the work. It is necessary when insects have given trouble to first well clean the Vines, and then to deal with the house generally. Plants often are a means of introducing noxious insects, and where necessity compels the joint occupation by plants and Vines, some little effort should be made in winter to clear out their old haunts. Mealy-bug secretes itself in any possible crevice in the roof, plant-stages, walls, etc. Those having a hose or garden-engine, and a good force of water can do much good by applying hot or cold water with the strongest force possible. This will dislodge many. Previous to this all plants should be removed, so that they do not receive an overdose of water. They can be dealt with separately before being reintroduced. If the border be an inside one, one important detail is to remove a little of the surface soil, replacing it with fresh, preferably that obtained from decayed turf, cut and stacked in the past spring or summer. Add to this some lime rubble, burnt refuse, and a little horse-droppings, and, if possible, a coating of artificial Vine-manure. Ascertain whether the border contains sufficient moisture, and if not give a moderate soaking some time prior to the resterting of the vinery. In the case of old established Vines, and the border well occupied with roots, there is a gain in the application of liquid-manure derived from the stables, pigeries, or cow-yard. Soot is also good for Vines. Some canes, particularly young ones, are troublesome, starting irregularly in spring. This can be partially obviated by slinging

them to the roof wires and allowing the points of the rods to hang in such a manner that they almost touch the ground, or bending them round in hoop fashion, the object in every case being to check the sap from rushing to the extremities. Care is necessary in bending them that the inner bark does not get ruptured. Once the buds have burst and commenced growth tie the rods in their places, but in doing so allow ample space for swelling. W. S.

MANURING THE FRUIT GARDEN.

This does not meet with the attention it should do, for unless the soil possesses extraordinary fertility it is impossible for the trees and bushes to continue yielding heavy crops of fruit annually without assistance of some description. This is best afforded in the shape of well-rotted manure to Currants, Gooseberries, Raspberries, Apples on the Paradise and Doucin stocks, Pears, particularly those on the Quince, and to Cherries, no matter what the kind of stock may be. All of the foregoing may have a good dressing of manure to be dug in round about the roots in the case of Currants and Gooseberries, and to be spread and left on the surface in regard to Raspberries. Respecting Apples, Pears, and Cherries, it is always advisable to spread the manure to as wide a distance as the branches of the trees may extend, and then to lightly prick it in with a five-tined fork, just covering the manure and no more. Sometimes even this cannot be done owing to the great quantity of roots lying just under the surface of the soil. It would be the height of folly to disturb or injure these, therefore under such conditions it must suffice to place the manure on the surface, and to cast a little soil over it to hold it down, and to prevent birds from scratching it about. Wall Pear-trees, especially cordons, that are worked on the Quince, are always benefited by being attended to in this way yearly, and where the soil in the alley has become hard and exhausted through constant traffic it pays to remove the top 3 inches and replace with good loam and a fair percentage of wood-ashes and a little lime-rubble added to ensure porosity. If the trees need feeding, and the roots are within a few inches of the surface, this will give them the useful filp. The same kind of treatment will suit Plums, Morello and dessert Cherries, and in the last-named case do not neglect to add calcareous matter if a top-dressing of fresh compost in addition to the manure is required. Apricots and Peaches should always have a light dressing of lime-rubble spread on the alleys, even if fresh soil is not needed, for being such moisture-loving subjects during the summer months, it is requisite that water can sink in quickly, which it cannot do if the surface soil is of too heavy and close a nature. Advantage should be taken of frosty weather to get the manure wheeled on to the open ground and the alleys, and the proper quantity of compost should also be mixed in readiness for applying in the manner indicated above, as soon as the trees have received attention in the way of pruning, nailing, or tying, as the case may be. Should the weather

continue mild and there be no prospect of hard frost occurring, use planks, on which to wheel the manure and compost to where it is wanted rather than delay the work until late in the season, when there is a risk of its being done in an imperfect manner through other matters demanding attention at the same time. If lime-rubble or "scraps" cannot be obtained, bone-meal should be substituted for it, sprinkling enough of this on the surface of the ground to whiten it, and for fresh compost use a 7-inch potful to each barrow-load of soil. Wood-ashes or charred refuse is easily obtained by burning up prunings, road sweepings, vegetable refuse, etc. A. W.

DESSERT PLUMS AND GAGES AS CORDONS.

The introductory remarks are the subject of Pears as cordons appearing in a recent issue apply with equal force to dessert Plums and Gages, when grown on the same principle, as far as regards their suitability and usefulness for clothing walls to obtain greater variety where wall space is limited, also for planting to fill up blank spaces, either on walls or fences. But with regard to the question of soil, matters differ, as it does not pay to afford these cordon Plums the same rich compost that is required for Pears on the Quince, otherwise they will make nothing but rank growth, fail to bear, and disappoint the planter. In planting care must be taken to exclude animal manures, either in enriching the staple, if that is considered sufficiently good without further preparation, or in the mixing of a special compost, and to use bone-meal instead. A good compost for cordon Plums is two-thirds sound loam and the remaining third charred refuse, with a fair percentage of lime-rubble or scraps broken small added, using the latter rather liberally if the loam is heavy and retentive. The bone-meal may be used in the proportion of 1 cwt. to 1 ton of the prepared compost, and after this is added keep the mass well covered and secure from rain. It is also a good plan to prepare the compost some little time in advance, as a slight fermentation usually takes place when all the ingredients are mixed together. In such compost Plums make a much shorter-jointed growth and more medium-sized wood, consequently they come more quickly into bearing than when planted in soil containing richer constituents. Even when all this care is taken, it becomes necessary to lift and transplant some of the varieties to check their inclination to make gross growth. This lifting and the replanting of them at once in the same spot are so simple and can be done so expeditiously that it need not act as a deterrent to anyone desirous of cultivating choice Plums and Gages in this way, for, generally speaking, the one lifting suffices to throw them into a fruitful state, and they give no further trouble in this direction. One other matter before enumerating the best varieties to select from is the necessity to feed the trees when in full bearing. If this is neglected they soon become starved, make poor growth, and produce fruit of inferior quality.

The stimulant may be applied in the form of a mulching of half-rotted manure, to be placed over the roots after the fruits begin to swell, as the condition and extent of the crop can then be more easily ascertained, and the risk of affording manure to trees carrying partial or no crops at all is obviated. Where liquid-mannre is plentiful it may be used with beneficial results, and the same with the artificially-compounded "fruit" manures, if used according to the directions which usually accompany them. Rivers' Early Prolific, Stunt, Oulih's Golden Gage, Denniston's Suporb, Belgian Purple, New Early Transparent Gage, Green Gage, Bryanston Gage, Comte d'Atthem's Gage, Bonne Bouche, Anna Spath, Angelina Bardett, Purple Gage, Boulouf, Jefferson, Roine Claude de Bay, Late Transparent Gage, Coe's Golden Drop, Lato Orange, and Primate are good varieties grown as cordons. Rivers' Early Prolific is included owing to its being the earliest of Plums to ripen, and when fully so is then very sweet and agreeably flavoured. Among the other varieties named will be found the choicest and richest flavoured Plums and Gages in cultivation. G. P.

SPRING FRUIT-TREE GRAFTING.

THERE are so many comparatively worthless trees growing in gardens and orchards all over the kingdom that it is to be deplored the drastic method of renovating them by means of grafting is not widely adopted. The process is far from difficult. It means the absence of any crops on the trees operated upon for two or three years, but when the work has been well done it later means a greater improvement in the bearing and quality of fruit on the trees as compared with what has been previously seen. Literally, myriads of trees can be through grafting made into new trees. Quite old trees in a state of semi-decay are of no value for this purpose. Better grub them out and burn them, replacing Apples and Peers with Plums. The trees that are much infested with American-blight, have gnarled stems, or seem to suffer much from canker, may also be best grubbed up and burned. But there would still be left so many clean, healthy trees that only need to be worked with superior varieties to render them profitable.

The first thing to do, if not previously done, should be to at once cut from the trees of the good varieties it is proposed to use as grafting scions, stout, strong young shoots, not taken from inner stem growths, but from branches well exposed to the light. These should vary in size from that of a man's finger or less, and be at least 12 inches long. Each variety should be tied into a bundle, be labelled, then have the bottom ends fixed into the ground 6 inches deep, and in a shaded place. There they will keep fresh and quiescent until after the sap has begun to move in the trees to be grafted. Grafts should be more or less stout, according to the breadth of the stems to be worked. Large limbs or stems some 4 inches broad will require three of the stoutest grafts each. Larger ones may require four grafts, and smaller ones but two. In beheading old trees it is far wiser always to cut back near to the top of the main stem, just above where the branches fork out from the stem, rather than to leave arms some 3 feet to 4 feet long, as is sometimes done, needing so many smaller grafts being inserted. Such working never results in the production of heads of the good, robust, massive kind that is seen when the grafting is done on stont, low cut stems. Where large limbs are worked with extra stout grafts, wedge grafting—that is, opening the bark of the stem wide 4 inches down, cutting out a small wedge-shaped piece of wood within the bark, making the base of the graft, which may be 7 inches long, wedge-shaped also, just to fit the cut, driving it into the position firmly, drawing the bark over it, and when the other grafts are inserted tying them

securely into place by means of lengths of raffia, or some other suitable material. Smaller grafts need only to have their bottom ends cut sloping or wedge-shaped to a length of from 4 inches to 5 inches, then the bark of the stock or limb to be grafted slit down so far with a sharp knife, the bark opened or removed from the wood just there by forcing into it a piece of pointed wood, the graft forced firmly into the place, then tied round securely. The old practice of placing some clay, which has been just mixed with one-third its bulk of beaten horse-droppings, mixed and kneaded over and about the graft to exclude air and rain is a good one, and should be done neatly. If in finishing off the claying the worker's hands be dipped once or twice into water, the smoothing off is very complete. That coating can remain until the swelling of the graft later breaks it up; then also the ties should be cut. But to prevent strong winds from blowing the grafts out, a stout stick should be tied to the main stem below the grafts, and to that the young shoots from the grafts be tied, as in that way injury is avoided. Grafting wax painted on whilst hot over the ties and wounds to exclude air and wet is also an effective protection. Grafting is, as a rule, done about the middle of April. In any case, the work should be done just as leaf-buds begin to swell, as then the sap is becoming active. Tree-heads to be finally removed may be hard cut back at once, leaving lengths of from 2 feet to 3 feet stems to be cut off clean without breaking the bark, just when the operation of grafting is to be performed. A. D.

Old fruit-trees cut down and ready for re-grafting.

NOTES AND REPLIES.

Peach-buds dropping.—I have a Peach-tree under my care. I am not quite certain as to variety—it may be Hale's Early. The fruit ripens in August. The tree, growing on a south wall, is healthy, makes very nice bearing wood and full of bloom-buds, which fall in the spring. I have followed the instructions given in GARDENING as to pruning, lime, manure, etc., etc. I have covered with netting. The bees worked the blossoms. I also used the rabbit-tail, and had eight Peaches for my trouble.—WORTHING.

[It is very probable that your Peach is one of the American varieties, which are very subject to bud dropping; or it may be that the border was too dry in the autumn, and the requisite moisture for the proper nourishment of the buds not being forthcoming in the spring the buds fail to properly develop, dropping off in scores when the trees again become active.]

Grape falling.—I should be glad if you would advise me as to the treatment of Vines? I have two Grape-Vines in a greenhouse about 18 feet square. They are planted in a bed outside about 12 feet by 9 feet, enclosed by a wall, the surface of the bed being about 2½ feet above the surrounding ground. The Vines are about 24 years old. They have never done well, and they have done worse still the last few years. The Grapes appear to be doing well until they begin to ripen, when a large portion of them shank or remain red and sour. The roof is shaded in very hot weather, and there are hot-water pipes which are used in severe weather only. I have sometimes thought the trouble was caused by dryness at the roots, but that could not have been the cause last summer, when the Grapes suffered more than usual. I notice that you sometimes recommend replanting. Would you advise it in this case, and if so, when?—EAST ANGLIAN.

[The fact of your Grapes doing well until the colouring stage is reached shows that it is a bad case of shanking, caused either through the roots having got out of control by descend-

ing into the cold subsoil, or in consequence of the soil in the border being sour and inert; most likely the former cause, according to your note. The best remedy for this is to lift the roots of the Vines and lay them out afresh in new, sweet compost, after clearing out all the old material and concreting the base of the border to prevent a recurrence of the evil. Seeing that lifting cannot be done until autumn, your best course would be to hasten the ripening of the Grapes this season, so that they may be cleared off the Vines not later than mid-September, and then lift the roots at once. As full directions for carrying out this operation would take up considerable space in this reply, an article dealing specially on this subject will appear in the columns of GARDENING shortly, wherein you will find very necessary detail treated upon. On the other hand, should you deem the Vines not worth the trouble of lifting, then we advise you to root them out and replant, and the present is an excellent time to do it. In this case no half-measures will suffice, and we strongly advise you to clear out the whole of the old border, and concrete the bottom if you find that has not been done. The total depth of the border, including the drainage, need not exceed 3 feet, so that you may fill up the bottom somewhat before concreting if the excavation when cleared out exceeds that depth. Provide an outlet at one corner—the lowest—to carry off water, and connect it with the nearest drain. The concrete floor should have a fall of 6 inches from back to front, and a drain should be laid along the front to conduct the water to the outlet already mentioned. This would not be required at present, as the border, which is best made up in sections, need not be wider than 3 feet the first year. The following year another strip or section may be added, and repeat this each year until the boundary wall is reached. On the concrete place clean drainage, 9 inches deep, consisting of broken bricks in two sizes, the largest or whole bats at the bottom, and the smaller, of similar size to road metal, on the top, and about 4 feet in width. On the place curves, Grass side downwards, or a thin layer of oaten straw, to prevent the compost from getting amongst and choking the drainage. You will not require a great quantity of compost to start with. The basis of this should be sand, calcareous loam, or, in other words, virgin loam, which is the top 3 inches cut from an old sheep-pasture or deer park. Put on one side sufficient whole turves for covering the drainage with, also to build up a wall to form the front of the border with, and to hold the body of compost in place. Then chop up the remainder, not too small, and to each cartload add ½ cwt. of bone-meal, ½ cwt. of ½-inch bones, one barrowload of wood-ashes, and the same of lime-rubble. Mix well together, and make up the border while the ingredients are dry, spreading the compost evenly as it is wheeled in, and consolidate it by treading, for the border can hardly be made too firm. Allow a week or ten days to elapse after the border is finished, and then plant the Vines, which should be what are termed planting canes.]

Apple-trees producing small fruit.—I should be extremely grateful if you would give me some advice as regards my Apple-trees. They are Blenheim Orange, King of Spain, Wellington, and Duchess's Favorite, and I few I do not know the name of. They bear a large quantity, as a rule, every year, but they are mostly small fruit. The trees are mostly 10 to 20 years old they tell me. The soil is clay. I read your answer to "H. H." in issue of December 13, and to "M. J." on December 27. Would this treatment be advisable? It would be a great expense to root-prune, as I only have a youth of 16 in the garden, who would not be able to tackle this by himself, as there are about 30 trees.—E. V. H.

[Your Apple-trees bearing such a quantity of fruit proves to us that they do not require root-pruning, and we think that the cause of the fruits being small arises either from the trees standing in need of a general thinning of the heads (branch pruning), or that they may have become impoverished through such constant fruit bearing and need feeding at the roots. If, then, the heads of the trees are crowded with wood or branches through which sunlight and air cannot penetrate, or but imperfectly, to the inner parts, the way to proceed is as follows: With a sharp saw begin by first taking out the dead and all branches and any portions of wood that cross and rub against each other, and which tend to block up

the centre of the trees. After this the remainder of the branches should be judiciously thinned, so that they stand clear of each other, retaining those which grow in an outward direction in preference to any that may be inclined to grow towards the centre, and when finished the heads should be just thin enough that both light and air can have free play in the interior of the trees—two most important factors in fruit culture. It is just possible that some of the branches retained may need shortening back somewhat to preserve an even balance of growth, and if this is necessary, cut to where a spur or young growth emanates from the branch. If the trees and varieties are mossy or covered with Lichen, spray them with alkali solution, or dust them well with equal quantities of freshly-slaked lime and soot when damp after rain, choosing a still day for applying it. On the other hand, should the pruning have had proper attention, and a root stimulant only be required, set about it in the following manner: First remove the soil round about the trees (to as far as the branches extend) carefully with a fork, until a good few roots are met with. Then apply a dressing of

and raised under the same conditions as advised for Cucumbers. Rather more loam may be used for the seed pots, and nothing else when shifting the seedlings into larger sized pots. If the pot system of growing the earliest crop finds favour, get the pots prepared in due course, and, again, on the other hand, if the planting-out system is preferred, get the house or pit cleaned and the bed made up, if pits overlying hot-water pipes to afford bottom-heat are not present, using Oak or Beech-leaves for the purpose. Such a bed is valuable at this season, and can be utilised for many purposes until the Melons are ready for planting out. Like Cucumbers, most growers have their pot varieties, but if it can be procured true, there is nothing to surpass Devonham Early for first crop, as it is not only a good cropper, but it arrives at maturity more quickly than any other Melon I am acquainted with.—A. W.

APPLE MERE DE MENAGE.

This is a large flatish fruit, taking on a rich dark crimson colour most seasons. It makes a very telling dish on the exhibition table as a

Apple Mere de Menage

well-rotted manure, 4 inches thick, placing this right over the roots, tread it firmly, and then return the soil. A better method still, if you have the material at command, is to make a compost consisting of one-half rotted manure, and the other half fibrous loam and charred refuse, such as the residue left after burning prunings, sweepings, etc., and as this latter contains a certain amount of potash, is valuable manure for Apples. Mix this together, and apply a dressing of it 6 inches thick over the roots, and cover this with as much of the staple as is required to bring all up to the proper level. If the trees are growing on Grass, place the top spit Grass side downwards either on the manure or compost when filling in, as the roots will in time take possession of and appreciate this when they push upwards. Much may also be done by applying chemical manure on the surface during the growing season, but the above remedies are by far the best if the trees are, as we imagine them to be, full of wood and stunted, or incapable of making little or no new growth, and we strongly advise you to proceed with the work on the lines indicated as early as possible.]

cooking variety. We have it now (first week in February) in fine condition, though this has not been an ideal season for keeping fruit. The tree finishes up good fruit on the Paradise, but is inclined to spread rather much, so that most of our trees are grown in the bush style. It does well as a standard, and will be found to crop best on old trees. If grafted on the Pear-stock or regrafted on healthy young orchard trees, it soon forms a remunerative tree, but should it grow too rampant, it is best to transplant each season until fruit-bearing wood is formed, when root-pruning every few years will keep the tree fruitful.

EAST DEVON.

Wyken or Warwickshire Pippin.—

An old favourite Apple in the midlands, fruiting well as a standard, and about right from Christmas onwards, the flesh being very tender and easy of digestion. It crops every other year with me, and is much in request for the table. The fruit is not particularly large but good, of dessert size, and has a yellowish-green appearance. Espalier or bush trees crop well under any treatment, and no fruit could be more regretted adding this variety to a however small a collection.—EAST DEVON.

TREES AND SHRUBS.

NOTES AND REPLIES.

The Sweet Pepper Bush (*Clethra alnifolia*).—In our issue of Jan. 31, the illustration of the above was prepared from a photograph sent by Miss Sophie M. Wallace, South Lake, Co. Donegal, and not as there stated.

Forcing Lilac and Guelder Rose.—Will you kindly tell me whether Lilac and Guelder Rose can be forced in the same way as Deutzia, or is any special treatment required? I have been told that Lilac must be put into a warm, dark cellar until the flower-buds can be seen, otherwise I shall get all leaf and no bloom. My plants of Lilac were taken up about a month ago and potted, and are still standing on a bed of ashes in the open ground.—IN THE DARK.

[Both Lilac and Guelder Rose can be forced in the same way as Deutzia gracilis—that is to say, no special treatment is required. Lilac is often forced in the dark, but that is when it is needed to be in bloom very early. At this season there is no difficulty whatever in the matter, provided, of course, the plants are well set with bloom buds. You may take the plants that are potted under glass at once, but a temperature of 45 degs. to 50 degs. will be sufficient for a start.]

Cedrus Decidua unhealthy.—I enclose photo of trunk of Cedrus Decidua, which is losing a great quantity of sap from wounds about 10 feet from the ground. My employer is anxious not to lose the tree. The sap as it flows down seems to be in a state of fermentation. I have not been here long, but I am told the tree has been like it about twelve months. I should be greatly obliged if you could make any suggestion as to cause and cure?—DROBARA.

[Your Doodar seems to be in a bad state, and we question if there is any effectual remedy. The better way will be to trim off any decaying matter from the wounds with a sharp knife, and thoroughly dress the place with gas-tar. This should be kept to the wound only, and not carried over the healthy bark. Two or three applications may check the discharge. The cause of the trouble is difficult to say. Perhaps the subsoil is in a stagnant condition, in which case a slight accident to the bark of the trunk has gone from bad to worse.]

The Golden Tree-Ivy.—There is a bush Ivy, quite golden, which, by grafting in a certain way, produces low-growing plants a few inches high. I shall be much obliged if you can tell me how to proceed—what roots to get and what grafts? I am told it takes two years to come to perfection.—O. K. E.

[There is a form of the Tree-Ivy with pretty golden foliage known as *Hedera arborescens foliis aureis*. It is usually propagated by grafting, but not because it exercises a dwarfing influence on the plant. The reason is, the Tree-Ivy in its various forms does not strike readily from cuttings; hence in nurseries, where the object is to obtain saleable plants in as short a time as possible, they are frequently grafted. Still, cuttings can be struck, though they take a long time, and plants obtained in this way are preferable to the grafted ones. For grafting, young healthy plants of the common Ivy are chosen as stocks. These are cut down to a height of 5 inches to 6 inches, and then grafted as near the root as possible. Side grafting is usually employed, and when the operation is complete, and the scion tied securely in position, they are potted at such a depth that the point of union is fully covered with the soil. After this they are placed in a case frame and kept shaded till the union is complete. From May to August is a good time for grafting the Golden-leaved Ivy.]

Trees and shrubs for gardens

(J. E. Keenan).—As the autumnal tints of the Sugar Maple are more or less yellow, they cannot be considered likely to clash with those of the Scarlet Oak. When trees have been planted some years they will need but very little attention. Certainly the soil about the roots should not be dug, but in poor soils, especially, the trees are benefited by a mulch of decayed leaves or something in that way. In the case of young trees they should certainly be kept clear of Lichens, but in the case of an old specimen they add to its picturesque appearance. The number of trees suitable for fairly large gardens is, exclusive of Conifers, very considerable, a few very desirable ones being as follows: *Acer dasycarpum* (Silver Maple); *Acer pennsylvanicum* (Moose-wood), remarkable for its striped bark; *Acer platanoides* (Norway Maple); *Acer rubrum* (Scarlet-flowered Maple); *Acer saccharinum* (Sugar Maple); *Fraxinus pennsylvanicum* (Horse Chestnut); *Esculus rubicunda* (Scarlet-flowered

Horse Chestnut); *Ailanthus glandulosa* (Tree of Heaven), long pinnate leaves, keeps green throughout hot summers; *Amelanchier canadensis* (Snowy Mespilus), a low tree, but a beautiful flowering one; *Amygdalus* (Almond), charming flowers in early spring; *Betula* (Birch) in its different forms; *Catalpa bignonioides*, flowers in July; *Cerasus* (Cherry) in different forms; *Crataegus* (Thorn), a great number of beautiful kinds; *Fagus* (Beech); *Fraxinus* (Ash); *Lahurnum*; *Liquidambar styraciflua*, remarkable for its rich autumn tints; *Liriodendron tulipiferum* (Tulip Tree); *Magnolias* of sorts; *Morus nigra* (Mulberry); *Fraxinus Ornus* (Flowering Ash); *Platanus* (Plane); *Pyrus* of sorts; *Quercus* (Oak); *Robinia Pseud-Acacia* and its varieties, retain the brightness of their leafage throughout the hottest summers; *Tilia* (Lime); and *Ulmus* (the Elm). Of evergreen trees, exclusive of Conifers, the best are: *Arbutus Unedo*, and its variety *Crooni* with scarlet flowers; *Ilex* (Holly) in various forms; *Magnolia grandiflora*, and *Quercus Ilex* (Evergreen Oak). All of the above are beautiful and not particular in their requirements, but if you had stated a definite number we should have been able to have helped you in a more satisfactory manner. However, should you require any point further elucidated we shall be pleased to give our attention to it.

PLANTS AND FLOWERS.

ROOM AND WINDOW.

COCOS WEDDELIANA FOR ROOMS.

AMONG the many Palms which are highly ornamental when young is this *Cocos*, and for the embellishment of the warm-house it is very popular. A general idea prevails that because it is a native of Brazil stove culture is absolutely necessary for its well-doing. Such is, however, by no means the case, as it is a thoroughly good room plant, and one that flourishes with me in a room where a fire is only occasionally lighted. Of course, the precaution is taken of shifting the plant to the centre of the room during frosty weather. My plant has stood for the last three years under such conditions, and I am acquainted with one that has been for the last ten years so treated, and now forms a beautiful specimen. Very important items concerning Palms kept in a dwelling-house are, firstly, to see that the leaves are frequently sponged clean, and, secondly, to take care in watering, for the soil should never be allowed to get very dry, and at the same time an excess of moisture is just as injurious. Above all, do not allow water to remain in the ornamental pot or saucer in which the plant stands. The mortality among Palms kept indoors is very great, and this is, apart from the irregular treatment they often meet with, largely caused by the conditions under which their early life has been passed, as in nurseries, where they are grown in quantity, the object is to get saleable specimens in as short a time as possible, hence they are pushed on in a warm, moist atmosphere, and consequently suffer greatly when they are removed therefrom to less favourable conditions. If these Palms were grown cooler from the first, or gradually inured to the altered conditions of things, the mortality among them would be far less. W. T.

Fine foliaged plants in rooms.—All fine foliaged plants that are kept in dwelling rooms benefit by a little extra attention at this, the duller part of the year, especially in rooms where fires and gas are much used. It is surprising what an amount of dust and soot will accumulate on the leaves of Palms, Aralias, India-rubber plants, Aspidistras, and similar subjects having a broad surface, and to keep such plants in a normal condition is often a puzzle to those who have little or no glass accommodation. A deal may be done, however, by simply using soap and water and a sponge, and then washing off with clear water. A change of room, too, perhaps, where the little sunlight we have reaches the plants earlier, often makes a wonderful difference, not omitting, of course, to open the window for a short time each midday.

ROSES.

Climbing Rosea on old trees.—I have some old Austrian Pines which I wish to utilise as props for Rosea. I find that when their branches are injured they make no fresh growth. Would the Ramblers succeed in such a position, or would the roots of the trees rot them? If so, can I do anything now to kill the roots, and still keep the trees firmly fixed? As my garden is absolutely unsheltered, firm staking is of the utmost importance. The garden is open to N., W., and S., about 200 feet above the sea, so the exposure is great, but in summer *Tropaeolum speciosum* blooms splendidly on the N. side of house, facing the sea.—LONDON.

[What magnificent objects Roses are on old trees—that is, when proper sorts are chosen and a little trouble is taken in planting them, as then they grow freely and send their long shoots up and over every branch where they can find support. Any tree going into decay, or that is half dead or shabby, will do, as all that is wanted is a support for the Roses. The way to give the Roses a good start is to well break up the ground where they are to be planted and to work in a heavy dressing of rotten manure. If, however, the soil is poor and bad, it is advisable to dig out a largo hole and put in some fresh soil, as much depends on the way the Roses are treated at first and the attention they get at that time. Any of the hardy climbers are the best to use, and they look well when the colours are blended, such as Cheshunt Hybrid and Aimée Vibert, while Clematises and pale coloured Roses make a fine contrast.]

Cocoa-nut-fibre refuse as a protection.—I have not used the long fibre alluded to by your correspondent in GARDENING, p. 611, at least, not as a protecting material, but having had occasion to employ it this season for packing, I can well believe this fibre would be an excellent substitute for Bracken Fern. A hundredweight of it would go a long way, and it could not fail to be very useful, especially for standard Tea Roses. I never hesitate, however, to recommend dry straw to all who find a difficulty in obtaining Bracken. Take a truss of straw and cut it in half with a hay-knife, then stand some of it among the branches. This is better than slaking on the straw with a fork. If earth is well drawn up to the base of the plants previous to applying the straw, bush Tea Roses will pass through any average winter unharmed. Avoid the use of any material when in a damp condition. The growths of Tea Roses suffer much injury from this cause alone. It would be better merely to earth up the plants. Evergreen boughs stuck in among the branches of the Roses are also excellent material, common Yew, Spruce, Fir, or Arbor-vitæ being the best.—ROSA.

Tea Roses in cool greenhouse.—Some Tea Roses potted last year in 5-inch pots were altered blooming placed outside to ripen. When the frost came a fortnight ago I placed them in a cool greenhouse with a lamp to keep out the frost, which has not been used since the frost departed. I find the Roses are pushing on very quickly, and a *L'Idéal* and *Catherine Mermet* are getting into leaf. Must I place them outside again to keep them backward, or must I keep them as cool as possible inside, and prune them rather earlier than usual? I suppose in the natural order of things they should be pruned in March? The temperature for some days during the frost was from 24 deg. to 26 deg.; to-day the thermometer in the shade outside shows 31 deg. Having been potted last year, probably they will not require repotting this year.—BIRKDALE.

[Your best plan will be to prune the plants at once. Cut them back to plump, dormant eyes, taking care to leave the ripened growths of *L'Idéal* as long as possible, and afterwards, by twining them around three sticks stuck in the pot, you will obtain much more blossom than if grown erect. As the plants are rather forward, paint over the cut ends of the growths with some painter's knotting to prevent loss of sap, or "bleeding," as it is technically termed. It is much better to prune now than defer it until March; but you must endeavour to keep out frost when the new growths are advancing. If you keep the temperature low now the plants will break into new growth very steadily, and be better able to stand a low temperature next month. The plants will not require repotting again until midsummer, and even then it may be advisable to defer the work until another year. This will depend upon the condition of the roots. If the pots are full of roots, then repotting is beneficial, but much harm is often done to Roses by repotting too frequently, or at unsuitable periods of the year.]

OUTDOOR PLANTS.

EVERLASTING FLOWERS.

A GOOD supply of the different kinds of Everlasting-flowers cannot fail to be appreciated, especially at this season, and by those who have not the means of obtaining fresh ones. Nicely made-up bouquets of variously-coloured Everlastings, with a few dried Grasses, etc., are very effective, and do duty throughout the whole of the winter, or with care sometimes longer still. The

HELICHRYSUMS are still among the most useful and popular of all the different descriptions of Everlastings, and fortunately the plants thrive nearly, if not quite, as well in a smoky back-yard as under the most favourable surroundings. The plants are hardy annuals, and easily raised from seed; but as they require a rather long season of growth, it is desirable to sow the seeds as early in the year as possible, so that a little artificial heat in which to raise the plants is very desirable. Sow, then, in February or March, rather later in town than in country places, using any light, rich soil, and placing the pan or box in any moderately warm frame or greenhouse. Prick off the plants singly when fit, and when a certain amount of growth has been made harden them off, and finally plant out at the end of April or May in good, rich soil, at 18 inches or 2 feet apart. Such early raised plants will make fine bushes before the end of the summer, and produce quantities of the white, golden, bronze, pink, scarlet, or crimson blossoms. These must be gathered—with good long stalks—when little (if any) more than half expanded, and always on a dry and sunny day. Tie them up in small bunches, which hang heads downward in a sunny window or other dry place, until the stalks become stiff as wire, when the flowers may be hunched. If left on the plant until fully expanded, the flowers are overblown when dry, as they open a good deal in the drying. It is a good plan to gather some in various stages, but none more than half expanded. The seed is sometimes sown in autumn in the open air, and on light warm soil this answers well; but it does not answer for town gardeners, where the ordeal of winter is often too much for the plants. Those who cannot grow *Helicrysums* in any other way will find they make very nice pot-plants, one plant in each 3-inch or 6-inch pot. The

RUOHANTHES are very graceful, the pink and white forms being chiefly grown. The plants are, however, more slender and delicate than the last, and need more care as well as to be planted closer. Sow in March or April, pricking off and planting out 5 inches apart when strong enough. These are largely grown in pots for the London markets, a dozen to twenty plants being placed in each 5-inch pot. ACROCLINIUMS, white and rose, are very pretty; they are half-hardy annuals, as easily grown as *Asters*, and there is also a fine double-flowered form. Like the *Helicrysums*, the flowers must be gathered before they expand fully.

NERANTHEM ANNUM produces flowers of a bright violet-purple colour, and will be found very useful. It is a hardy annual, and may be treated the same as the *Helicrysum*. There is also a form with double white flowers. The old-fashioned

HONESTY (*Lunaria biennis*) is another very useful plant in this connection, though in this case it is not the flowers, but the silvery-white inner membrane of the large oval seed-pod that is the lasting and useful portion of the plant. This is a biennial, and must be sown in April to flower and "pod" the following summer. It is best to sow where the plants can remain, as they do not relish being disturbed. As soon as the outer skins of the seed-pods become loose, cut the spikes bodily and remove both them and the seeds carefully; if left too long they become discoloured by wet. When cut the spikes should be put in a dry cupboard, safe from dust, until wanted for room decoration, when they can be arranged very effectively with dried Grasses, etc.

Bush Sweet Peas.—During the last summer this type of Sweet Pea was found in a few gardens. I had six kinds sent me to try. These I sowed in 7-inch pots in February,

bringing them forward in cold pit. When strong enough, they were planted out in deeply-worked soil without disturbing the roots. On the approach of summer they were mulched and spray stakes put to them when growth had advanced sufficiently. I thought these would have bloomed somewhat close to the ground. But this was not the case. They grew from 3 feet to 4 feet high and bloomed freely to the very tips, but the colours were poor compared to those of the tall-growing forms. I would not grow them if I had accommodation for the tall ones, and I doubt if these or the Cupid type will ever be grown to any extent, the size of bloom being so much against them.—J. CROOK.

GYNERIUM ARGENTEUM (PAMPAS GRASS).

This noble Grass, 4 feet to 14 feet high, according to soil or district, is most precious for our

and watered copiously in hot, dry weather. Of this there are several forms, including

G. ARGENTEUM ACUTI-LINEATUM, in which the habit is generally not so strong, the leaves narrower than in the type, and arching so that the tips reach the ground, and

G. ARGENTEUM RENDATLERI, in which the plumes are more one-sided than in the original form. Its chief value lies in the great freedom of flowering, as also in its robust growth.

G. JUBATUM as yet has not been tried much, except in favoured spots. The leaves resemble those of *G. argenteum*, but are of a deeper green, and droop elegantly at the extremities. From the centre of the tuft, and exceeding it by 2 feet or 3 feet, arise numerous stems, each bearing an immense loose panicle of long filamentous silvery flowers, of a rosy tint with silvery sheen. It is a native of Ecuador, and comes earlier into bloom than *G. argenteum*.

The sexes are borne on separate plants in all the species, and the plumes of male flowers are

POISONOUS PLANTS.

SOME of the most dangerous plants that are to be found in English hedgerows and fields possess properties that make them of great value medicinally. The Deadly Nightshade (*Atropa Belladonna*), the Aconite or Monkshood (*Aconitum Napellus*), the Meadow Saffron (*Colchicum autumnale*), the common spotted Hemlock (*Conium maculatum*) are all powerful for good in skilful hands, and equally powerful for evil when consumed without knowledge of their character. Belladonna is obtained from the Deadly Nightshade; aconite from the Monkshood; colchicum wine is made from the seed and root of the Meadow Saffron; Succas conii is prepared from the juice of the Hemlock; digitalis is obtained from the leaves of the Foxglove (*Digitalis purpurea*).

THE DEADLY NIGHTSHADE grows wild in most parts of England. It is usually found in the hedges of shady lanes and planta-

The Pampas Grass (*Gynerium argenteum*). From a photograph sent by Sir G. Errington, Bt., Ramsfort Park, Gorey, Co. Wexford.

gardens, but in many districts suffers from severe winters, and we seldom see such a fine group of it as that we figure to-day. There is reason to believe that some varieties are better in habit than others and flower earlier. In such cases it would be better to patiently divide them than to trust to seedlings. It should be planted far more extensively than at present, and given very deep and good soil. The soils of many gardens are insufficient to give it the highest vigour, and no plant better repays a thorough preparation, especially since one preparation suffices for many years. If convenient, give it a somewhat sheltered position, so as to prevent as much as possible that ceaseless searing away of the foliage which occurs wherever it is much exposed to the wind; and because, when beaked by shrubs, its bright silvery plumes are less liable to be injured. It should be planted about the beginning of April, mulched with rotten manure,

neither so handsome nor so durable as the plumes of female flowers.

Sir George Errington, to whom we are indebted for the photograph from which our illustration is prepared, has kindly sent us the following notes as to the plant figured:—

"The illustration is from a photograph, dated Christmas, 1892, of a group of Pampas Grass at Ramsfort, Gorey, Ireland. The climate and soil are so suitable that the Pampas Grass grows over 20 feet high, and in a calm winter, like this one, lasts well into February without being much dishevelled. There are three or four varieties here, but the common one I think most effective. The New Zealand Flax (*Phormium*) also grows here to a great size, and constantly flowers. There is no peat, but there is also entire absence of lime, so that Rhododendrons thrive wonderfully, and, I might say, in a sort of cold white clay."

tions and about ruins. The flowers are bell shaped. In colour they are purple or lilac. The berries are a rich deep black and very sweet. The odour of the whole plant is nauseous and oppressive, and in this way it gives warning of its venomous nature. The Deadly Nightshade ought to be uprooted and removed from all places that stock have access to, otherwise, sooner or later, a serious loss may be sustained.

THE ACONITE is also called Monk's Hood and Wolf's-bane. The flowers are deep blue in colour. Monk's Hood can easily be recognised because one sepal of the calyx is in the form of a hood. It is not generally believed to be a native plant. It is found growing wild in some parts of England, but is more frequently seen in cottage gardens and in shrubberies. Lindley said that the Aconite yields to no plant in the virulent poison of its roots. All parts of the plant are poisonous. Many people

have been poisoned by carelessly eating the root of the Aconite in mistake for Horse-radish; in colour and in shape the roots of these two plants differ considerably. The power that Aconite possesses of controlling inflammation and cutting short the accompanying fever is said to be marvellous: it is of marked service in erysipelas. Poisonous plants are frequently grown in gardens for the sake of their flowers. If the garden happens to be situated near a stream or river, it is the dangerous practice of some people to throw plants of this kind into the water. They are thus carried to fields through which the stream flows, and occasionally take root in the banks, and thus become a source of danger to stock that may easily be overlooked.

MEADOW SAFFRON is a native of England, and is found growing in pastures and meadows in many parts of the country. I have seen large beds of it in pastures adjoining the Severn, and also on an estate near Ludlow. The son of the owner of this estate pointed out a field where a number of cattle were poisoned and died in consequence of eating the Meadow Saffron that grew there. A few years ago I was warned by a farmer not to rent a pasture near Shrewsbury that was advertised to be let, the reason given being that it was "unlucky land." A dealer in cows, he said, who occupied the pasture for many years lost heavily by the tenancy, many newly-purchased cows having died suddenly. The cause of this mortality, though it was attributed simply to bad luck, is doubtless explained by the fact that the pasture contained a bed of Meadow Saffron. The Meadow Saffron is rather like the Crocus in appearance; the flowers are purple in colour, and do not appear till the autumn. The leaves appear in spring. The plant is dangerous for cattle, both when it springs out of the ground and when it is in bloom. Drying does not destroy its poisonous property. Hay containing Meadow Saffron is said to "purge horses and all stock that eat it." Colchicum wine, which is made from the root and seed of the Meadow Saffron, is said to be the most valuable remedy we possess for the treatment of gout. From the leaves of the

FOXGLOVE the well-known drug digitalis is obtained. Digitalis is useful both in heart cases and in dropsy. Dr. English, of Sleight, recommends Foxglove leaves, after being steeped in boiling water, as an external application in the case of heart pain. I can testify that the leaves used in this way are efficacious. The

COMMON SPOTTED HEMLOCK is a biennial, and varies from 3 feet to 6 feet in height, according to the soil in which it grows. The Hemlock is umbelliferous, the flower-stalks growing like the framework of an open umbrella. There are purple blotches or spots on the stem, which is erect, hollow, and perfectly smooth. The root leaves are large and deeply cut. The flowers are white, and, on being bruised, give out an odour like mice. Hemlock was the state poison of ancient Athens. The death of Socrates was caused by poison obtained from this plant. Cancerous ulcers, according to a medical authority, are often relieved by a preparation obtained from the juice. Although Hemlock is very injurious to stock when consumed green, it loses much of its poisonous properties when dried, as in hay.

FOOL'S PARSLEY is described by my brother, Mr. John Turnbull, as follows—

"This is also an umbelliferous plant. It has three little bristle-shaped leaves hanging down from the top of each branch of the umbel just under the flowers, giving a bearded look. It cannot be mistaken when once seen. A most dangerous plant I found it here (Great Linford), infesting our Horseradish-bed. This plant has caused many accidents, its leaves having been mistaken for Parsley. The flowers of the Parsley are yellow, and the stem of the Parsley, when bruised, is free from the disagreeable odour that characterises the Fool's Parsley. The root contains a virulent poison."

Yew (*Taxus baccata*) is a dangerously poisonous tree. When plants have an ill odour or flavour, animals naturally avoid eating the foliage, but the Yew gives no warning of this kind. Every part of the tree is poisonous. The leaves when old are more dangerous than

when they first appear. The Rev. Professor G. Henslow, in his interesting work on "Poisonous Plants in Field and Garden" (published in 1901 by the Society for Promoting Christian Knowledge), records the case of three horses that were to have been sold at a country fair. On their way the horses were tethered to the railings of a churchyard, over which some Yew boughs were hanging. The horses ate the leaves, and all three died. Notwithstanding the well-known evil reputation that the Yew has in this respect, the clippings of Yew-hedges are frequently deposited on rubbish-heaps situated where stock have access to them. A considerable number of cattle on a Leicestershire farm were poisoned as the result of this thoughtless practice. There is one other plant,

THE LABURNUM, a tree found in gardens all over the kingdom, that I think is desirable to call special attention to, as so many children have been made seriously ill by eating the green pods and seeds.

There are many other poisonous plants besides those I have named, amongst others: Black Nightshade, Woolly Nightshade, Hemlock, Water Dropwort, great Water Parsnip, Water Hemlock or Cowbane, Honbane, Spearwort, Fetid Hellebore, Columbine, Lesser Stitchwort, Sheep's Sorrel, and Black Bryony. Having regard to the large number of men, women, and children, and of farm animals that have been poisoned in England by eating noxious roots and berries, the importance of imparting accurate knowledge on this subject to country children cannot be doubted.

ROBERT E. TURNBULL, in *The Field*.

SWEET PEAS.

THESE are deservedly popular, and their popularity is likely to extend in consequence of the great improvements that have been made in a comparatively short period. There are now in existence many varieties so beautiful and striking that they have been named, but this has been carried a little too far, for there is no denying the fact that shades barely perceptible characterise varieties totally different in name. There are a great many that are too much alike. There is always a danger of this happening. Though we are glad to accept anything new and distinct, and welcome it by a name under which we can henceforth be sure of obtaining it, if naming is pursued too freely confusion results. It will be so among Sweet Peas; in fact, it is so now, for a great many have no opportunities to try and find out the distinct ones, and thus they are not known to many. Sweet Peas are so easily grown that they may truly be called everybody's flower. We ought to find a place for them somewhere, be the garden ever so small, and if any unsightly object is to be screened from view for the summer, what is there better than these? Next to their exceeding beauty when growing, we must take into account

THEIR VALUE AND USEFULNESS for cutting. They may be cut in unlimited quantities, and it is wise to do so. If the flowers are not cut they fade and produce seed, and, unless seed-pods are removed, the flowering season is a short one. When I cut them I do not merely cut the flower-spike, but the shoot as well. In the first place, it is not possible to arrange Sweet Peas prettily and informally unless they are cut in this way. No foliage suits them so well as their own. Although at first it appears to be a sacrifice—a ruthless destruction of future blossoms—as a matter of fact, the very practice ensures continuity of bloom. The shoot that is thus stopped breaks out into many laterals, and these are quickly in flower. It is only by hard cutting that we find out what an amazing quantity of bloom a small row of Sweet Peas will produce, and the results are even better than come from merely picking off the seed-pods, as in this case the climbing shoots keep lengthening without branching, and unless provided with very tall sticks they reach the top and fall over. By persistent cutting the plants are never out of reach, and though we strip the row of flowers to-day, before a week is past they are abundant again. Those that have many friends to whom they like to give flowers can be generous indeed, if they grow Sweet Peas. Not only do they look well and last when cut, but they are well

and, above all, their refreshing sweetness is universally appreciated, as there is nothing faint, heavy, or oppressive in their scent. Their successful culture is summed up in a few words. First, prepare the ground thoroughly by digging and enriching it with manure. Sow early in February if weather permits, but in any case in March. Do not sow too thickly, as the plants branch freely. Birds and slugs must be watched for; dusting the plants with soot when damp with dew or rain makes the shoots distasteful to either class of depredators, and, in addition, promotes healthy growth. Stakes should be given before the plants are too tall, and then all that remains is to keep them from seeding, and they are a source of pleasure and enjoyment for five months at least. H.

TUFTED PANSIES.

EARLY SPRING PROPAGATION.

FEW persons are aware that Tufted Pansies may be propagated with ease from cuttings in late winter and early spring. Where stock is scarce in the autumn it is a good plan to leave the old stools undisturbed until the earliest days of February. The old clumps have recovered from the spell of severe weather recently experienced, and are now breaking freely into growth. Cold-frames are ready for their reception, and nice light and gritty soil has been prepared into which to dibble the cuttings. I prefer a layer of this compost on soil which has been deeply dug and subsequently levelled down. A layer of this light and gritty soil to a depth of quite 4 inches is necessary. The soil should be made fairly firm. Cold-frames that are shallow are preferable to all others for this work, the ordinary deep frames being less easy to manage. If possible, the soil in the deeper cold-frames should be raised near to the glass by sinking the sides of the frames to the necessary depth. At this season I lift the plants bodily, and after carefully relieving the roots of as much soil as possible divide the clumps into as many pieces as possible. Assuming the old stools elongated growths were cut back last autumn, the shoots are now stout and short-jointed, and the plant should break up into pieces quite easily, each piece having plenty of roots adhering. A few of the older pieces are likely to have a number of very long and coarse roots firmly attached, in which case the roots should be cut back to some extent, so that they can be the better handled. Such drastic treatment of these older pieces should give no cause for alarm, as they soon make vigorous root action. If two frames can be utilised, place the rooted portions in one frame. Do not be afraid of planting these divided portions of the old plants deeply, as they succeed so much better when treated in this way. The shoots which are broken off in course of dividing up the old clumps should be inserted in a small frame by themselves. Before inserting these broken shoots they should be made into proper cuttings, cutting the shoot immediately below a joint and trimming off the two or three lower leaves. When ready for insertion in the cutting-bed the shoot should not be more than 3 inches in length. Cuttings measuring between 2 inches and 3 inches in length are the best. Dibble in the cuttings, pressing the soil firmly at the base of each one, and take care that the cutting does not "hang." Deal with one variety at a time, and label each one before proceeding with another. The cold frame into which the divided portions of the old plants are put will not need to be watered for some time. It is wise to keep the frame close for a few days, after which admit just a "crack" of air. As these pieces begin to grow, more air should be given, increasing the quantity from time to time. With the advent of more genial weather the lights may be entirely removed, and when the plants appear to be dry give them a thorough watering. The cuttings should receive very similar treatment, only in their case they should be watered, using a flowered can, and it will also be necessary to keep the frame close rather longer. By these means it should be possible to have a batch of healthy and vigorous plants ready for planting out in their flowering quarters in good time in the spring.

D. B. CRANK.

YUCCAS.

THESE noble plants, with their distinct foliage and tall spires of ivory-white bells, are of estimable value in the garden, since they combine hardiness with sub-tropical effect, and when once planted increase in dimensions and beauty from year to year. Where sufficient space is available, Yuccas are never out of place, and are useful for a variety of sites. Perhaps they never create such a striking picture as when forming a large group on the grass backed by evergreens. The numerous heads of varying size composed of sword-shaped, spiko-pointed leaves, some standing erect above the ground-level, and others resting their lower blades upon the grass, are picturesque in their outlines and grouping at all seasons of the year, and become particularly attractive when in the autumn a dozen or tall flower-spikes tower aloft above the long grey-green foliage. As a break in a long herbaceous border Yuccas are valuable, a group of three or more plants coming well forward in the border giving a sense of formality by arresting the eye travelling down the long line of flowers with the relief of sterile foliage. As single plants on a lawn Yuccas are decorative, and as the centre of a bed a plant forms an effective foil to the flat brilliancy of Zonal Pelargoniums and Tuberosus begonias. Yuccas look well in the rock

from that species, for in addition to its arching foliage being totally distinct from the stiff leaves of the latter, the individual flowers are far more sparingly set on the spikes. It is almost as robust a grower as *Y. gloriosa*, and may be similarly treated when selecting sites. It is sometimes known as *Y. recurva*.

Y. FILAMENTOSA.—This is a dwarfier species, seldom exceeding 5 feet in height. Its specific name is due to the thread-like filaments that hang from the edges of the sharply-pointed leaves, which together have earned for it the title of Adam's Needle. It is a very free bloomer, and generally flowers unusually, and being of less vigorous growth is suitable for quite narrow borders, and for positions where the two former species would be inadmissible on account of their size. This and the next-named species are Yuccas for small gardens, and in spacious grounds they should be added to those already mentioned in this note.

Y. FLACIDA.—This is by some thought to be merely a variety of the last-named, but it differs from it in that the older leaves are abruptly bent so that they appear almost broken, it is also somewhat dwarfier, rarely exceeding 4 feet in height. The flower panicles of the two latter species are more branching than those of *Y. gloriosa* and *Y. pendula*. All the four here named are natives of North America.

lawn which takes two men with a lawn mower three hours to cut. How do you advise me to deal with it? It forms a very attractive feature of the garden, and I am loath to let it grow wild. It has some fine old trees on it—a Chestnut, a Mulberry, and a Silver Birch. Would it be possible to turn sheep on it without damaging the flower beds, separated by a gravel path?—RETTON.

[Your position is apparently an unfortunate one. It would indeed be a pity to allow the garden to run wild, and the only possible way is to keep the Grass cut, which is equivalent to more labour, which we imagine you wish to avoid. By naturalising the cheaper bulbs in the Grass you have at once a good excuse for a semi-wild condition and rural beauty at small cost. In this way, by once mowing the Grass early in the season you could allow it to go until there were no more flowers to open on the Grass. If you allow sheep thereon it will be necessary to protect the beds in some way. If sheep are admitted to the green pasture we cannot advise you to plant bulbs in the Grass. If you have no other use for the animal, a donkey controlled by lads should be able to do the mowing quite easily. What we object to in the sheep is the fact of their leaving all such rough Grasses as Cocksfoot, etc. This in time would be most unsightly in itself. Beds planted with shrubs would modify the space but not the cost or the labour for the time being. We wish you had given us more particulars of the surroundings to guide us.]

GARDEN PESTS AND FRIENDS.

CANKER IN FRUIT-TREES.

TO THE EDITOR OF "GARDENING ILLUSTRATED."

SIR,—I think that your correspondent, Mr. Sam D. Lytle, would do well to write to the Secretary, Board of Agriculture, 4, Whitehall-place, London, S.W. (no need to stamp the letter), asking for leaflet No. 56, issued in August, 1899, on "Canker in trees." It is well illustrated, and is sent gratis. The note in your issue of 5th July (No. 1217, p. 246) was merely a reference to a French gardening review, and what the M. fruit there quoted may mean by "chloridic acid" is not clear. The Board of Agriculture recipes are simple: 1 lb. sulphate of iron to 1 gallon of water, or else 1 lb. sulphate of copper to 5 gallons, to be applied two or three times during the winter. Since canker is quite likely to follow attacks of plant lice, whether American woolly aphid or any other sort, this treatment is pretty sure to do good. During winter the aphid pests are out of sight, but if their lurking-places are smothered with soft-soap now there will be fewer to deal with in the summer, when the treatment given in your article of the 14th January ought to do justice to them. There is nothing the American sort curls up in quicker than the petrolum or "kerosene" of its native land, applied as you recommended. They do more harm in a month than canker fungus does in five years, I fancy, as they fly and are blown by wind from tree to tree, and multiply so very fast; besides that, they carry spores of the canker too. May I add that popular names are peculiarly misleading. Blight meant originally decay caused by lightning, but we apply it to insect pests. Mildew meant honeydew, but is now used to mean a fungus growth. So also canker in origin implied an eating away by mites or insects thought similar to crabs, now it means the fungus *Nectria*. A REGULAR READER.

Pests in garden.—Last year my garden was badly infested with ants, earwigs, spiders, etc. Would a dressing of lime be of any good? If so, how much per square yard? Would it injure any bulbs I planted last year?—PAUL NEVON.

[A dressing of lime would not be of any use in destroying the insects you mention. Unless it was a very heavy one it would have no effect upon the ants. Any earwigs that were in the ground would simply move away to some other shelter, which they would probably find at no great distance off, and the spiders, on second thoughts, you would hardly wish to molest, as they are perfectly harmless in gardens and kill a large number of insects. The simplest way to destroy ants is to find out where their nests are, and then when the insects have retired for the night, to open them with a spade and pour in boiling water. If the nest he formed too near the roots of some plant to do this with safety, the plant had better be first removed.

Yuccas on the Grass.

NOTES AND REPLIES.

A purple Clematis, a Jackman, I think, which is usually out down in February, is putting out such long new shoots from roots, and on old wood on top of arch, that I hesitate to cut it down this spring. Will it bloom as freely if left alone?—G. M. H.

[Provided the Clematis is really a Jackman, or of this type, it will flower quite as well, possibly more freely, on the let-alone principle than when pruned. The flowers individually, however, may be a little less fine. The strong and new growths from the base should receive every encouragement, as these in grafted plants, provided they issue from the scion or trunk portion, as opposed to the grafted or underground portion, virtually renew the lease of life to the plant. It may not be easy to distinguish where such shoots issue from, and if deeply planted it can only be decided by differences of leafage. If the foliage from these new shoots now pushing from the roots is distinctly smaller than in the top growth, and not smaller only but decidedly inferior, you may be justified in assuming the ground shoots to be those of the stock and not the scion. When the two are in growth the difference will be obvious, and the removal of the ground shoots should be at once decided upon. One of the main objects in the annual pruning of these Clematises is that of securing clean growth, free from dead wood and such encumbrances. There are hosts of instances, however, where the plant has been grown on year after year without pruning at all, and though forming a tangled, more or less impenetrable mass, flowers well on the outermost shoots each year.]

Circle Garden.—I have a garden of from two to three acres to manage without a gardener, and without very much of my own to give to it. There is a large

garden, and make a telling contrast to the dwarf subjects with which such a site is for the most part filled; in fact, it may be said that well-developed specimens of these hardy plants are, whatever may be their surroundings, as worthy of admiration as any tender sub-tropical subject that can only be removed from a glass-house to the open garden for a few months in the summer. There are many species of Yucca, but for all practical purposes the following four will suffice for garden decoration.

Y. GLORIOSA.—This is a fine species, sometimes attaining a height of 10 feet. Its tall and imposing flower-spike is composed of many hundreds of pendent ivory-white blossoms very closely set which form a solid spire of flowers. Its leaves are rigid, wide, and terminated by a sharp spike. Though handsome as a single plant, it is seen at its best when a dozen or more are planted in an informal group, each plant being distant 6 feet from its nearest neighbour. When these have grown to a flowering size they form an exceedingly handsome feature in the landscape and eventually grow into an impenetrable mass with branching stems and *cheveux-de-frise* of sword-leaves, from which, in the flowering season, numerous tall bloom-spikes arise.

Y. PENDULA.—This, the subject of the accompanying illustration, is perhaps the most beautiful of all the Yuccas, its curving leaves giving the plant a very graceful appearance. It is considered by some authorities merely a form of *Y. gloriosa*, but differs considerably

Advertisement for 'Circle Garden' or similar, partially obscured by the text above.

URBANA-CHAMPAIGN

If the nests are in lawns, the Grass must be rolled back from the entrance to the nest for a foot or so. The inmates of a nest are so numerous that it is almost impossible to destroy them all by trapping them. When the earwigs begin to be troublesome again, lay pieces of folded sack about on the ground near the plants they infest, and hollow stems, such as those of Beans, Sunflowers, etc., among the shoots and leaves, and examine the traps every morning.—G. S. S.]

INDOOR PLANTS.

GROWING AMARYLLIS, ETC.

Will you through your correspondence column say when is the time to buy and pot Hippeastrums or Amaryllis, Arum Lilies, and Caladiums? If your space allows, will you add a few cultural directions?—W. H. OXLEY.

[Hippeastrums or Amaryllis, and Caladiums, may be bought and potted at once. The advantage of purchasing them now is that being still dormant they can be sent for a considerable distance at a little expense. Arum Lilies, on the other hand, are in full growth, so that you can only obtain them established in pots. They are never really dormant, but their resting period is from midsummer onwards for a month or so. In the case of the

HIPEASTRUMS, a suitable soil for them may be formed of two parts loam to one part leaf-mould, and half a part of sand, the whole being well incorporated together. For ordinary-sized bulbs pots 5 inches and 6 inches in diameter are ample. These pots should be clean and effectually but not excessively drained—say one good crock placed concave side downwards over the hole, with a few smaller pieces above it. In potting press the soil moderately firm, and leave just the upper portion of the neck of the bulb exposed. After potting very little water will be needed till growth recommences, but as the leaves and flowers develop far more will be required. They will need a temperature of 55 degs. to 65 degs., with a corresponding increase as the sun gains strength. After flowering they must be encouraged to make good growth, and in the latter half of the summer be well exposed to full sunshine in order to thoroughly ripen the bulbs. As the leaves turn yellow less water must be given, and during the winter they may be kept perfectly dry.

CALADIUMS vary considerably in the size of their corms, hence no particular size of pot can be recommended. As a rule, however, pots 3 inches to 4 inches in diameter are large enough to start them at first, as it is much better to treat them in this way and shift into larger pots as they require it than to pot them into the large pots at first. As with the Hippeastrums, very little water will be needed till they start. Caladiums are essentially stove plants and will need a temperature of 60 degs. to 70 degs. During the summer a reasonable but not excessive amount of shading is beneficial.

ARUM LILIES are quite greenhouse plants—that is to say, a temperature of 45 degs. to 60 degs. will suit them. If you purchase them now as growing plants, except keeping well supplied with water they will give but little trouble. By June they will have lost their freshness, when they may be stood out-of-doors in a sunny spot. Under this treatment they will become partially dormant, and about the end of July may be shaken clear of the old soil and repotted. They can be again stood out-of-doors and kept watered when they will grow away freely. Take them under cover when the nights get cold.]

Tuberoses.—Those who wish to grow Tuberoses should procure now the American bulbs, selecting those that are the strongest, using a compost of loam, peat, and sand, with some well-rotted manure. If the compost is in a fairly moist and workable condition at the time of planting there will be no necessity to water at all until growth has commenced, and, as soon as this is evident, then they may be placed in a pit or propagator where a minimum temperature of 60 degs. to 65 degs. is maintained, plunging the pots in some light warm material as Cocoa-nut-fibre if bloom is wanted early. When grown has well commenced

water may be supplied liberally, and when buds show they will derive considerable assistance if liquid-manure is given, but moisture must not be overdone. Regard must, of course, be paid to the temperature in which the Tuberoses are growing—a temperature of 65 degs. suits them to perfection, as in this they bloom freely. They dislike sudden changes, and that is why some fail to succeed with them, especially with the South African bulbs which are potted in early autumn for winter blooming. For button-holes, bouquets, etc., they make charming additions.—TOWNSMAN.

THE SWAINSONIAS.

In a greenhouse heated with hot water from 55 degs. to 65 degs. F. I have a Swainsonia (white) which keeps growing all winter, but not flowering in winter. It has six or seven runners 5 feet or 6 feet long. Must I cut them down now and treat it as an herbaceous plant, or tie them up to wires?—A. B.

[The Swainsonias are pretty, free-flowering plants, whose Pea-shaped blossoms vary in colour from white to pink and a kind of reddish-purple. *S. galegifolia* and its variety *alba* are the best, and will either flower freely in fairly small pots, or under more liberal treatment develop into climbing or, more properly, rambling plants that may be employed for furnishing a rafter in a greenhouse or for a

hurried in their growth. Leaf-mould and old loam, with a good proportion of silver-sand finely sifted, the roughest placed at the bottom of a well-crooked pot or pan and the finest at the top, is the compost best suited to their requirements, scattering the seeds thinly, and thus guarding against overcrowding in the first stage. See that before sowing the soil is neither too wet nor too dry. After making it level the seeds may be placed thereon, and gently watered in with a fine-roset pot; of course, if the soil is damp no moisture need be given for a few days. Place the pans on the staging in a cool-house—one, say, with a north or north-west aspect—or in a cold-frame on a north border. Over the pan or pot it is best to place a sheet of glass, covered on one side with whitening or paste, or a sheet of paper, to prevent moisture evaporating too quickly, just leaving sufficient space to admit air. When the plants are near the covering it should at once be removed, taking care that the seedlings do not want for water. When should they be removed from the pans? When they begin to touch each other, and by this time the second leaf has appeared. With this in view, one should prepare small pots, still giving plenty of drainage material and using the previously mentioned compost. Place one plant in each pot, and put them in a cold-frame, standing

Swainsonia galegifolia "alba."

similar purpose. A healthy specimen will flower from midsummer or even earlier, so that the season of blooming is spread over a considerable period. The flowers, which are produced in erect racemes from the axils of the leaves, are nearly as large as those of a Sweet Pea. Seeds are often easily obtained, and the Swainsonia will strike readily from cuttings, which is by far the better plan where dwarf plants are required. They may, however, be kept and flowered year after year if cut back in the spring and repotted when they have started into growth. All through the growing season the Swainsonias require abundance of water, but in the autumn, when they cease growing, and during the winter, only give enough to keep the soil fairly moist. You have evidently watered your plant during the winter when it should have been allowed to rest.]

HERBACEOUS CALCEOLARIAS.

In nine cases out of ten failure to grow these beautiful showy plants may generally be attributed to giving too much heat and overcrowding. To have them in bloom early in May, seed should be sown the previous June, in order to give the plants the longest period of growth, instead of, as is not infrequently done, making a sowing in July and August, and pushing the plants along under glass. It is always well to remember that in connection with the growing of herbaceous Calceolarias they will not be

them on a bed of ashes, and thus prevent any chance of their becoming prematurely dry. For the second removal, which should be immediately it is seen the roots are well rooted in the pot, one may add to the compost partly decayed cow or horse-dung—the former if it can be obtained, as it is cooler—and in shifting them the "collar" of the plant should not be buried, as it predisposes to damping off.

In September a change from the frame will be necessary, as from about the middle of the month the nights become cool. To this end room should be prepared for them in the greenhouse, and instead of arranging them with other plants, it is much better to have them all together where their wants may be easily looked after. Do not keep the ventilators closed and pack them together, but give them what room can be spared, and just enough fire-heat to keep damp out of the place. Watering should be done in the morning, and the water ought to be tepid. During the winter maintain a steady growth. Those who have plants in their houses now will be well advised in giving them a stimulant twice a week—not too strong—weak liquid manure or guano. Presently the flower-stems will be showing above the foliage, and these should be tied to thin stakes. Do not attempt to hurry the plants into bloom by increasing the temperature of the house. I would rather have a group in flower in May by maintaining a temperature of 55 degs. than have them in

blossom in April in an atmosphere of 65 degs. with green-fly lurking under every leaf. Herbaceous Calceolarias are amongst the handsomest of our greenhouse flowers, but many "coddle" them, instead of maintaining a cool treatment from seed-sowing to blooming time.

LEAHurst.

NOTES AND REPLIES.

Franciscæa.—I have a nice plant of Franciscæa which was full of bud, but after a few of the flowers had opened most of the buds fell off. It is in a stove facing west, and catches a good deal of wind, so that the temperature varies a good deal. Will you kindly tell me the treatment necessary, and if it requires feeding?—A. B.

[The Franciscæa is essentially a stove plant, and doubtless the reason of the buds dropping is that the plant has sustained a severe check of some kind, in all probability caused by a considerable drop in temperature, which, according to your note, varies a good deal. The coldest period of the day is often in early morning, and as the fire is then usually at its lowest ebb, it is more than probable that the mischief was done at that time. The temperature even in winter should not fall below 55 degs. The cultural requirements of the Franciscæa are the same as are needed for the majority of stove plants—that is to say, a compost of equal parts of peat and loam, with a liberal sprinkling of sand, and shading from bright sunshine during the summer months. If thoroughly well rooted a little weak liquid-manure may be given occasionally (say three or four times) during the summer when in full growth, but even without this the plants may be kept in good condition.]

Leggy Camellias.—I have seven Camellias which have long, straggling branches, naked all the way up except at the points. If I cut them back now, can I get them to throw flower-buds for next year? How can I plant the cuttings to succeed in getting them to grow?—A. B.

[You may cut back your Camellias as soon as possible, or if you require the present crop of flowers it should be done directly they are over. After cutting back give only enough water to keep the soil fairly moist, but a drenching over with the syringe three or four times a day, particularly if the weather is bright, will be very beneficial. However well they break out after the operation, you cannot expect anything more than a solitary bloom or two next year. Camellia cuttings are extremely difficult to strike, and we cannot hold out much hope of your attaining any great measure of success in this respect. The best chance will be to form the cuttings of the tops of the last year's shoots. Six inches is a very suitable length for them, and if cut off at a joint and the bottom leaf or two removed, they are then fit for insertion. For this purpose take some clean 5-inch pots, put broken crocks in the bottom to one-third of their depth, then fill with a mixture of equal parts of loam and sand, passed through a quarter of an inch sieve. Press this down very firmly, dibble the cuttings therein, give a good watering through a fine rose, and then cover with a bell glass, or place in a close propagating case in a shady part of the greenhouse. After a couple of months or so a little more heat will be beneficial, but you must be prepared for failures.]

Hydrangea Hortensia.—I bought recently at a sale some Hydrangea Hortensia in pots, and shall be glad if you will give me some hints as to culture? They are, I believe, gross feeders, but seem to me to be very pot-bound. Would it be wise to repot now? They are just coming into leaf at the tips: they have not been pruned for some time. Would you advise planting out later on, plunging, or growing on in a cold-house?—E. C.

[As your Hydrangeas are so much pot-bound, it will be wise to repot at once, but, as the leaves at the tips are just starting, do not disturb the roots to any great extent. A suitable compost may be formed of two parts loam to one part each of leaf-mould or peat and well-decayed manure, with a little sand. In potting, press the soil down moderately firm, and leave a good space at the top for watering, as during the summer months copious supplies will be needed. We presume the plants to which you refer are growing in the cold-house, in which case the better way will be to keep them there till the month of May, when all danger from frosts being over they can be plunged out-of-doors, taking care that they are not allowed to suffer from want of water. Your letter is headed from the south coast, where the Hydrangeas should be hardy, and if such be the case you may, if you prefer it, plant them out,

but as they have already started while under glass, the planting should not be done till all danger from frosts is over. If kept altogether in pots, a little weak liquid-manure during the growing season is beneficial.]

Striking Gardenias.—My Gardenias are beginning to grow. Would you kindly tell me the proper method of striking same, as I am very unsuccessful in striking them?—READER.

[Gardenias may be readily propagated from cuttings at any time during the spring months. Shoots of medium vigour make the best cuttings. These should be cut off cleanly just below a joint, removing the bottom pair of leaves. A very suitable length for the cutting is about 4 inches. They should be inserted into small pots filled with a compost consisting of equal parts of loam, leaf-mould or peat, and silver sand, made moderately firm. After this, place them in a close propagating house in the stove, or, at all events, where a minimum temperature of 61 degs. is maintained. They will root in about a month, when more air must be given, and the plants gradually inured to the

moaly-hug, and scale, but all these can readily be kept in check by any of the numerous insecticides that are now obtainable.]

BROWALLIA SPECIOSA MAJOR.

THIS, which we figure to-day, may be had in bloom at all seasons, but during the winter months it is, perhaps, most appreciated, though at that time, should the weather be dull, the flowers are scarcely so bright in colour as those that expand in the summer. It is a plant of easy culture, and easily increased either from cuttings or seed. Cuttings of the growing shoots strike root as freely as a Fuchsia, while seed which frequently ripens germinates quickly. Good specimens may be grown in pots 5 inches or 6 inches in diameter. When raised from seed, about half a dozen plants pricked into a single pot and grown on without further disturbance are very effective. Cuttings are best grown three in a pot. The flowers, which are produced in great profusion, are of a beautiful shade of blue with a light

Browallia speciosa major. From a photograph by Mr. Geo. E. Low.

ordinary atmosphere of the structure in which they have been. Then, in a week or two, shift into pots 4½ inches in diameter, and pinch the points of the young shoots from time to time, in order to lay the foundation of a good, bushy plant. If they are grown on freely in a stove temperature the plants will by the end of June be ready to shift into 6-inch pots. By the end of August they must be kept somewhat cooler; a minimum temperature of 55 degs. will suit them in the autumn and winter, when, on the return of spring, the flowers will soon open. This is the quickest way of obtaining good flowering plants; but where conveniences for this do not exist the Gardenia may be grown in the warmest part of the greenhouse, but its rate of progress is then, of course, slower. Under this cool treatment it will take two seasons to form effective specimens. It is by no means necessary to have young plants every year, for they may be kept for many years in a perfectly satisfactory state. A compost of two-thirds loam, one-third leaf-mould, with a little rough sand and a little cow-manure, will suit Gardenias well. They are liable to be attacked by aphides,

centre—that is, when first open, for after a time they become paler, and, singularly enough, also increase in size. A mixture of loam, leaf-mould, manure, and sand will suit this Browallia well. As the pots get full of roots occasional doses of liquid-manure are very beneficial, the flowering season being greatly prolonged thereby.

Sparmannia africana.—A couple of starved plants of this Sparmannia are in the warmest part of the greenhouse, each bearing several clusters of their uncommon yet charming blossoms. These, which are borne several in a loose head, are about an inch and a half across, and composed of four white petals of a delicate satiny lustre. By far the showiest portion of the inflorescence, however, consists of the large globular cluster of stamens, the basal half of which is of a rich golden-yellow, while the upper portion is crimson-purple—a very marked contrast. It is by no means a novelty, having been introduced from South Africa in 1790. It is a very easy subject to propagate from cuttings, and it also grows

with great freedom, but many fail to flower it in a satisfactory manner. The principal reason of this is the plants are grown too freely, perhaps, in a more or less shady structure. In this way they soon form large bushes, clothed with luxuriant heart-shaped foliage, but thin in texture, while flowers are very few. To ensure a good display of blossoms the plants should, during the latter part of the summer, be stood out-of-doors in a spot fully exposed to the sun in order to thoroughly ripen the wood. They will not need repotting every year, but, if necessary, may be assisted during the growing season by a little manure-water. Being naturally a large shrub or small tree, pots 10 inches to 1 foot in diameter are about the smallest size in which effective specimens can be grown. Early spring is the usual season of flowering, but the clusters of bloom on my plants now are very welcome.—W.

CHRYSANTHEMUMS.

NOTES AND REPLIES.

A good late Chrysanthemum—Mme. Felix Perrin.—During the latter part of December there is no Chrysanthemum of a pink colour to compare with the Japanese Mme. Felix Perrin. Some trade growers describe the colour as soft rose-pink, but this is hardly correct. As a matter of fact, when grown in the country, the colour is a very lovely shade of soft pink. This kind is now largely grown for market, and at this late season bunches of bloom may be seen in almost every florist's shop. This variety should be grown to develop its blooms freely, and with this object in view, should be stopped or pinched several times during the growing season. No pinching or stopping should, however, take place after the early days of July. The plant has a good constitution, and grows about 4 feet high.—C. A. H.

Late-flowering Chrysanthemums failing.—I cannot succeed with late Chrysanthemums, notably Princess Victoria and W. H. Lincoln. I usually root cuttings about February and pot on by degrees into flowering pots end of May, leaving outside till October, sometimes, as this season, later. They do well all the summer, but, when removed into cool greenhouse, buds invariably go blind. I feed them along with others from July onwards, and the only reason I can suggest for failure is that when atmosphere gets damper, with more rain, less manure must be used, and that, consequently, buds are starved. Is this so, and how can it be avoided?—A. MATHER.

[We are at a loss to explain the cause of your failure with the late-flowering Chrysanthemums. At any time during the present month or in March insert cuttings of any late-flowering kinds you may have stock of. Give the cuttings and young plants subsequently fairly cool treatment. Pot them up from time to time as they need it, and three or four times during the growing season pinch out the point of the shoots of the plants. Never stop or pinch the plants at the same time that they are repotted. We are quite satisfied you made a mistake in finally potting your plants so early as May. We should be disposed to leave the final potting until quite the end of June or July even. The last pinching should take place towards the end of July. Give the plants a good open position during the summer and early autumn, in this way encouraging the development of sturdy, well ripened wood, without which you cannot expect to achieve success. No manure-water should be given until the pots are well filled with roots, and at first the doses should be weak and often applied. Terminal buds in the ordinary course of events should develop late in September or early October, and, if the plants are nice and bushy, they should be disbudded to one bud on each shoot. Keep the plants outdoors as long as possible, only removing them under glass when frosty weather threatens. Ventilate the house freely, always avoiding draughts. While the buds are swelling satisfactorily keep the house in a cool condition. All that is needed is to see that frost is excluded. As the buds progress and many of them begin to show colour it will be necessary to keep the air of the greenhouse in a more buoyant condition. You must keep the hot-water pipes sufficiently warm to dispel moisture and also to assist the development of the unfolding flowers. Observe this system of culture, and you should, we think, succeed.]

VEGETABLES.

FORCING ASPARAGUS.

THIS may be forced in many ways, and had from November onward. Some people think it is an expensive commodity, but this is not so if room can be found to grow the roots. These may be raised from seed, but where space is a consideration I prefer to purchase good three-year-old roots. These, if planted in good soil in rows 20 inches apart and a foot from plant to plant, make fine crowns in two or three years. In this way a good many roots may be had from a small space. I prefer these strong young roots to weak old ones that have been exhausted by cutting. Radishes or Lettoes may be grown between the rows the first year, as these come off quickly. In this way the Asparagus does not occupy the ground long. Land that has been trenched for Onions or used for Celery does not need much preparation beyond levelling. To have good forced Asparagus it is important the roots should be strong, and that no grass has been cut the previous year. In this way all the strength is concentrated in the crowns. The more roots can be had when lifting the better the results.

Given good roots, forcing is a simple matter, seeing they may be brought forward in any glass structure, placed on a bed of leaves, or anything that produces a gentle heat, with rough boards round to keep the soil and roots in position. On these garden lights or any glass frame may be placed. Lacking these, shutters or even mats will do. This rough-and-ready method is only suitable for late crops, seeing Asparagus must have light to produce flavour. I have seen splendid Grass grown in vineries by placing the roots on the border and covering with leaf-mould. When the Vines are started at the beginning of the year, it is easy to bring it on, as the moisture and heat that are suited to the Vines are just the thing, and by the time the Vines are in bloom the Asparagus is about over. Some three years ago, when visiting Rood Ashton, near Trowbridge, in early spring, I was impressed with the way Mr. Strugnell was forcing Asparagus under the front of a stage in a warm plant-house. Although some of the roots were near the hot-water pipes, they did not effect it, seeing it had a good covering of material that held water. In a general way, hot-beds in pits and frames are brought into use for this crop, which is an easy and simple method. I obtain a supply by placing roots on a bed in the centre of a vinery, and in this way I bring forward this with the late Grapes. I usually fill this bed about the middle of January, and in about three weeks I am able to cut the first dish. For years I disliked seeing the bare soil that covered the roots, and I resolved to try sowing a quick-growing Radish on the surface at the time of covering the roots. As these beds are raised 3 feet to 4 feet above the level, they are well up to the light. From this I soon obtained a good supply of tender roots. J. CROOK.

NOTES AND REPLIES.

Early Cabbages.—Where these were put out in shallow trenches—and it is much the better plan to do this than plant on the level—the soil should be pulled around the plants. This will steady the plants against winds, and shelter them should hard frost or cutting east winds set in, the latter always playing more havoc with green stuff than actual frost.

Using a bed of leaves.—I have a bed of leaves 2 feet deep in a long trench covered with a few inches of soil, in which I propose to start a few vegetables. When done with, should I fork it up and spread it over beds, or grow a crop of Onions on it as advised by a neighbour?—MORAY.

[On the bed of leaves in a trench on which you have but a few inches of soil you will presently, as the leaves decay, find it needful to place more soil before you plant it, or it will be too shallow. Grow Runner Beans for choice on the trench, then next winter throw out decayed leaves to dig in on other ground, and refill the trench with fresh wet leaves and treat it as before.]

Drills for Peas.—I should be very much obliged if you would kindly tell me through GARDENING what length of drill 1 quart of early Peas should be made to sow, also the length of drill 1 quart of late Peas should sow?—W. S.

[Usually a quart of early Peas is sufficient to sow a row 1½ feet in length, while the like quantity of a late variety will cover a row 2½ feet in length.]

may well do a row 130 feet long. It is wise to sow a bit thicker in early spring, because the mice are a much greater nuisance during February and March than they are in the summer months, and it sometimes happens that the weather in these two months proves exceptionally cold and wet, which is against germination of seeds in the open garden. Later sown crops are not so handicapped, and the individual plant does very much better when the haulm is allowed plenty of space to spread about, and it is also better for the roots when not unduly crowded with those of its neighbours, and the plants continue to crop much longer, when light, sun, good air can penetrate well among the branches. Last season being very much against a good harvest of seeds, it is advisable to sow a trifle thicker, and not commit seeds to the ground in too great a hurry. For better results will accrue if such work be postponed until the soil is in a more congenial state.]

Brussels Sprouts clubbed.—I have had a very poor crop this year. The garden was virgin soil six years ago. A great many are quite clubbed at the root. I should be grateful for advice on the subject?—I. ALFRED DAVIS.

[Whether the clubbing of Brussels Sprout plants, of which you complain, be due to a tiny maggot or to a fungus, the best preventive is an application of gas-lime, at the rate of about a bushel per two rods. Spread about evenly, well broken, then allow to lie exposed to the weather, and later dig it in. It is best to do this in November, allowing the lime to lie exposed for four weeks, then digging it in. If you cannot get gas-lime, then dress the ground on which you propose to plant the Sprouts with ordinary lime. That can be used just before the planting is done. Put down bushels of lime fresh from the kiln in heaps for each two rods, and cover up thickly with soil. It will soon slack; then spread it about and dig in. Do not plant Sprouts where they have grown this winter, but in fresh ground. When you have the plants, look over the roots, and if you see any swellings on them cut them off. Dip the roots into a solution of soft-soap, soot, and clay, well stirred, before you plant. Have the ground deeply dug, and plant end of June, or as soon after as possible. Brussels Sprouts like a fairly firm soil.]

Storing stable manure.—Kindly tell me what to do with ordinary stable manure which contains a lot of straw? By keeping it, will it ever become really manure? Ought one to have a cement pit for it, and if so, how should it be made? Should the manure be kept under cover, so that rain and sun cannot affect it? If you can get into the subject thoroughly, you will benefit many of your readers, who, like me, are very vague on the subject.—H. TRENKLEMAN.

[When stable manure contains an excess of long straw, the wisest course to take is to shake out a quantity of this, allow it to dry, then either use it to bed pigs, cows, or horses again, or else make a stack of it on a dry base and cover it from rain, so that it can be used to shake over seed-beds or early Potatoes, or lightly over outside Vine borders, or for any similar uses. If not so removed from the manure the proportion of straw is to the real manure far too great. If left with the rest, then the best course is to turn the heap frequently, casting over it all sorts of horse-slops or water to cause the straw to more rapidly decay, as until it is in an advanced stage of decomposition it is practically useless as manure. When stable or any other animal manure has to be stored in the open, it should always be on a hard floor, such as one of concrete or cement, the floor being a little hollow or concave, so as to retain any liquid that may exude from the manure. If a pipe were laid from the heap to a big tub or cistern sunk in the ground, the whole of this liquid could be caught and utilised, really at any time of the year except in hard frost, as liquid manure. It would most likely need to have its bulk doubled, or even trebled, by the addition of water before being used. Even if the manure be so stored it should be turned now and then not only to check fermentation, but also to ensure equable mixing and decomposition. If manure cannot be so treated, then it is best to store it under a shed, but even then frequent turnings are needful. So covered there is practically no loss. On the other hand, in the open, what fertile property is washed out of it is secured and utilised in the liquid manure, which is, after all, one of the most effective ways of manuring crops.]

GARDEN WORK.

Conservatory.—One of the best forcing shrubs is *Prunus triloba* *flora-pleno*. Good-sized bushes may be had in 6-inch and 7-inch pots, and it does not require a very high temperature to get them into flower in January. After flowering, prune back and get the new growth made and a little firm before plunging them outside. Just the same treatment usually given to *Deutzias* will suit the *Prunus* family. Bulbs are making a brave show. Narcissi are very effective, and those who are foreign English-grown bulbs find them as useful as those imported from Holland. The most disappointing bulbs this year have been the Roman Hyacinths, which have not only been inferior, but much higher in price. The small Italian Hyacinths are not only cheap, but come as early as early, and are altogether much better and finer, and may be had in several colours. Solomon's Seal forces easily, and, being a British plant, may easily be grown at home in any good ordinary soil. *Horbaucosus Spiraeas* recently imported will soon be in bloom and make a charming group. Those kept in cold storage chambers have been in flower some time, but this adds to the cost. A bulb or plant which has been retarded in this way starts away with much less heat than others not retarded, so that there is something gained in the matter of fuel and time. Standard plants of *Roses*, *Scarlet Thorns*, *Lahurnums*, and *Almonds* when established in pots will force easily in a Peach-house at work, and such things are very effective among the dwarfier plants in the conservatory borders. There is a very heavy demand now for cut flowers, and to a large extent this has to be met by forcing bulbs and other things. I have already mentioned *Solomon's Seal*, and to this might be added the *Bleeding Heart* (*Dielytra spectabilis*). Long sprays of this and *Solomon's Seal* are lovely in tall glasses. Of course, *Lily of the Valley* and the *Narcissus* family will supply many beautiful flowers for cutting, and they are very popular everywhere. With longer days we may reasonably expect more sunshine, and more water will be required. It will be better for some time yet to do the watering in the morning, though this will not prevent a look round early in the afternoon if any plant requires it.

Propagating summer-flowering plants.—Those who have no regular propagating-house may do a good deal of useful work in an ordinary hotbed with the pots plunged in leaves or *Cocos-nut-fibre*. All soft-wooded plants, except *Geraniums*, will do well in a warm hotbed. *Cucumber* and *Melon*-frames are generally utilised for the growth of young stuff and raising seedlings till the *Cucumbers* and *Melons* require the space. The temporary tenants will do no harm if not kept in too long. When we used to do a good deal of work in this way now beds were continually being made for different things, so that there was always room for moving things on. This is necessary if much work of the kind has to be done. It is important also that a close watch should be kept for insects. Cuttings with succulent stems, such as *Geraniums*, will damp off if placed in the hotbed, but every cutting will strike if planted in sandy soil in shallow boxes, and placed near the hot-water pipes. Our boxes of *Geranium* cuttings are standing on the pipes, with a 3-inch board under them resting on the pipes. Those who have only a few cuttings may ribble them into pots, but with thousands to deal with boxes save both time and space, and by the time the cuttings require potting off other houses will be ready for them with the necessary warmth to give them a start.

Ferns under glass.—Maiden-hair and other Ferns which have more or less been at rest are now on the move, and if it is intended to divide any to increase stock the work should be done now or soon, and as soon as this is done give a little more heat to push them into growth. Young plants of various kinds in pots may have a shift. Seedlings in boxes should be potted off when large enough. If left starving in boxes they will want time to recover from the shock. *Adiantum Farleyense* may be divided into single crowns.

Work in the early vinery.—The young shoots should not be crowded. Ample room should be left for the full development of the foliage. For this purpose the young shoots should be reduced to something like 15 inches apart on each side of the rod. This may be taken as the average distance where a full crop is required. As soon as two leaves can be seen beyond the bunch, the terminal bud should be rubbed or pinched out. When the main rods are trained very near each other one leaf only will be left beyond the bunch, but two are better if there is room. Black Hamburgh and Sweetwater are good setters, and if the rods are topped with the hand or a padded stick when the pollen is dry and ripe, there will be a good set. Thinning may begin as soon as the berries are large enough to show which are taking the lead. Sublaterals below the bunches should be rubbed out, and others pinched to one leaf.

Mushroom-house.—Now beds should be made up as the old ones cease to bear. Enough has been said from time to time regarding the selection and preparation of the manure, which should be from hard-fed horses in good health, and the manure during its preparation should not be washed by rains. Spawn also should be good, preferably new, and should be inserted in firm beds when the temperature is steady at about 85 degs. Firmness in the beds is essential to obtain the best results, and the covering of earth, which should be about 1½ inches thick, should be beaten firm with the back of the spade. A covering of hay is useful in keeping in the warmth and moisture, though for a time after spawning the thermometer or watch-stick should be tested often, as sometimes the temperature may rise too high if too much covering is used.

Cold-frames.—Give air freely on mild days. Remove dead leaves from *Auriculas* and prepare compost for repotting. Good loam and a little leaf-mould and old cow-manure, with some coarse sand, will do this family well. Sow seeds of the *Primula* family in boxes, and give a little warmth to hasten germination. Keep *Carnations* on the side of dryness at the root, but with lengthening days and more sunshine more water will be required.

Outdoor garden.—*Roses* on south walls intended for early flowering, if not already pruned, may have attention now. Cut away all weak shoots and enough of the old wood to leave enough space to trim in the strong young wood of the past year, as this will bear the finest blossoms. When all are pruned and trained a syringing with an insecticide will be useful in getting rid of the eggs of insects. A *Rose* which has been severely attacked by insects takes a long time to recover, and prevention is better than cure in this case. There is plenty of time to plant *Roses* and other plants on walls, arbours, or pillars. I am not saying that November is not a better time, but I do not desire to fix a limit to the time, as very often the site is not ready in the autumn, and I would rather plant in March if the site were well prepared than put off till the autumn. It is merely a question of giving a little more attention to the plants in dry weather through the spring. Stir the soil among autumn-planted *Carnations* and *Pinks* when the surface is dry. Nothing encourages growth so much at this or any other season as stirring the surface to let in the air. Bulb borders, now that the plants for the most part are coming through, may be stirred up also. Box edgings may be replanted and walks turned over and regrevelled where necessary. Repair worn places on lawns, and top-dress with basic slag and nitrate of soda, or some other stimulant. We find ordinary weed-killer very good for killing *Plantain* on lawns.

Fruit garden.—The quarter given up to bush fruits, as soon as the bushes are pruned and dressed with lime and soot to keep off the birds, should be measured and forked over to let in the air to sweeten and pulverise the surface. Sometimes bush fruits are given the side of the walks. *Gooseberries* are sometimes trained to wire trellises, and this is a good plan where the fruit is required for dessert. Red and White *Currants* are often planted on the north sides of garden walks to fill in between the permanent trees of *Plums* and *Cherries*, and the fruits on the north wall

come in well for late use with the autumn-bearing *Raspberries*. But where many bush-fruits are grown it becomes necessary to group them together in one plot at regular distances apart, as under such conditions they usually bear better. Finish pruning and training *Raspberries*. The mode of training is a matter for individual decision. I have had good results by adopting the field method by growing the canes sturdy in an open position, well mulched and pruned down to 3 feet. In pruning *Blackberries* and the *Logan Berry* the weak shoots should be removed and the strong young canes left a considerable length for fruiting. There is yet time to plant both bush and other fruits. It may not always be convenient to plant in autumn, and if the ground is not in condition for planting it will be better to wait till it is.

Vegetable garden.—Old gardens now much benefited by a dressing of lime. Gas-lime may be used anywhere, even among growing crops, at the rate of a pound per square yard. On vacant ground double the quantity or more may be used. Ordinary air-elaked lime may be used at the rate of a bushel per square rod. Slugs and snails will be giving trouble now in mild weather. Such gardens are usually surrounded by tall hedges, or heaps of rubbish may be left lying about near the garden, and these form suitable breeding places for the pests. If a general clear up is given there will be a reduction in their numbers. Lime and soot used in mild, damp weather during spring will be useful. The weather is better now for sowing and planting and as soon as the surface is dry early crops of Peas, Beans, Potatoes, Cabbages, Lettuces, Horn Carrots, and Radishes may be sown or planted. New plantations of *Horseradish* may be made, and the ground trampled and manured for *Globe Artichokes*. Those who wish for early heads of *Globe Artichokes* usually put up a few roots and start them under glass and plant out when the weather is warm and settled in April. Draw a little earth up to the early Cabbages, and stir the soil everywhere. E. HORNAY.

THE COMING WEEK'S WORK.

Extracts from a Garden Diary.

February 15th.—We want plenty of early Peas, therefore several sowings have been made, and the earliest are up and doing well. A ridge of soil has been drawn up on each side of the row. Gradas is a favourite with us, though not quite so early as several others. We leave the early border now and sow long rows across the quarters. Put in cuttings of soft-wooded stove or warm-house plants, including *Euphorbia jacquieiflora*, *Begonias*, *Justicias*, &c. The propagating-house is kept full up now.

February 16th.—Early Potatoes are being planted now in sunny, open positions. Cauliflowers under handlights have been dusted with soot and earthed up a little. Other Cauliflowers are coming on—some in cold-frames, others in heat for succession, and just a few of Veitch's Forcing in 6-inch pots in pit for early use. These do not get very large, but the hearts are white and close. Liquid-manure is given as soon as the roots are numerous enough to use it. Planted out root cuttings of *Seakale*.

February 17th.—There is always work to do in the vineries and Peach-houses, especially where there are several of each. Potted trees in orchard-house are coming on quietly, and the blossoms will soon be open. Simply tapping the stems with a padded stick will scatter the pollen when it is dry and ready, if the house is sufficiently ventilated. *Rivero's Early Nectarine* is a valuable kind; so also is *Lord Napier*, which comes in succession. Among *Peschas* in pots the old *Royal George* still keeps its place. Insects are easily dealt with by vapouring.

February 18th.—Sowed seeds of *Potunias*, *Verbenas*, *Zinnias*, and *Phlox Drummondii* in heat. Replanted a long herbaceous border which had been treached and manured. This, of course, necessitated taking all things up. Some of the common things have been discarded, and other plants of better character introduced. The arrangement of the plants

has been chiefly in groups of contrasting colours, a few spiral-growing things being dotted about among the groups. Finished training Peaches on walls. Removed more of the covers from Figs on walls.

February 17th.—Put in more cuttings of various kinds of bedding plants. Shifted on early-struck Chrysanthemums and put in more cuttings for late blooming. Strawberries in pots swelling the berries are now having liquid-manure. Other plants are taken in from cold-frames from time to time as required, as when gathering there must be no break in the supply till they are ready outside. Covered a bed of Asparagus with old lights to hasten the growth and protect the heads from frost.

February 20th.—Earthen up early Potatoes in frames. The earth had been placed between the rows to get warm before placing it against the Potatoes. Sowed Spinach between rows of Peas. Thinned young Carrots in frames. Made up hot-beds for the Asparagus and more Potatoes. One small frame on a hot-bed has been filled with Lily of the Valley crowns. The frame will be matted up till some progress has been made. These warm hot-beds suit the Lily of the Valley, especially when the flowers are required in quantity.

AQUARIA.

Fresh water snails (J. M. C.).—For consuming decayed vegetable matter and keeping the water of the aquarium in a wholesome condition you would find the species *Planorbis cornuus* very useful. The shell of this snail is flat-coiled in shape, and is of a dark reddish-brown colour, while the body is black above and greyish underneath. Another snail which is a favourite with aquarium keepers is the "fresh water wrinkle" (*Paludina vivipara*). This snail has an oblong shell of a brownish-green tint. Another useful snail is *Bythia tentaculata*. This is smaller than the above, the shell being conical, of a yellowish horn colour. You would no doubt be able to obtain these of any dealer in necessaries for the aquarium.—S. S. G.

LAW AND CUSTOM.

A gardener's plants.—I am a single-handed gardener, and when I came here I brought with me cuttings, seedlings, and bulbs of different kinds. Can I claim compensation for any of them, or take them away?—G. G.
[You cannot claim compensation for these, but unless you have given them to your employer, or entered into any arrangement with him by which these have become his property, you may remove them.—K. C. T.]

Payment of tithe.—Am I compelled to send the tithe to the parson's solicitor, costing me 1d. for letter and 1d. for cheque? Is he not bound to call or send for it in the same way as any tax or debt is collected?—C. T.

[This point has never been decided in a court of law, but the general opinion is that the tithepayer is only bound to attend at the place out of which the tithe issues or in some place convenient thereto. So if the tithe is demanded in the parish where you live, you should take it or send it to that place, but if you are asked to send it elsewhere you may deduct the cost of the remittance. You are mistaken in supposing that it is the duty of a creditor to collect his debt; the contrary is the law, and every debtor is bound to seek out his creditor and pay him the amount due. To this rule there are certain exceptions, as where rent is not reserved under any written instrument, and in the case of rates.—K. C. T.]

Wire on boundary.—I own the house where I live, and my neighbour occupies and owns the adjoining house. The gardens are divided by a wooden railing, half of which belongs to each of us, and the fence is affixed to the centre of both houses. Cats and fowls enter my garden, and are a source of nuisance. Can I, without my neighbour's consent, place wire-netting on the top of the railings to keep the fowls and cats out?—CRON.

[If half the length of the fence belongs to you and the other half to your neighbour you cannot erect wire upon his half without his consent. If the whole length of the fence belongs to you both jointly, and the fence is a party-fence, I think you may erect wire upon it, attaching the wire to your side of the fence. It will only be courteous on your part to inform your neighbour of your intention, but if the fowls belong to him you may recover damages from him for their trespass, and you need not put up any wire to keep them out.—K. C. T.]

CORRESPONDENCE.

Questions.—Queries and answers are inserted in **GARDENING ILLUSTRATED** free of charge if correspondents follow these rules: All communications should be clearly and concisely written on one side of the paper only, and addressed to the Editor of **GARDENING ILLUSTRATED**, 17, Finsbury-street, Holborn, London, E.C. Letters on business should be sent to the Publisher. The name and address of the sender are required in addition to any designation he may desire to be used in the paper. When more than one query is sent, each should be on a separate piece of paper, and not more than three queries should be sent at a time. Correspondents should bear in mind that, as **GARDENING ILLUSTRATED** is sent to press some time in advance of date, queries cannot always be replied to in the issue immediately following the receipt of their communication. We do not reply to queries by post.

Naming fruit.—Readers who desire our help in naming fruit should bear in mind that several specimens in different stages of colour and size of the same kind greatly assist in its determination. We have received from several correspondents single specimens of fruits for naming, these in many cases being unripe and otherwise poor. The difficulty between you is of fruits, are, in many cases, not trying that it is necessary that three specimens of each kind should be sent. We can undertake to name only four varieties at a time, and these only when the above directions are observed.

PLANTS AND FLOWERS.

Tropaeolum for stags (C. M. H.).—The best *Nasturtium* for this purpose is the rich-coloured climbing form known as *Tropaeolum Lobbianum*, as it is slender in growth, and will drape a stage in a pleasing and informal manner. The best nurserymen offer several forms in their seed catalogues, and a very superior kind if true is *Tropaeolum Lobbianum Brilliant*, seed of which can be purchased at a moderate price.

Arum leaf damaged (Miss Garrett).—The leaf sent appears to be very thin in texture, as if it had been grown in a structure where very little air was given, and with moisture collecting on the leaves, they, from the lack of substance, quickly decayed. Do you use an oil lamp to keep out the frost, Arums quickly resent this? A sturdy plant with cut solid leaves will retain its foliage under adverse conditions much better than one that has been grown without a free circulation of air.

Hyacinths after blooming (Tulip).—Stand the pots outside in some sheltered place and cover them and the plants with light litter, so that they may be protected from frost. One may stand them in a frame, watering them until the foliage has died down. It is of no use relying on these for forcing again, and, when the weather gets settled about April, you should plant them out in a sunny border. They will then bloom every year, certainly not so fine as pot specimens, but still such as will repay your trouble.

Flowers from seed (Hastings).—You do not state whether you require annuals and biennials or perennials. In each set there are many that flower about midsummer, but to get them in perfection the seedlings should be raised at home. You do not say whether you have a frame or greenhouse or other convenience for raising such plants. Give a few more particulars, and we will try to help you. The ground should at once be dug deeply—at least 18 inches deep—and heavily manured as the work proceeds.

Passion-flower not blooming (C. W. M.).—Your Passion-flower seems to have unlimited root room, and we should also think that the structure must be considerably shaded, otherwise you should certainly have had many flowers. It may be kept within bounds by cutting it back to the old wood—that is, leaving the main branches which go up the rafters or roof, and removing all the flexible shoots. This should be done at once. We presume it is the common blue Passion-flower, in which case you may, if you like, plant it out-of-doors, choosing for the purpose a wall facing south or south-west. In this case the month of April is a good time to move it.

Moving Camellias (Kinglake).—Camellias can be readily shifted from a bed in the greenhouse if the operation is carefully carried out, but you are not at all likely to get plants of the size you mention into tubs 2 feet square, particularly after the roots have had free run in a bed of soil. It would, in all probability, be necessary to mutilate the roots considerably to get them into tubs of that size, with, perhaps, fatal results. As far as one can say without seeing the plants, tubs 3 feet square would be quite small enough. The autumn or early winter is a good time to carry out the removal, but in this case you must make up your mind to lose a season's flowering, and next to that period they may be shifted immediately the blossoms are over.

Furnishing conservatory (H. K.).—If the back wall is rough brick, good cement should suffice to fix the clinkers. The uppermost pockets should be 2 feet from the top of the wall. You could certainly arrange a shelf as suggested, but it appears to us that it would be very dark for any Orchid. The most likely to thrive there is *Cypripedium insigne*. Climbers may be planted in the spaces indicated, but in the temperate regions mentioned you will not get much life in the winter. *Clematis indivisa* is a good climbing plant for a greenhouse. The flowers are white and borne in spring. A Passion-flower, such as *Pasiflora Imperatrice Eugenie*, will do well for the opposite bed. The centre space may be occupied by a table-like stage, with the sides 2 feet 6 inches high, and the central position a step higher. Such a stage a local carpenter could easily erect for you.

Treatment of Clematises (An 11 Years Reader).—*Clematis Danubia* of Albany, which is one of the pretty hybrid forms raised from *Clematis cocinea*, needs very little pruning, all that is necessary being to cut out any very weak and exhausted shoots, while the principal ones may be cut back to a good eye. Your small plants of *Clematis Jackmanii* may be planted out at once if you do not intend to separate them, but if divided, which should be done now, it will be better to pot them and allow them to recover from the check of removal before planting out. The month of May will be a good time to do this. You may, if you desire it, grow the variety Mrs. George Jackman in a large pot or tub, and train it up the roof of the

greenhouse. This variety flowers early in the year from the old or ripened wood, so you must not cut it back yet. Any pruning required may be done immediately after flowering.

Aspidistra (Edwin).—It is not at all necessary to remove the *Aspidistra* flowers, as their weakening effects are very small indeed. Why one of the leaves of your plant turns yellow it is impossible to say with certainty, and we can only suggest two or three probable causes. The watering once a week may not be sufficient, though, generally speaking, it is ample, but unusual conditions may prevail that cause the soil to dry rapidly. Again, the reverse may be the case, as if the water is allowed to stand in the pan or saucer mischief will be caused. Gas, too, is very injurious to plant life in general, and your plant may have been exposed to the fumes thereof; if so, the mischief is readily accounted for. We have also seen a single leaf perish from taking a candle or lighted lamp in search of something close to the *Aspidistra*, and if either of these is held below the leaf for only a very short time, it will be greatly injured, if not actually killed.

Soil for aquatics (Knutsford).—We would first saturate the tubs with peat-moss, pouring in a quart or more, and painting the sides till it was absorbed. Now place a few shavings inside and set fire to them. Then turn the tubs upside down and so another fire. This will thoroughly char the inside, and destroy fungus, &c., in the wood. Pitch would be infinitely better than tar for painting the inside of the tubs, and it must be at boiling point when put on so as to run thinly. Six inches of soil will do quite well for *Nymphaea* and *Aponogeton*, and twice this for *Menyanthes*. If your refuse-heap is but the old potting soil of the past, this may be added freely; but not, we would not use it. The rain-water will be best if the other supply is very hard. Such water usually contains a large proportion of lime, which is injurious. The *Aponogeton*, for instance, rarely does much good in very hard water.

Scarlet Salvia (Amateur).—For keeping up a bright display in the conservatory from early autumn until Christmas the above are the best we have. Nothing would exceed in brilliancy the long racemes of crimson-scarlet, the tube and calyx being equally bright. Unfortunately, the flowers soon die, and are exposed to a change of temperature, therefore, they cannot be recommended for cutting and forcing, they are, therefore, not recommended. There is little difficulty in their culture. If a few plants are well cared for through the winter they will give plenty of cuttings early in the spring. Take the first cuttings as soon as they are ready, and these will give good strong cuttings later on. The best plants are obtained from the strong growing tops, which, if cut in about the end of May, will make fine plants by the autumn. By taking the tops of young plants it is easier to keep the plants free from red-spider, which is their greatest enemy. The plants may be grown on during the summer in a cool-frame or out-of-doors. Potted in a rich loamy compost and grown on without any stopping, they make fine pyramids if given plenty of room, and will come into flower early in September. If given sufficient pot-room and liquid-manure from time to time the same plants will continue to bloom for a long time.

Bedding arrangement (Box).—We would not mind you to adopt *Balsams* and *Potentillas* with a view to a successful bedding arrangement for July, August, and early September. The *Potentillas*, like the *Pentstemon* of a year ago, will give a flush of bloom in July, and occasional blooms at intervals. A more successful flowering plant would be *Ivy-leaved Pelargoniums*, pegged down light at first, and then, subject to the decaying flowers being removed, allowing the plant every freedom. Another suggestion is a groundwork of *Tufted Pansies* of some delicate colour, with *Balsams* freely distributed over all. These or *Zinnias* would do quite well. You do not give us the size of the bed, and our suggestion is necessarily restricted. Had you wished for a later and more continuous flowering we would unhesitatingly have recommended *Tufted Pansies*, planting good rooted cuttings quite early in July or before, and inserting *Tuberous Begonias* in between the middle of May or earlier. Or you may plant 3 inches deep, the *Begonias* in March, with mixed *Gладиoli* of the *Lemoinei* and *Childrei* sets, finally mixing the *Pansies* and *Begonias* in the bed when the other things are set. In this way you would have a bed as beautiful for a long time, while the bulbous plants would, if cared for, do just as well.

Palms and Ferns for greenhouses (A Country Reader).—Palms that will suit your purpose are: *Areca Baccata*, *Breca nana*, *Chamaerops excelsa*, *Chamaerops humilis*, *Cosca Weddelliana*, *Corypha australis*, *Heliconia Reimoserana*, *Kentia Forsteriana*, *Lantana borbonica*, *Phenix rupicola*, *Phorox tenuis*, and *Rhapiz distachyoides*. Ferns: *Adiantum cuneatum* (*Maidenhair*), *Adiantum decorum*, *Adiantum fulvum*, *Asplenium bulbiferum*, *Asplenium dimorphum*, *Blechnum occidentale*, *Cytosorus filicatum*, *Davallia bullata*, *Dicksonia antarctica*, *Polypodium aureum*, *Polystichum capense*, *Polystichum setosum*, *Pteris cretica*, *Pteris cretica albo-lineata*, *Pteris longifolia cristata*, *Pteris intermedia*, *Pteris serrulata*, *Pteris serrulata cristata*, *Pteris serrulata minima*, *Pteris setacea*, *Pteris plantaginea*, *Pteris Alcockii*, with leathery, Fig-like leaves and variegated variety; *Aracaceae excelsa*, *Aspidistra minima*, dark green, strap-shaped leaves, and clusters of terra-cotta-tinted blossoms now opening; *Cordyline* (*Dracena*) *australis*, *Cordyline rubra*, *Isolepis gracilis*, drooping tufts of dark green Grass-like leaves; *Ophiopogon Jaburum variegatum*, and *Ophiopogon spicatum argenteo-variegatum*, Grass-like plants, with white and yellow variegation respectively.

TREES AND SHRUBS.

Dead branches in Yew-trees (West Country).—The dead branches of the Yew should certainly be cut out, otherwise they will always be an eyesore. If, after removing the dead portions, there are any ugly gaps, this difficulty may be overcome by tying two or three of the neighbouring branches in such a way that they hide, or at all events, partially hide the defects.

Clipping Ivy (West Country).—It was quite right to clip the Ivy last spring, and we should say the ill-health owing to some other cause. You speak of it having been

measured. Was this overdone? It is difficult to say...

FRUIT.

Grafting wax (J. C. Bloomfield).—This everybody should keep on hand ready for use whenever needed...

VEGETABLES.

Celeriac (Morag).—If you allow your Celeriac plants to remain, no doubt they will all go to flower rather than their bulbs...

Lamb's Lettuce or Oorn salad (Morag).—In the case of Lamb's Lettuce or Corn salad the plants are usually sown...

Growing Spinach (Bastings).—Spinach is best sown in drills 10 inches or 12 inches apart...

Salt and carbonate of soda (R. J.).—Salt is a valuable ingredient to utilize partly as manure and partly as a retainer of moisture...

SHORT REPLIES.

La Cochin. See reply to Roma White re "Roses from the States," in our issue of Feb. 7, p. 653. Tulip.—Any smaller growing Perlis are the best for your purpose...

THE BEST PEAS

For Present Sowing

ARE SUTTON'S

Green Gem - Per quart, 3 6

Your Green Gem Pea has been wonderful. Sown in pots during February and planted out at the beginning of April...

A 1 - - - Per quart, 2 6

Your A 1 Pea is a wonderfully heavy cropper. I have never seen such Peas before combined with such good harvest...

80,000 NEW BOXES for SALE, suitable for Seeds or Potatoes; size, 14 x 8 1/2 x 2 1/2 inches, miles 1 inch thick; tied in bundles. Price 7s. 3d. per 100; if mailed together, 3d. per 100 extra.

EVERY TENANT HIS OWN LANDLORD. Send a post card mentioning this paper for further particulars to W. W. BENHAM, Esq., 12, Bishopsgate-street Without, London, E.C.

STRAWBERRY PLANTS.—Upwards of 50 of the best varieties now in cultivation. Sixteen plants for planting from 1s. Descriptive List, post free.—GEO. COOLING & SONS, Nurseriesmen, Bath.

GRAPES THE FIRST YEAR.—Extra strong fruiting canes of Black Hamburg, Alicante, Muscat of Alexandria, Gros Colman, and all other varieties which will bear several bunches the first season, at 7s. 6d. each; three for 21s. Descriptive List of Vines free.—GEO. COOLING & SONS, Nurseriesmen, Bath.

BEGONIAS, Prizo Strain.—Single, 1s. 2s.; Double, 1s. 6d., 2s. 6d. Cacti, 3s. 3d., 6s. 6d. Amaryllis, Glorinas, Tuleroses, 1s. 2s. doz. Gladiolus, 1s. 2s. 6s. L. Valley, 3s. 10s. 8 different garden Lilies for 1s., 2s., 3s., 4s., 5s., 6s., 7s., 8s., 9s., 10s., 11s., 12s., 13s., 14s., 15s., 16s., 17s., 18s., 19s., 20s., 21s., 22s., 23s., 24s., 25s., 26s., 27s., 28s., 29s., 30s., 31s., 32s., 33s., 34s., 35s., 36s., 37s., 38s., 39s., 40s., 41s., 42s., 43s., 44s., 45s., 46s., 47s., 48s., 49s., 50s.

ROSES.—H.P.'s and Teas of the best varieties for the seedling Brier at 6s. per doz. (six Teas and six H.P.'s), carriage free to any address for cash; good for planting. List of names on application.—HENRY NORTON, Rose Grower, Louth, Lincolnshire.

DICKSON'S CELEBRATED SEEDS should be sown by all who wish the Best Vegetables and the Cheapest Flowers. We will forward for five penny stamps a copy of our unique Catalogue, containing an expert's report of experiments, embracing upwards of 1,000 trials of seeds, and will present to each applicant a 6d. packet of Giant's Green Peas.—ALEX. DICKSON & SONS, Ltd., 61, Dawson street, Dublin.

CYPRIPEDIUMS.—Good vars., named, well-rooted plants, 6 vars., 6s.; 12 vars., 10s.; 15 vars., 20s., post free, cash.—ROGERS, Ludlow, Fezburgh, FORTIN'S GIANT and Jannoch's Giant Lilies of Valley, 5 best varieties, strong crowns, 5s., 6d.; 100 4s., post free, cash.—ROGERS, Ludlow, Fezburgh.

MALMAISON CARNATIONS A SPECIALITY. 12 grand varieties, distinct, for 3s.; 120 of each for 5s.—E. C. GOBLE, F.R.C.S., Walcot Nursery, Ryde, I.W.

TROPICOLUM TUBEROSUM.—Beautiful tricolor and orange cluster, easily grown, brilliant flowers all summer, 5 for 1s., free.—LANGTRY, Bryanston, Co. Down, Ireland.

RASPBERRIES.—Superlative (true), Yellow Antwerp, good canes, 6s. 100 car, paid; Gooseberries, Currants, strong, 2s. doz.—HILL, Ashton Gate, Bristol.

12 GRAND SINGLE PYTHRUMS, 3s. 6d. set, car, free: James Kelway, Albion, Beatrice Kelway, Queen of May, Princess Marie, Tasso, Mrs. Baleman Brown, Jubilee, David, Princess S. Graham, John H. Colby, Amelia, 12 CHOICE IRIS K. H. PERRY, 3s. 6d. set, car, free: Lord Roberts, Blenheim, Spotted Beauty, Emperor, Mahogany, Humboldt, Florist, Robert Craig, Edair, Ne'l Gwynne, Hong Kong, Hanis. Both sets, 6s. 6d., car, free, strong plants.—J. LANGFORD, The Nurseries, Winton, Manchester.

MILLIONS PLANTS.—Wallflowers, 5 best sorts, 1s. 6d. 100; Sovereign Strawberries, 1s. 6d. 100; Cabbages, 4 best sorts, and Lettuces, 1s. 100; all post free.—BOXHEDGE, Boxhedge Farm, Banbury.

LILIAM AURATUM (the splendid Golden-rayed Lily of Japan, white with gold stripes; very fine, large bulbs just arrived from Japan, 6 for 3s., 4d.; 12 for 6d., carriage paid.—C. R. SHILLING, Bulb Merchant, Winchfield, Hants.

SPECIAL.—6 Grand Tiger Lilies, and 6 Lilium speciosum, and 6 Pearl Tulips, splendid bulbs, for 3s. 6d., carriage paid.—C. R. SHILLING, Bulb Merchant, Winchfield, Hants.

AMPELOPSIS VEITCHII, true 3-year-old, 2s. 6d. doz.; A. 1s. 6d., Wisnara alba, 2s. 6d.; do. lina, 2s. 6d.; Burgonia radicans, scarlet, 4s. 6d.; Clematis gracilescens, yellow, 3s. 6d.; Variegated Vitis, Silver Queen, marginata, variegata, Rugosa, 6s. each. All free. Note address.—HENRY & CO., New road, Bourne End, Bucks.

PRODIGIOUS TOMATO, The Popular Favourite, unsurpassed for heavy cropping, enormous trusses of smooth fruit, finishing with slight point, no nasty eye. We grew three tons in our Nurseries last season, and received far better price for this variety than any other. Fruit deep rich colour, grand flavour, medium size, remarkable free setter. We are receiving daily testimonials from last year's delighted customers, with inquiries for seeds and plants. We can offer seed in 1s., 2s., and 2s. 6d. packets. Strong transplanted plants, 3s. doz., 50 for 6s., 100 for 9s.; pot plants, 4s. doz. Carriage paid. Full cultural directions free with orders. We can guarantee the above variety to be one of the earliest and most disease-resisting grown. Orders for plants booked now for delivery in March.

E. CAYE, 24, CARLTON NURSERIES, LOWESTOFT.

CHIVERS' "UNQUALIFIED PRAISE"

is given by the Family Doctor to Chivers' Gold Medal Jellies. It also says: "They are pure and free from any kind of adulteration." The Westminster Budget remarks: "Messrs. Chivers have a right to be proud of their Jellies."

SILVER-LINED PANS. Every possible precaution is taken in the preparation of Chivers' Jellies to ensure absolute purity. Home Notes describes the process as one of "exquisite cleanliness." They are flavoured with Ripe Fruit Juices.

CHIVERS & SONS, Ltd., Fruit Growers, HISTON, CAMBS.

J. DERRICK'S ROSES (Carriage Paid) Satisfaction Guaranteed.

25 Grand H.P. Roses: Rev. A. Cheales, Mad. Jonbert, 81/2 Gaiet, Wolsley, M. O. Jolignaux, Perfection des Blanches, Magna Charta, York and Lancaster, Jules Margottin, Mad. J. Perrier, C. Lasson, Mrs. John Laing, Louis Van Houtte, Merveille de Lyon, S. Vaizee, Countess of Oxford, B. Bonstetten, Marquise de Castellani, Abel Carriere, Duchesse de Bedford, Chas. Darwin, Rosee Johnson, Duke of Wellington, Mad. Gabriel Lunzet, Chas. Ledebvre, 6 for 3s.; 12 for 5s. 6d.; 25 for 10s. 6d.

12 Charming Tea Roses: Marie Van Houtte, R. Metz, I. Ideal, Helene Forester, Mad. Lambert, Francaise Kruger, Mad. Eugene Veidier, Etolie de Lyon, Laurette Mossy, Humete, Mad. Beuard, Bride, 6 for 4s.; 12 for 7s.

15 Superb Climbing Roses: Alance Vibert, Grimeson Lambert, Chednut Hybrid, Bouquet d'Or, Mad. Beuard, Nour. de Mad. Lambert, A. J. de la Gr., Réje d'Or, Reine Marie Henriette, Mad. A. Carriere, Devonensis, Reine O. de Wurtemberg, Glone de Dijon, Beauty of Knapton, La Marquise. Any 6 for 5s.; 12 for 10s.

12 Hybrid Tea Roses, 7s.; 6 for 4s.
 12 Mini Roses, 5s., 6 for 2s. 6d.
 4 Variegated Hies, Gold and Silver, 2s. 3d.
 6 Moss Roses: Laven, Crested, Pink, Striped, etc., 3s.
 6 Japanese Roses: Rugosa, Mad. G. Briant, etc., 3s.
 6 Anemone Buds, yellowest of all Roses, 3s. 3d.
 6 Anemone Veitchii, self coloring, 2 & 3 year plants, 2s. 6d.
 6 Fine Awarded Climbing Shiraz and Claret, 2s. 6d.; 12, 5s.

BEGONIAS.

Ware's Famous Strain. Tubers, single, mixed for bedding, 2s. 6d. per doz., 18s. per 100; in 12 colours, for superior bedding or pots, 4s. to 10s. per doz., 25s. to 70s. per 100. Double, mixed for bedding, 4s. per doz., 30s. per 100; in 12 colours, for pots, mixed bedding, 7s. 6d. and 9s. per doz., 55s. and 70s. per 100. Gems for exhibition, 32s., 35s., and 35s. per doz. (Single named varieties of single and double free Catalogue). Seed, saved from our celebrated Exhibition Collection, single, choice mixed, 1s. and 2s. 6d. pkt. Double, choice mixed, the best obtainable, 2s. 6d. and 5s. per pkt.

THOS. S. WARE (1902), LTD., FELTHAM.

FORBES' ILLUSTRATED CATALOGUE

(172 PAGES)

CONTAINS THE BEST EXISTING COLLECTIONS OF ALL FLORISTS' FLOWERS & HARDY PLANTS,

Including his world-renowned "GOLD MEDAL FENSTREMONS, FALUKES, &c." With carefully revised Descriptions, Cultural Directions, Colour, Height, Time of Flowering, British or common Names, Price, &c., &c.

Exports unanimously accord "FORBES' CATALOGUE" the unique and conspicuous distinction of being the best and most probably accurate Up-to-date Reference Book extant.

IT IS FREE ON APPLICATION.

JOHN FORBES, NURSERYMAN, NAWICK, SCOTLAND

TEA ROSES—BEST VARIETIES.

In 5 and 6-inch pots, 1s. 6d. each; in 7 and 9-inch pots, 2s. 6d. and 3s. 6d.

MARECHAL NIEL, extra strong for greenhouse, 3s., 6s. and 5s.

VINES, strong planting Cases. Black Hamburgh and other leading varieties, 4s. and 5s. each.

CARAWAY & CO., Durdham Down Nurseries, BRISTOL.

PROTECT YOUR GARDENS.

Nothing, small mesh, will keep off the smallest birds, 35 square yards for 1s. Will not rot if left out in all weathers. Sent any width. Carriage paid on all orders over 5s. As supplied to the Royal Gardens. Cash returned if not approved of.—H. J. GASSON, Garden Net Works, Ltd.

SHILLING'S SEEDS

are the best for Amateurs and Gardeners. Specimen Testimonial just received from:—
 G. Miller, Esq., Ship Mill House, Swanhill, Kent. Jan. 5th, 1903. "I do well with your seeds at this time last year took 12 First Prizes, 8 Second, and 8 Third with a 14th prize from your seed."

SWEET PEAS.—Any of the following splendid kinds supplied in packets at Two-pence each, each packet containing 100 Seeds and over: Sage Burpee, Salopian, Lady Bristol Hamilton, Countess Coligan, George Gordon, Blanche Burpee, Turquoise, Navy Blue, Mars, Red, Dugdale, Lady Mary Currie, Emily Henderson, Prince of Wales, Lovely, Countess of Powis, Aurora, etc. Kindly note.—All the latest and best Sweet Peas in Packets at Two-pence each, and containing 100 Seeds in a Packet.

ASTERS.—Unsurpassable strains of the highest excellence. All Two-pence per Packet, such as Bull of Jewel Aster, Victoria, Chrysanthemum lowered, Comet, Mignon, Peony-Bowered, Perfection, Triumph, Beutende's Quilted, etc.

TEN-WEEK STOCKS, Marigold, Balsam, Zinnias, Phlox Drummondii, in 24 Packets, and a trial against any strain in the Kingdom is solicited.

TWO-PENCE PER PACKET.—Flower Seeds of the highest excellence. Note! all over the Kingdom, such as Begonia, Calceolaria, Carnation, Clematis, Lobelia, Cockscomb, Heliotrope, Pansy, Petunia, Primula, Teasma Sunbird, etc., etc.

TOMATOES.—Best kinds, 2d. and 6d. per Packet. Shilling's King, Winter Beauty, Endive, Unto Day, Holmes Supreme, Sutton's Perfection, Golden Nugget, The Peach, etc.

CUCUMBERS.—Best kinds in 6d. Packets.—The Rochester, Shilling's Amateurs' Own, Telegraph, Lockie's Perfection, Sutton's Cluster, All-the-Year-Round, &c.

ONION.—Selected Ailsa Craig, very special and select stock for exhibition. Seed guaranteed to be saved from Onions weighing 3lb. to 4lb. each. 6d. and 1s. per Packet.

SUPPLYING the Cheapest Seeds in Economical Packets has been our speciality for years. Catalogue containing particulars of every seed you require for your garden, with a sample Packet, post free. Will send any of the above mentioned Seeds post free on receipt of remittance.

C. R. SHILLING, Seed Merchant.

WINCHFIELD, HANTS.

"MARVELLOUS VALUE, BOTH FOR QUANTITY AND QUALITY," is what everyone says about SHILLING'S

NALF-CROWN COLLECTION OF SEEDS.
 It contains 16 kinds of Vegetable Seeds, including Peas, Beans, Onion, Cucumbers, Cauliflowers, Tomato, and 10 others, and 100 page Gardening Guide. The Cheapest and best 2s. 6d. Collection of High class Vegetable Seeds ever offered. Post free, 2s. 6d.

C. R. SHILLING, SEEDSMAN, WINCHFIELD, HANTS.

EXHIBITION SWEET PEAS.

The "CESTRIAN" Collection.
 20 Named Sorts (1,000 Seeds). 2s. 6d. Free.
 The Best and most Liberal Selection ever offered.

Coccolina , new scarlet Satopian, deep crimson	Lady G. Hamilton , helio trope
Gen. Gordon , rich crimson	Black Knight , rich mignon
Prince Ed. of York , scarlet and rose	Othello , deepest maroon
Miss Willmott , coral-pink	Duke of Westminster , rose violet
Gorgeous , rich deep orange	Navy Blue , dark blue
Prince of Wales , deep rose	Blanche Burpee , giant white
Prima Donna , pink	Sadie Burpee , pearl white
Lottie Hutchins , creamy-pink	Hon. Mrs. E. Kenyon , yellow
Dorothy Tennant , rosy mauve	Lady M. O. Goro , apricot
	America , red striped

Our Customers last year won First Prizes all over the country with the above varieties.

ARMITAGE BROS., LTD., High Street, NOTTINGHAM.

GARDEN GUIDE FOR 1903 IS NOW READY.

EVERY YEAR this valuable publication is eagerly sought after by Amateur Gardeners and others who are interested in gardening. The usual number of pages is increased number to cultural hints, which have been specially prepared and brought up to date by including reports. In addition to cultural notes, the Guide contains a fully illustrated and descriptive price list of Vegetable and Flower Seeds, Florists' Flowers, Ferns, Shrub, and in fact, everything for the Garden. The price is 1s., but for a short time we are prepared to send this "Garden Guide" gratis to Amateur Gardeners' Handbook—free for actual cost of postage—3d.

Some Examples of the BARGAINS contained in GARDEN GUIDE:

HOBBIE'S GIANT SWEET PEAS.
 Our Giant Sweet Peas were awarded the Gold Medal by the N.S.P. Society in July last, being the second time in over five years. We send ten packets each of about 30 lbs. (about 500) in all free for 1s. 2d. each. Navy Blue, Sage Burpee, Countess of Lathom, Gorgeous, Firely, Lady Goro Ham 10/1, Black Knight, Chancellors, Countess Coligan, Prince of Wales.

Collection "B"—Six varieties, all introduced in the year about 1870, seeds in each packet, 1s. 2d. each. Coccolina, Hon. Mrs. E. Kenyon, Miss Willmott, Lady Goro, Goro, George Gordon, and Mount Blanc. The two Collections, as above, free, for 3s. each.

Dorothy Eckford.—Our white sport from Mrs. W. Eckford, for which we obtained four F.C.C.'s and the A.C.C. of the R.H.S. last year. Per packet, 1s. 2d. (ten seeds)

12 TEA ROSES, free, for 6s. 6d. each.—These are: Madame Curie, Fannie des Jardins, Anna Hervey, De Nabonnand, Paps Gontier, Mme. Beuard, Soue de Calver-Guillet, G. Nabonnand, Marie Van Houtte, Etolie de Lyon, Docteur Grill, and Marie d'Orleans.

For other COLLECTIONS see GARDEN GUIDE.

HOBBIES LIMITED
 (with which is incorporated JOHN GREEN, ISSI) Norfolk Nurseries, DEBBEHAM.

£1,000 OFFERED IN CASH.

Prizes at Every Horticultural Show.

181 First Prizes Won by Mr. O. Pilling, Elland in 1903 with our Seeds.

DIRECT FROM THE CROWERS SWEET PEAS

BEING one of the largest (bond-fide) English Growers, and having grown about 10 acres of the finest varieties, we picked out the best of each color, making 20 distinct varieties. (Notes of our fields appeared in the gardening papers.)

100 Seeds of each, 5s. 6d.; 50 Seeds of each, 3s. 6d.

Blue (deep), Navy Blue	Pink and White, Triumph
Blue (high), Emily Eckford	Yellow, Hon. Mrs. Kenyon
Blue and White, Maid of Honn	Purple, Mrs. Kenyon
Blush, Duchess of Sutherland	Rose, Prince of Wales
Crimson, Mars	Rose (shaded), Mrs. Dugdale
Indigo, Duke of Clarence	Rose-scarlet, Coccolina
Lavender, Lady G. Hamilton	Salmon, Venus
Lilac, Lady Schomersdale	Striped Blue, Princess of Wales
Magenta, Captivation	Striped Red, Mrs. J. Chancellors
Maroon, Othello	Striped Red (deep), America
Mauve, Duke of Westminster	White, Sadie Burpee
Mauve (delicate), Lady Nina Balfour	
Orange, Lady M. Currie	
Orange-pink, Miss Willmott	
Salmon, Gorgeous	
Pink, Lerely	

Above are the best of each color.

12 CHOICEST VARIETIES.
 Miss Willmott, orange pink; Hon. Mrs. Kenyon, yellow; Lady G. Hamilton, lavender; Othello, maroon; Lottie Hutchins, buff; Duke of Westminster, mauve; Gorgeous, rose-scarlet; Duchess of Westminster, salmon; Sage Burpee, white; Navy Blue, blue; Mrs. J. Chancellors, striped; Miss Dugdale, rose. Post free, 2s. 6d.

VEGETABLES.

SEED POTATOES.

ALTHOUGH we are having a comparatively open winter, it is satisfactory to find seed Potatoes are keeping well. When in past seasons we had hot, dry summers, which ripened the tubers very early, and left them often immature, the past summer being both moister and cooler, evidently so far as reproductiveness is concerned, created more sappy tubers, and less disposed to dry or shrivel, also less ripened. The result is now seen in tubers that are fully exposed to light and air, even in a temperature of 45 degs., keeping fairly dormant. In past winters I have had the tubers bearing shoots several weeks earlier, thus giving material trouble to keep restful. When shoots are thus early formed also, they are usually weaker than are those from which more sappy tubers grow later. It must not be assumed that tubers having more rather than less sap or water in them are less fitted for seed than are those fuller of starch granules. A dry tuber lacks capacity to throw stout, hard shoots; a sappy tuber not only does so later, but can produce stouter shoots. I deduce from the present condition of Potato tubers as kept well exposed to light and air for ultimate planting, that we shall see next May or June far less of those bare patches such as marked the Potato breadths of last year, allied to which it is hoped may be much more robust growth. Should that be so, it will be something to be thankful for to a cool, wet summer, for the Potato stocks thus planted will recuperate and again show evidences of normal strength and productiveness.

Generally those who plant Potatoes do so far too early. They forget that although the stock of this exotic has been with us 300 years it has gained nothing in hardiness. Planting the tubers in cold soil in March may do the tuber itself little appreciable harm, but it does militate greatly against the production of robust shoots, as the blanched ones yet in darkness in the soil are very tender, and do naturally suffer because of the lack of warmth such tender products need. Even when the shoots have forced their way through the cold soil into daylight, and have begun to form leafage, they have to face white frosts, which to them are most destructive, and if but once thus injured the plants never again become strong or are so tuber productive. If seed tubers be now placed in shallow boxes, with their eye or bud ends upward, set close together, then kept in ample light and air, yet free from frost, they will push one or two stout, firm shoots or sprouts, and these in light will not exceed an inch in length. Then if kept so stored till the end of April, by which time the soil will probably have become several degrees warmer than it was in March, and when growth does follow, as it will from these sprouted tubers quite rapidly, the tops will escape harm from frost, and thus ensure that the plants will, uninjured, be enabled to produce in the autumn liberal crops of tubers. On

warm borders, where it is possible to furnish some shelter for the tender tops on frosty nights in the spring, it is safe to plant some early variety even at the end of February, but that should be done only on south borders that are well sheltered and where the soil has been slightly warmed by having a dressing of half-heated stable manure dug in as the planting proceeds. For main crops it is much the wisest to have ground for them trenched, the manure dressing being buried down in the subsoil. That helps to impart some warmth to it, and later induces the roots of the Potato plants to go deep. A dressing of potash and superphosphate, mixed and well crushed, put on the ground and forked in on the surface a few weeks before planting is done, does great good. Planting should be in rows of good average width—that is, according to strength of tops—from 30 inches to 36 inches apart, the tubers from 14 inches to 16 inches apart in the rows, and buried just about 4 inches under the soil, which should before covering be well broken and pulverised, so as to lie light on the sets.

VEITCH'S SELF-PROTECTING BROCCOLI.

ONE of the most valuable—indeed, a most indispensable Broccoli is Veitch's Self-protecting Autumn, and no seed order would be complete that did not include it. Since its introduction, now a good many years ago, others similar have come to light, but a good selection of the original still remains without a rival for the late autumn and early winter months. Its hardiness is wonderful. Only this past season, after a spell of severe frost and cold, cutting winds, I came across heads undamaged and pure in colour, much to my surprise, and which proved the more useful because unexpected. To get a supply over a long season more than one sowing is needful; not that a succession is denied those who depend on one sowing. It is, however, not from one solitary sowing that one is furnished with heads over a good portion of the winter. It is necessary to carefully select your stock, for there are good and inferior strains in commerce, though not, perhaps, in this more than in other kinds. The Self-protecting, sown at the same time as the Autumn Giant, forms a connecting link in the season of Cauliflowers and Broccolis, and when this is past there are few really reliable varieties that can follow on for kitchen use for a time. Should the weather be normal it is not difficult to have a supply quite up to Christmas, and should the stock of plants hold out and the weather remain favourable heads may be had during January. Its same supplies the secret of its hardiness, for as matter how good a Broccoli may be as regards growth and quality, unless the flower is protected with eafolding leaves it quickly falls a victim to severe or even moderate frosts. In some kinds, as soon as frost touches them the leaves fall away and expose the flower to the weather. It need not be said that these are the first to succumb. During the season I sow at intervals in March until June small batches of Self-protecting, and by these means get

though not perhaps large, heads in daily succession from October until Christmas, if not later.

W. S.

NOTES AND REPLIES.

Garden soil.—I shall be much obliged if you will advise me what to do with a piece of ground, a specimen of the soil of which I enclose? It slopes south and east, and is fully exposed to the sun, and sheltered from the north and north-east winds by a wall. For the last two years, during which time it has been dug and manured after each crop, nothing has grown well—Carrots, Spinach, and Potatoes were failures. The last dressing was good old farmyard manure, the one before not very old, loam stable. I wanted it trenched last year, but my gardener said it was unnecessary, as the soil was so sandy and porous. It has not been trenched for at least seven years. The subsoil is good in the rest of the garden, and it all yields good crops. I shall be grateful for an answer as soon as your space will allow.—I. W. W.

[The sample of soil sent shows it to be of a loamymarl, porous when dry, and apt to become sticky when wet, when, of course, it should not be worked. We expect you have beneath a deep chalk base. Why your gardener should object to trench the ground, breaking up the subsoil well, other 10 inches to 12 inches, we cannot understand, as trenching is one of the most important factors in vegetable culture. Probably you bury your manure too shallow, whereas, to encourage roots to go deep, especially in the summer, when the weather is hot and dry, manure should be mixed with the subsoil in the trenching. It is very probable that this year your soil would benefit by an application, dug or forked in at once, of superphosphate and kainit, at the rate of 5 lb. per rod, in equal portions, and adding a dressing of sulphate of ammonia, 3 lb. per rod, over the surface after crop growth has begun. Your subsoil may be porous, but it needs breaking up, airtight, and manuring for the good of the crops.]

Temperatures for Mushrooms.—Now that we have got into what is generally the coldest period of the year, Mushroom beds will not keep in bearing unless a genial and equable temperature can be maintained within the structure. Where a regular supply of Mushrooms is looked for and no attempt is made to keep up a genial warmth, the supply will naturally fall off suddenly. The beds may not be spoiled and they may even bear again when a genial time arrives for their so doing, but a growing temperature must be maintained if Mushrooms are to be secured. For this reason, if the temperature can be maintained at 55 degs. or a few degrees lower in a very cold weather, there need be but little fear of the Mushrooms failing—that is, other conditions being right. Very often a growing temperature may be maintained by the aid of fermenting material, a heap of this being placed within the structure and turned occasionally, the ammonia which is given off being very beneficial. In unheated sheds and sae-like places where beds are made up, the temperature must be kept up by coverings of dry litter or hay. If it becomes damp through contact with the bed, it should be turned occasionally, placing the drier outer covering against the bed. If this is not done, the spawn is apt to be drawn through into the damp

GARDEN WORK.

Conservatory.—Bulbs of *Lilium Harrisii* that were potted early will now be coming forward, even where only moderately forced. If some use is made of retarded bulbs, one need never be without white *Lilium* now, and the flowers are almost indispensable for wreath making and other decorative work. *Lucaulia gratissima*, which has done flowering, may be pruned back. If grown as bushes in the borders the plants may be cut rather hard back, but when trained to a wall the pruning may be less severe, as the young shoots may be trained in if there is a wall surface to cover. Strong-growing climbers, such as *Tacsonias* and *Passion-flowers*, are breaking into growth, and the young shoots should be thinned, and those left trained in. *Heliotropes* planted in the border should be pruned in more or less, according to the space to be covered. Young plants of *Heliotropes* for early flowering in pots should be shifted on and helped in a warm-house near the glass. Sometimes young plants are selected now and trained as standards for summer flowering. Some of the newer varieties have very large flowers. Lord Roberts has very fine flowers, and *Queen of Whites* is a good companion to it. Cuttings rooted now and grown freely in heat will make fine plants by June. The early-flowering white *Marguerites* are useful, and will soon be coming into bloom. Forget-me-nots and white *Pinks* gently forced are charming for grouping round the margins of the stages or borders, and the flowers are useful for filling small glasses in the drawing-room or on the dining table. The temperature that will suit plants from the forcing-house will not be much under 50 degs. at night. Cuttings of *Tree-Carnations* will strike now in sandy soil in heat. They may be rooted in pens of damp sand very rapidly if the pans are placed over a flue or hot-water pipe, so that the temperature remains constant. The conditions as to moisture must also be equable. Shift herbaceous *Calceolarias* into flowering pots and grow cool, but safe from frost. *Cinerarias* are very useful now, and are among the cheapest things we have, and may easily be made into large specimens by giving plenty of pot room and good soil. When well grown, the green-fly is not so troublesome. Freer use may now be made of liquid-manure in a weak state. Soot-water, when clear, is good for most things.

Stove.—Such summer-flowering bulbs as *Gloxinias* and *Achimenes* may now be started in brisk heat, and seeds of the former may be sown. Seedlings from a good strain produce very fine flowers, and there is more vigour in seedlings than in plants raised from cuttings. The propagation of *Gloxinias* from cuttings can be carried on by taking off the leaves and inserting the leaf-stalk in sandy peat in a warm pit, or the leaves may be laid on pans filled with sandy peat. The midribs of the leaves are severed in several places, and the leaves at these points held down securely on the sand by means of small wire pegs. Bulbs will form where the leaves have been cut, and rest upon the sand, and this is an easy way of working up stock from named varieties. *Begonias* may be rooted from leaf cuttings in a similar manner. A further instalment of *Peel Tuberoses* should be potted and brought forward in heat as required. The dwarf forms of *Cannas*, now so much grown both in the conservatory and outside, may be divided and brought on in heat for early flowering. When some growth has been made they can be moved to a cooler house. Seeds of *Palms* of various kinds may be started now either in pots or boxes, or they will grow if laid on the surface of the propagating bed. They can be potted up when they start into growth.

Orchard-house.—The buds are swelling fast now, and it will be best, unless the weather is very mild, to give all the ventilation from the roof of the house, and not open the front lights till the weather gets quite mild. Harm has been done by permitting a cold rush of air through the trees just as the flower-buds are bursting and the young growth showing the green points of the leaves. More water will be required now, as the roots are active, and must be supported. Do not crowd the trees. Let each have space enough for the roots to circulate freely. When the blossoms open, the

stem of each tree every day when the pollen is dry with a padded stick to distribute the pollen. There is not much difficulty in setting the fruit at this season. Disbudding should be done in a tentative way and spread over several weeks, and the same course should be followed in thinning the fruit.

Late vinery.—In the usual course, late Vines, such as *Gros Colman*, *Alicante*, and *Lady Downes*, will break in March, and it is as well to use a little fire and hasten the start a little, as it will be better to do more of the work at this end of the season and not have to fire up at the end of the summer or autumn to ripen the fruit. *Muscats* must have fire-heat if they are to finish properly, and the start should be made at once. Of course, Vines started now will not require so much fire-heat as those started two months earlier, and 50 degs. will be high enough to start with, and to keep up this temperature, or even more, very little fire-heat will be required. At this season, in mild weather, the thermometer often stands above 50 degs. at night without fire. It is during the cold, damp weather that fire-heat is wanted.

Tomatoes.—In the early house the plants have now made considerable growth, and the first trusses of blossoms are appearing. The first crop, anyway, should be grown in pots, and there will be time enough to fill the house again with the second lot of plants to come in later, so as to succeed the open-air crop and bear through the autumn and winter. If a house can be given up to Tomatoes, two crops should be produced in any season to make them pay.

Window gardening.—A few pots of *Forget-me-not* can be brought on in the cold frames through the winter, and moved to the window now with *Snowdrops*, *Crocuses*, and *Narcissus*. *Canterbury Bells* will come later. The various forms of hardy *Primulas* are lovely in the window now. Among tender plants *Cinerarias* are bright and effective. The only trouble with them is to keep down green-fly. If they cannot be smoked or vaporised turn the plants upside down and dust a little Tobacco-powder among the leaves.

Outdoor garden.—Beds intended for choice *Carnations* should have the last turn over with the fork. A sprinkling of soot just previous to forking will be useful. Fresh leam, if obtainable, is a better dressing than manure. I am assuming the soil in the beds is not poor. Disease often attacks the over-manured plants. Hybrid *Columbines* are lovely things in the borders. Those who have no stock may sow seeds now in a little warmth, and grow on under glass till strong and then plant out in groups. Those who want bright, cheap masses of flowers in beds and borders may sow *Antirrhinums* in heat now. Prick off into boxes when large enough, and plant out, when sufficiently hardened by exposure, in cold-frames. Great improvement has been effected in these plants of late years. The self colours are best for general effect, and if the seeds are carefully saved the seedlings come fairly true. *Dahlias* may be started in heat and seeds sown to raise new varieties. Finish planting late-flowering *Lilies* and prepare beds for *Ranunculus*. These have been neglected of late years, but they make lovely masses. Like all the *Buttercup* family they want moisture, and to meet this need place a layer of cow-manure, about 10 inches or so in depth, in the bed. When the beds are ready draw drills 8 inches apart and 2 inches deep, and plant the bulbs, claws downward, 5 inches or so apart. All kinds of planting may be done now. When planting now and onwards settle the soil round the roots with water.

Fruit garden.—Morello Cherries and cooking Plums are the most profitable fruits to plant on the north walls, and the spaces between the trees may be filled with *Red* and *White Currants*. To grow good *Figs* away from the south coast the roots must be kept within reach. This can be done either by planting on a bed of concrete or by placing from 9 inches to a foot of brickbats or clinkers and grouting them in with lime, which will be cheaper than concrete. This foundation under each tree should be 5 feet square, and at any future time the trees make too much growth the roots which have passed the edge of the

foundation can easily be lifted and shortened. The same course can be adopted with *Peaches* and *Apricots* where the subsoil is clay. The depth at which the foundation is placed must depend upon the character of the subsoil, drainage, etc. But when the soil is bad the roots can easily be kept out of it, and the cost need not be excessive. Those who are thinking of planting open-air *Grapes* might adopt the same course with advantage. All pruning and training should be completed as soon as possible, as the buds are swelling. It is difficult to give an opinion upon next year's fruit prospects. The wood in many places was badly ripened, and blooms will set badly, if at all.

Vegetable garden.—There is one piece of advice which may be given with advantage now, and that is: Do not tread on the land when it is wet. If seeds have to be sown on the early borders, and the sower cannot wait, let him use a board and move it along as the work proceeds. This is a very old plan when planting out small plants, such as *Lettuces*, and for sowing small seeds on damp land. In most gardens the seeds for many crops will remain a little longer in the seed bags, unless the weather should compel us to come out and sow. Onions may be sown towards the end of the month, but if anyone wants big Onions he will have sown the seeds in a box, and they will now be on a shelf in the greenhouse gathering strength ready for planting out in April. Parsnips may be sown now, and *Salsify* shortly. Plant out *Seakale* cuttings in rows 15 inches apart and 12 inches from each other. The land both for this crop and *Asparagus* should be deep and in good heart. Soil forms a good dressing for both plants, and may be used at the rate of 1 lb. per square yard and forked in. I like to plant *Asparagus* when the growth is just moving, which is not before the end of March or beginning of April, and if plants have to be purchased, get them as near home as possible and plant on arrival, but it is best to raise *Asparagus* plants at home. Seeds may be sown now. E. HODGKIN.

THE COMING WEEK'S WORK.

Extracts from a Garden Diary.

February 23rd.—Sowed more Peas, including early and second early kinds. There are never too many early Peas. Longpod Beans have also been freely planted, as the latter crops, as a rule, are not equal to the early ones. The hoe is used freely among the rows of *Spinach*, *Winter Onions*, *Lettuces*, and *Cabbages*. More of the two last have been set out from the seed-beds, and seeds have been sown both under glass and outside, too, for succession. Took up the last of the *Jerusalem Artichokes* and selected sets for planting.

February 24th.—Covered rows of *Seakale* outside with sandy soil for blanching 1 foot deep in a ridge shape. One *Asparagus* bed has been covered with spare lights to forward the growth. This comes in between the forcing-bed and the unprotected crop-beds outside. Sowed *Tomatoes* for planting in cool-houses and on south walls outside. The *Grapes* in earliest houses are now being thinned. These are *Hamburgh* and *Foster's Seedling*. *Spinach* is sown as a catch crop between rows of Peas.

February 25th.—Lawns and walks are rolled as often as is necessary to maintain an even surface, generally after rain or frost, when the surface requires pressure. Finished washing fruit-trees with an insecticide. We find this useful in reducing insect enemies. Wall climbers have been pruned and tied in and thoroughly soaked with an insecticide.

February 26th.—Pruned Ivy on buildings, and where need as edgings or to cover ground under trees the same treatment is given to ensure a close, green growth all through the summer. Some evergreens that had become too large for the position have been cut rather hard back, and a few old *Laurels* have been grubbed up to make room for *Hollies*. Planted more early *Potatoes*. A little warm earth has been placed round *Potatoes* in frames.

February 27th.—The conservatory has been rearranged, and the places of faded plants filled with others just expanding their flowers. Groups of *Hyacinths* and *Narcissus* are very

conspicuous. Hyacinths are arranged in groups of one colour. Lilacs are very useful now, and are easily forced when established in pots. Japanese and Indian Azaleas and the old Azalea pontica, being so sweet, are all effective. Of course, as fast as one batch leaves the forcing-house another takes its place.

February 25th.—Propagating in most of its forms is continually going on. A good deal of the work that was formerly done in pots is now done in shallow boxes. All such plants as Alternanthera, Colens, Iresine, etc., required for hedding do well in boxes, and it saves space. We have commenced repotting our collection of stove plants, and suitable cuttings are taken when required to keep up stock. Most things will root freely during the next two months if kept close in a brisk bottom-heat.

FRUIT.

APPLE BELLE DU BOIS.

This, one of our best cooking Apples, is often grown under the names of Gloria Mundi and

planted 3 feet apart in fairly good ground, and may so remain for two years. After planted now, though best a few weeks later, the single shoots or stems on each maiden should be cut back to some 9 inches from the bud insertion. They will form probably three or four shoots from each stem, and those should be encouraged by giving liberal waterings and a mulebing of manure over the roots in the summer to make strong growth. The following year these shoots may be in turn hard cut back to, say, 12 inches length of branch, and each one breaking into two or three shoots will thus practically lay the sure foundation of a proper bush-tree. Early that winter the trees, then well worth 2s. each, will need to be lifted and replanted in entirely fresh soil; indeed, now they will be ready to furnish the ground they are intended to permanently occupy. But, being yet so small, the trees may be planted in rows 12 feet apart, and the trees in the rows 6 feet apart. So planted and more moderately pruned each year they can all remain for two years, the intermediate ground being otherwise cropped. Then, if other ground be ready, every other tree can be lifted

young trees have evidenced. That shows how well frequent transplanting tends to create what all fruit growers need—early fruitfulness in their trees. A. D.

NOTES AND REPLIES.

Suckers from Plums.—I had a quantity of suckers from an old Victoria Plum-tree given me about a month ago, which I straightway planted. The average size of them is about 26 inches high, and of good, stout growth. Will these be suitable for budding this coming season? Should they be cut down before budding or after, and could they be grafted the following season if budding failed this season?—S. W.

[These should be fit for budding next July, provided they go on satisfactorily. See that they do not suffer from the want of water later on, should the weather set in hot and dry during May and June. Cut back the growths to within 6 inches of the ground, a little before budding takes place. Should the buds fail, the stocks may be grafted next spring. Why not head down now at once, and graft this spring as soon as the sap is well on the move, so as to gain time, the Plum doing equally as well when grafted as when budded?]

Treating Strawberry-bed.—I made a bed of young Strawberry plants about a year ago, and put a great deal of manure into the bed at the time. I gave none since then, but during the summer time and autumn I covered the beds with dry straw from the manure heap. It is still on them, and looks very wet, kindly tell me should it now be taken off, and if this is the proper time to dig in fresh manure between the lines, and when should straw again be put on the beds?—G. M. N.

[Provided your straw dressing applied to your Strawberry bed last summer did not cover the plants, but allowed the leaves to be fully exposed to light and air, no harm was done, and perhaps some good. But leaving it amongst the plants now can only result in causing the soil to be wet and cold. Remove it at once, let the soil dry a little, then to allow air to penetrate, with a fork just point over the surface from 2 inches to 3 inches in depth to sweeten it, but do not dig, by any means, as that would harm the roots greatly. The plants cannot now need more manure as you seem to have dressed them very liberally. So soon as the plants have bloomed, lay them out carefully under the leaves and trusses of forming fruit some clean straw or dry straw-litter just to keep the fruit from the soil and clean. After gathering the fruit and clearing off all runners in the summer, then you may apply a dressing of manure to be washed in.]

Winter pruning.—Now is the time to get on with this important work, for although most cultivators have different ideas as to the extent to which pruning should be carried, few would go so far as to say that it can be dispensed with altogether. The first thing to do in pruning is to begin in the centre and clear out all useless spurs and cross-pieces, so that the light and air can penetrate right into the centre, then thin out any pieces that seem to be overcrowding their neighbours and shorten the leading annual growths to about half their length. Any that are required for forming new fruiting spurs must be shortened to three or four buds. Of course, this refers to bearing trees. Younger trees that are forming heads must have the leading growths left two-thirds of their length, so that they may form the main branches of the tree. The grower should know the habit and peculiar growth of each kind and regulate the pruning accordingly, as some kinds fruit on the tips of the young wood better than on spurs.—J. G., Gosport.

Bush fruit planting.—When carrying out the annual planting operations the bush fruits should not be overlooked or neglected. Undoubtedly October and November are the best months for this work, but all are not able to get through the work so early, and very little if any difference will be seen ultimately in bushes planted early or late in the winter so long as mild and open weather is chosen for the work. Currant and Gooseberry bushes are often kept cumbering the ground for years after they have passed their prime, and the same remark applies, in perhaps a less degree, to Raspberries. No doubt this is often the result of having no available young bushes to take the place of the old ones, but cuttings are so easily struck and brought on to bearing size that this should be no excuse. There may be a slight lessening of the bulk of fruit from young bushes, but the fruit will be much finer and more satisfactory. Wholesale clearance of

Apple Belle du Bois (syn. Gloria Mundi, Baltimore).

Baltimore. As our illustration shows, it is a very fine fruit, and used to do well at Chiswick when grown on the Paradise stock. It is a favourite Apple with exhibitors, owing to its large size, its season being from October to Christmas. Belle du Bois is a large, pale green fruit with flattened base, angular, sometimes oblong, flesh firm, with a somewhat acid flavour. It is best used early in the season, as it soon loses its briskness. Many object to it as being a shy bearer, which in some soils is true when worked on the Crab, but on the Paradise we have never found it fail. Grown in bush or pyramid form it makes a handsome tree, but the bush is the better, as the fruit can be more easily thinned in this way, and no one will regret having a tree of this Apple in bush form in the garden.

BUSH FRUIT-TREES.

If anyone not too advanced in years wishes to embark in the culture of hush fruits—Apples especially—and wants to obtain trees fairly cheap, he can hardly do better than purchase maidens suitable for making bush trees, worked on the Paradise stock, which may be had from 9s. to 10s. per dozen. Those can be

and be replanted, still in rows 12 feet apart, and each tree 12 feet from the other in the row. The check thus given will prove very advantageous in inducing the young trees to carry fruit, and, in the case of the latest transplanted, it is probable that gross root or wood growth never would result. Of the trees left, should some seem to be too gross, it will be wise to lift them carefully and replant them, as they, too, will greatly benefit by the check. When very young trees, and especially maidens but one year from the bud, are planted permanently, they are apt to become too deep-rooted for fruit production.

It may be said that all that has been advised means considerable labour. That may be so, but it has, on the other hand, two important compensations. First, the plan advised recognises the fact that economy in the use of land, which in the interim may be producing other and profitable crops, is important until the trees become productive. The second is, that the transplanting not only saves great waste of labour later in root-pruning big trees, but tends to induce earlier fruiting, and thus the extra cost for labour is well repaid. I have often noticed in nurseries the result of the precocity of fruiting yearly moved

plots may not be wise, but a row or two at least could be destroyed yearly. Very old stools of Raspberries get their roots matted together, this and the dead remains of previous growth making good progress impossible. As plantations are made to last a few years, the ground should be trenched and heavily manured. Raw manure, however, is not good for the roots, and where this has to be used a good plan is to crop the ground once after trenching and before planting the bushes. This answers a two-fold purpose, as it enables the manure to become mellow and gives the ground a chance to settle. All manuring done after planting should be in the form of an annual mulching, and no digging should ever be permitted between the bushes.

Planting Apples.—The right time to advocate the claims of any class of fruit is during the planting season, so that intending planters may be able to form some idea as to which are the most reliable varieties as regards quality, cropping, and the length of time the fruit will keep fit for use. It must be borne in mind that soil has not a little to do with each item mentioned, but much may, and is done in supplying to the soil whatever element may be found wanting. Not only this, I consider it should be clearly stated by those writing for the benefit of others, what kinds of soil they find certain varieties a success in when advocating their extended culture. The fruits sent with this were grown on a good deep loam, resting on the old red sandstone—an ideal soil for the Apple. Lane's Prince Albert was not so fine last season as is usual with this variety on standards. Last year the trees were literally loaded, and thinning of the fruit was put off from time to time, until it was too late, hence the indifferent fruit. One can tackle bush or pyramid trees, but to thin out fruit on a large-headed standard tree means labour, and just then it is a busy season. The accompanying fruits were grown on bush, espalier, and standard trees respectively.—DEVONIAN.

[With the above note we received some very fine, highly-coloured specimens of Peasgood's Nonsuch, Newtown Wonder, Lane's Prince Albert, and Gascoigne's Scarlet. Peasgood's Nonsuch and Gascoigne's Scarlet were especially fine, showing that even in an unfavourable season the soil has much to do with the high colour invariably found in Apples grown in the West of England, more especially South Devon.—En.]

Pruning Apricots.—Assuming the trees were well attended to as regards pinching in the early summer months, little pruning with the knife will be required beyond shortening back to the second or third basal buds, shoots so operated on to form spurs, and shortening to about one-third their length ill-ripened or very robust shoots, though the latter should have been done in the summer, and the tree root-pruned in October or November if considered necessary. Cut out any dead branches or spurs before training in the past season's wood, in case the tree requires readjusting. It is necessary to lay in annually a certain amount of young wood without crowding, as the finest Apricots are got from these shoots, though good fruit are had from spurs which should be kept as near the wall as possible, as the trees flowering so early in the year are liable to get much more damaged by frost when standing out too prominently from the face of the wall. Be careful the shoots do not come into contact with the nail, which soon causes gumming. Newly-planted trees must be cut back before the buds advance, shortening maiden trees to within 9 inches of the union of scion and stock. It is much better to transplant young trees annually when making strong growth than to cut too much with the knife. The border, which should be quite 4 feet in width, requires the same treatment as advocated for Peaches, after the necessary pruning, cleaning up, etc., have been done.—EAST DEVON.

Request to readers of "Gardening."—Readers, both amateur and in the trade, will kindly remember that we are always very glad to see interesting specimens of plants or flowers to illustrate, if they will kindly send them to our office in as good a state as possible.

GARDEN PESTS AND FRIENDS.

GALLS ON OAK LEAVES.

AMONG fell-down Oaks (common) one tree, about 12 feet high, is covered like the enclosed. I should be glad to know the cause, and whether it is an insect or fungus, and the name? It does not seem to injure the tree at all, as the summer growths appear to be healthy.—SOMERSET.

[The strange growths which you found on a small Oak-tree are galls formed by the grubs of gall-flies. You have sent specimens of two different kinds; the sealy and somewhat conical ones are very common on small Oaks, and particularly on those growing in positions in which their growth is to some extent stunted. They are commonly known as Artichoke or Hop-galls, on account of their resemblances when fresh (in miniature) to a Globe Artichoke or a Hop. The scientific name of the fly whose grubs form them is *Andricus pilosus*. Both males and females are produced from these galls. The latter lay their eggs singly in the buds of the Oak in June or July. The action of the grubs, which are hatched from these eggs, in feeding on the buds, causes them to assume the shape of the galls instead of forming a leaf or shoot; if one of these galls be cut open about the beginning of August, it will be found that slightly embedded in the woody base of the gall is a small, somewhat oval gall, about one-eighth of an inch in length. This is the true gall, and contains the grub; a little later in the season this falls to the ground, and the grub in due course undergoes its transformations. In April the fly makes its way out of the gall. The flies from these galls are all females, and, instead of laying their eggs as their mothers did in the buds, they lay them in the male flowers of the Oak, where their grubs form little oval, hairy galls, very unlike those from which their mothers came. From these galls in June or July, according to the season, emerge flies of both sexes, and the females lay their eggs in the buds as their grandmothers did.

The round gall which was cut open is quite a different gall. It is also formed by the grubs of a gall-fly. They are generally known as Oak-Apple-galls, and are among our largest galls, measuring sometimes as much as 1½ inches in diameter. These galls are formed by the grubs of a fly known as *Biorhiza aptera*, which lays its eggs in considerable numbers in an Oak-bud, frequently selecting the terminal-bud on a shoot. The grubs undergo their transformations in the galls which remain on the tree. The flies which emerge from these galls are both males and females, the latter not winged, or having only very rudimentary ones. They crawl down the stems and make their way into the ground, where they lay their eggs in the roots. The galls which result vary considerably in size from that of a Pea to 3-inch in diameter. The flies which are produced from these galls are all females, and usually make their appearance in December or January. They make their way to the surface and climb up the trees until a suitable bud is reached, when they deposit their eggs in it, and it eventually becomes an Oak-Apple. With many other gall-flies, as with those I have alluded to, two generations are necessary before the metamorphoses of the species are complete. This "alternation of generations" is very unusual, but there are other instances in the animal world. In both the Artichoke and Oak-Apple-galls it will be often found that other insects make use of them as breeding places, so that several different kinds may be bred from one gall.—(G. S. S.)

NOTES AND REPLIES.

Leaf curl.—I will be very glad if you can inform me if the leaf curl mentioned in GARDENING, Jan. 31, is what attacks Rose-trees—it has puzzled a good many round here—and, if so, where the Bordeaux mixture can be obtained, if suitable for them?—CHESHAM.

[No; the leaf curl of Roses is caused by a maggot, which can be found enveloped in the leaf. Only handpicking will avail to clear off this pest. We have given the recipe for making Bordeaux mixture frequently in our pages.]

Insects in Rose-bud (H. H.).—The insects which you sent are the grubs of a small fly belonging to the family Anthomyiidae, many members of which are injurious to the roots of plants, particularly to various kinds of Cabbage. They do not, as a rule, attack plants which have only fibrous roots. You do not suggest that they have injured your Roses; many of these grubs feed on, decaying veg-

table matter. Perhaps your Roses have been heavily manured or mulched, in which case the grubs have probably fed on the manure. You would be quite safe in sowing Peas later on, as the grubs would by the time the Peas germinated have become chrysalides, in which condition the insect is perfectly harmless.—G. S. S.]

Grubs in soil.—As I am much troubled with the enclosed grubs, could you give me any idea of its cause, and what are the best remedies? I have them in pots as well as outside. I have lost a lot of *Cinerarias* through them. The plants seem to droop as if dry, then suddenly die. The enclosed were among *Rhubarb*, and are simply swarming there. What could I do not to harm the *Rhubarb*?—J. HITCHINS.

[The insects at the roots of your *Rhubarb* are grubs of a fly, but I am sorry to say I cannot give you its name. It is very difficult to destroy grubs when at the roots of plants without injuring the latter. Many insecticides, such as paraffin emulsion, tobacco-water, etc., would no doubt kill them if it could be made to reach them properly, but passing through an inch of soil takes much of the strength out of the liquid, and even then it is a question if any reaches the grubs so as to cover them. Unless you find that they are actually feeding on the roots of the *Rhubarb* it is possible that they are living on the vegetable matter surrounding the *Rhubarb*. If *Cinerarias* or other plants in pots are attacked, as soon as they show the slightest signs of flagging they should be shaken out and the grubs removed. I cannot suggest any better remedy, though it is a tiresome one.—G. S. S.]

The Apple-blossom weevil.—Last year I had a fair show of Apple-blossom, but no Apples. The buds of bloom died off on the trees. I noticed there were maggots in them. I also noticed a good many flies about the trees, large flies like blue-bottles, only greyer in colour. If you can advise me what to do, so that I may stand a chance of getting a few Apples this year, you will most oblige.—BORTH.

[From what you say, we expect your Apple-blossoms have been attacked by the grubs of the Apple-blossom weevil. These weevils gnaw a small hole in the centre of the flower-bud, in which is deposited an egg, which is hatched in a few days, the grub at once beginning to feed on the interior of the bud, and becoming a chrysalis under the shielded, unopened petals. It would be advisable before the buds show any signs of opening to spray the stem and branches with a caustic wash, for the weevils often pass the winter in the cracks of the loose bark. They also hide under any rubbish at the foot of the trees or in the Grass, so that by keeping the trees clear round the roots much may be done to prevent an attack. A good recipe for the caustic wash is as follows: Put 1 lb. of caustic soda into a gallon of water, then add 3 lb. carbonate of potash, stir until all has dissolved, then add nine gallons of water. Last of all, add 10 oz. of soft-soap that has been dissolved in hot water, stir again, and when all is well mixed it is ready for use. Be careful that none of the wash touches the hands.]

Worms in soil.—I am sorry the little insects which I enclosed to you a week or two ago got dried up in transit. I enclosed some more of the same kind, which I trust will reach you in a good state of preservation. I shall feel grateful if you will kindly tell me what they are, and their cause and cure? They are most destructive to plant life, especially soft-wooded plants. I never see anything like them till about twelve months ago in my garden or plant-houses.—A. WATSON.

[Your second consignment of pests reached me in good order. They are most wonderfully related to the earthworms, but belonging to another family—the Enchytraeidae. Several members of this family are very injurious to the roots of plants. If placed in lime-water they die in the course of three minutes, so I imagine they might be killed by soaking the roots of the plants with this liquid, which should not injure the latter. In the case of plants in pots, when repotting them care should be taken to prevent any of the soil which might contain the worms or their eggs from coming into contact with the soil that is not infested on the potting bench. It would be better to turn the soil on to a sheet of paper than on to the bench, where some of the pests might get into cracks, etc., and afterwards get amongst noncontaminated soil. I cannot find any accounts of experiments having been made to destroy these creatures, and I have had no opportunity of trying any myself, except that of the lime-water, which seems very successful if the worms can be brought thoroughly into contact with it.—G. S. S.]

TREES AND SHRUBS.

FLOWERING SHRUBS.

FLOWERING SHRUBS, of which there is an ever-increasing supply comprising many lovely new species and varieties, are, when rightly used, capable of rendering our gardens interesting and charming from midwinter until autumn. Especially is this the case in the warmer localities of our islands where many tender subjects remarkable for the beauty of their foliage or flowers flourish unprotected in the open air. Such a spot is represented in the accompanying illustration, which shows in the foreground on the left hand an example of the sword-leaved *Cordylina australis*, backed by a vista of blossoming *Rhododendrons*. At Christmas-tide and through January the *Winter Sweet* (*Chimonanthus fragrans*) bears its deliciously fragrant yellowish flowers, inconspicuous when the shrub is trained to a wall, as is the usual custom, but a pretty sight when grown in bush form with a background of some dark evergreen, such as *Yew*. Another striking winter-blooming shrub is *Homamelis arborea*, whose bare branchlets are thickly studded with flowers resembling narrow twisted

shrub perceptibly diminishes, and of those that bloom in August, the list is decidedly limited; but the fewer their number the greater their value, and such as *Arolia spinosa*, *Pavio macrostachya*, *Hibiscus syriacus*, *Clerodendron trichotomum*, and *Indigofera Gerardiana*, in a warm site, are doubly welcome.

Any note on flowering shrubs would be incomplete without a reference to *Rhododendrons*, a host to themselves. Though hundreds of thousands of *Rhododendrons* are grown in the British Isles, only many of the rarer species and varieties flourish in widely separated districts, it is in southern Cornwall that these glorious flowering shrubs can be studied to the best advantage. Their flowering season extends from October, when *R. Nohleanum venustum* commences to bloom, until early June, at which time the grand *R. Nuttallii*, with white blossoms 5 inches in diameter, and *R. Dalhousie*, with large yellowish-white flowers, may be seen in the open. Among the most notable examples in Cornwall are the great *R. Falconeri*, at *Tregothnon*, 22 feet in height and 30 feet in diameter, which in 1902 bore over 1,000 bloom-trusses; *R. argenteum* or *grando*, 16 feet in height, in the same gardens, which last year carried over 300 bloom-trusses; the splendid

bark to stop its cells. This reminds us of a *Magnum Bonum Plum* we saw growing against a wall in the same garden alluded to in *re* *Conifers*. It was a very old tree, whose centre was entirely decayed—in fact, a large hole right through the stem—and the only thing that sustained the tree, which bore heavy crops, was a very small piece of bark on the one side of the tree, which had been treated as above with good results.]

Hedges of Yew and Beech.—The combination of the above well-known plants makes a splendid hedge, and one that may be quickly raised. All who have planted *Beech* are aware how it is apt to become thin at the base, but by mingling with the plantation a number of common *Yew*, the latter supplies an excellent base. How our *Rose* gardens could be shielded from cold north and east blasts if such a hedge were planted in the aspects named. In May and June nothing in the foliage way appears more lovely than the tender *Beech* foliage, and in autumn and winter the russet-brown is also picturesque. —*Rosa*.

The Sea Buckthorn (*Hippophae rhamnoides*).—Shrubs in flower being at this time of

the year very few, those with ornamental fruits now assert themselves, there being a great choice of these open to the planter. In the colour of its berries, however, the *Sea Buckthorn* stands out almost alone, as they are of a bright orange tint, without any of the shades of red which are so prevalent. The *Sea Buckthorn* is in itself a handsome loose-growing shrub, thickly clothed with silvery *Willow*-like leaves, while the shoots of the previous year are closely packed for some distance with these bright coloured berries, which are about the size of *Peas*. It is essentially a moisture-loving plant, and is never so happy when planted close to the water, so that the roots can obtain as much moisture as they need. In planting this delightful shrub it should be borne in mind that the male and female flowers are produced on different plants, hence to ensure berries the two sexes must be planted close to each other. If planted in a group one male plant will be sufficient to ensure the fertilisation of half-a-dozen females. —*X*.

A supposed Desfontainea.—I shall be pleased to receive the specimen referred to by "M. A. H.," page 618, at any time, there being no danger of its slipping my memory, as, strange to say, the greater portion of my schoolboy days (now, alas! a long while ago) was spent at *East Budleigh*, in which village the cheryard occupies such a prominent position. More than this, my youthful love of flowering trees and shrubs was first awakened, and then further stimulated, by a particularly fine specimen of the *Orange Ball Tree* (*Buddleia globosa*), which, forty years ago, flourished in the neighbouring hamlet of *Kersbrook*. —*W. T.*

Shirley Popplee.—No flower borders, where sunshine reaches, need be wanting for gayness in the summer so long as *Shirley Poppy* seed is obtainable. Presently will be the time to make a sowing which should be very thin, as if this is not done the seedlings smother each other. The fine seeds will not need more than just covering with soil. Thinning the plants is almost a necessity, as it is those having the most room which afford the finest blossoms. A pinch of soil should be

A garden vale of hardy flowering shrubs. From a photograph sent by Miss Sophie M. Wallace, Ardnamore, Lough Eske.

trips of gold-leaf. Towards the end of February and in the earliest days of March *Vuttalia cerasiformis* commences to perfect its drooping racemes of small white blossoms, closely followed by the *Cornelian Cherry* (*Cornus mas*), whose little flowers, their petals standing out like wheel-spokes, cloud the shoots with pale yellow. *Prunus Davidiana*, both in its white and rose-coloured forms, is generally in flower in January, as is that noble leafy *Erica codonodes*, which often exceeds a height of 6 feet, and the sweetly-scented bush *Fonysuckle*, *Lonicera fragrantissima*. In the south-west the great *Camellia* bushes are in flower more or less from November to May, and when at the zenith of their display, their shoots drooping beneath a wealth of blossom, white, pink, or crimson, present a charming picture. *Camellias* are hardier than *Laurels*, and in the colder districts their flowers, borne in the winter and early spring, are almost certain to be roodeder unsightly by frost. The *Almond* blossom, expanded in yet spring has dispossessed winter, followed by numerous other early-flowering shrubs, whose ranks are ever augmented as the days lengthen, until the gardens are embowered in their prodigal blossoming. As the summer matures, flowers of *Crab* and

R. Aucklandi or *Griffithianum*, at *Killow*, 13 feet in height and 22 feet in diameter, now nearly 40 years old, that last year was smothered in its great white blossoms: the unequalled specimens of *R. arboreum* and its hybrids, some of them over 25 feet in height and 30 feet in diameter, at *Tremough*, where fine examples of *R. Falconeri*, *R. Aucklandi*, and other rare species are also to be seen. Of other handsome species and varieties to be met with as large bushes in the open are the crimson *R. barbatum* and *R. Shiloni*, *R. fulgens* (almost scarlet), the pale yellow, honey-scented *R. campylocarpum*, *Lady Alice Fitzwilliam*, *Countess of Haddington*, *Beauty of Tremough*, and others too numerous to name. *S. W. F.*

NOTES AND REPLIES.

Decay on tree trunk.—In reading this week's *GARDENING*, I find, in answer to query "Decay on tree trunk" in notes and replies, that you state that *Stockholm tar* ought not to touch bark of trees. Does this apply to fruit-trees, and, if so, please give reasons?—*S. W.*

[Yes, the remarks given upon this subject in our issue for the 31st January apply to fruit trees as well as *Conifers*, and our reason in so advising is that we have always found the bark of damaged trees heal over very much quicker than the bark which has been placed over the

sown on a partly shaded border, as it is from plants grown there that one may obtain blooms that do not drop their petals prematurely.—WOODBRISTICK.

PLANTS AND FLOWERS.

ROOM AND WINDOW.

PLANTS IN ROOMS AND WINDOWS.

Would you kindly let me know some of the best plants for indoors, and how to manage them without a greenhouse? I should be so much obliged if you could give me some hints.—PEPPERED.

[To grow plants in dwelling rooms and windows, in houses where gas is used and fires are regularly kept throughout the winter, further than this, to maintain them in good health, though often attended with difficulties, is not altogether impossible, as some people appear to think, provided certain common-sense rules are followed. In the first place, plants intended for rooms should be obtained when young, as it invariably happens that failures occur to those that are fully grown—generally speaking with specimens forced into bloom with one special object—viz., for sale—and the changed conditions of temperature of the warm, humid atmosphere of a greenhouse, to the dry and not infrequently impure air of a room, quickly bring about an alteration for the worse. One may mention Fuchsias, (clouses, Polargoniums, Heliotropes, Heaths, Azaleas, etc., as examples of this—plants that present a beautiful appearance when offered for sale, but soon deteriorate by so radical a change, and in many instances where one has no greenhouse in which to place them, so that they may have a chance of recuperating, they die off. In order to minimise loss the wisest course to adopt is to procure plants when quite young, so that they may become acclimatised early to the conditions of the rooms.

What are the best fine-foliaged plants, and when is the proper time to obtain them, are questions frequently asked. None give greater satisfaction than smooth-leaved subjects like Aralias, Ficus elastica, and Aspidistras. To this list of fine-foliaged plants one may add Asparagus, like plumosus or nanus, and Cyperus alternifolius, whilst hardy Ferns and Silver and Golden Ivies, trained on frames, are often found useful in rooms where much sunlight cannot enter. If these are obtained young, potted on as they require it, the chances are that success will follow, other cultural directions, of course, being adhered to, whereas fully developed plants from greenhouses often turn yellow after a few weeks in their new surroundings.

With regard to flowering plants for a room, there are many suitable hardy flowers. Campanulas, Spiræas, Pyrethrums, Chrysanthemum maximum, Irises, Lathyrus latifolius albus (for halls and odd corners) are a few of the many plants that may be potted up. Then, again, what cannot one do towards beautifying a room with bulbs? In the autumn, Hyacinths, Tulips, Spiræas, Creceuses, Snowdrops, Scillas, and Narcissi, if potted and brought into the window when growth is showing, will make a place charming weeks before outdoor blossoms open, the chief difficulty being the keeping of the pots and plants in a dwelling house before they can be brought into a window. There are not many houses where space cannot be found for them, perhaps a spare room, and anyone specially interested in plants and flowers will find a way to achieve the object in view.

To keep plants healthy, keep the atmosphere as pure as possible by admitting fresh air every day, remove them occasionally to other rooms where gas is not burnt, water only when they need it, shade them from hot sunshine by drawing blinds, attend to them daily—in other words, treat them in a reasonable manner. Fuchsias, Balsams, and Mimuluses make good window-plants, the two latter being raised from seed in March, but often suffer through inattention in shading them from hot sun. The one also who desires a show of autumn flowers in the window is scarcely likely to overlook procuring a few of the early-flowering sorts of Chrysanthemums in May, and potting them on or plunging them in the

borders until September, when they will lift with little or no harm. You may not have a scrap of "glass," but, nevertheless, you may keep your window gay for many months in the year by a little scheming and planning.]

Freesias as window-plants.—It is quite possible to grow this fragrant flower successfully in rooms. Specimens with seven or eight good spikes may easily be had in May or June, if a few necessary details are attended to. In the first place it is incumbent that good, strong bulbs are obtained. The bulbs that are offered at a very cheap rate are seldom of much good—they either throw up weak flower-spikes, or do not bloom at all. Get them from a reliable source, pay a fair price for them, and you will get some satisfaction from their culture. Five bulbs may be put into a 4½-inch pot, or eight into a 6-inch pot, the compost to consist of loam with a liberal addition of leaf-soil. They should be potted about the middle of August, and the best way is to stand them in the open-air in the full sunshine, watering only when dry, and very moderately until the end of September. In this way the bulbs will start freely, and make short, sturdy growths of a couple of inches before it is time to put them indoors. On no account must they be wintered in a close, constantly-heated apartment—they must be kept where air can be admitted in fine weather, for Freesias continue to make steady growth all the winter in a temperature of from 45 degs. to 50 degs. Water only when dry and moderately, until the bright days come, and then more freely. A little weak manure-water should be given when the flower-spikes appear. After blooming, water until the foliage dies away, and then stand the pots where they are fully exposed to the sun. This is absolutely necessary.—BYFLEET.

INDOOR PLANTS.

THYRSACANTHUS RUTILANS.

I HAVE some plants of *Thyracanthus rutilans* with plenty of foliage. What heat do they require, and what treatment to induce them to flower?—READER.

[At the present day many of our fine flowering old plants are in danger of being lost, the plant about which you inquire being one of them. Some thirty years ago this used to be found in every garden where there was a stove. It blooms during the first three or four months of the year. The flowers, which are tubular in shape and rich bright crimson in colour, are borne in long drooping panicles, so that a plant of it when about a yard high is more effective than when dwarf. It usually runs up with a straight stem that loses the leaves towards the lower part, and consequently the flowers are the more noticeable. It lasts some time in bloom, the spikes coming in succession when the plant is strong. For cutting the flowers last well, and are very useful for suspending over the sides of tall pergolas. After flowering give the plants a slight rest, keeping them dry at the roots. What little pruning is necessary should then be done.

Planting is best done when growth is starting, using turfy loam chiefly with some good peat. It is well to strike a few cuttings every year to keep up the stock. These should be trained on a single stem until about 2 feet high, when a head may be formed. As soon as the warmer weather comes round—say, any time in May—the plants can be kept in a house where the temperature is less than in a stove. In favourable localities the plants are quite safe out-of-doors from June to September, keeping them in a sunny place. Brown scale is the worst enemy the *Thyracanthus* has. Care should be taken to keep this down, otherwise the plant will be spoiled.]

NOTES AND REPLIES.

Acacias from seed.—In buying some *Mimosa* the other day I was fortunate enough to get a piece with a seed-pod on. Will you kindly tell me if I can raise these acacias in a greenhouse, and the best treatment for them?—E. C. B.

[We fear your seed is of little value, as it is not ripe. You can, however, try sowing the seeds in sandy peat in February or March, and standing on a hotbed. Soak the seeds in warm water several hours before sowing.]

Geraniums dying off.—Will you kindly inform me the reason for the rotting away of *Geraniums* (I have in a greenhouse heated by a small gas apparatus?) They

start by turning black at the top of the plant, and gradually work down to the roots. If the top be cut away a mildew seems to adhere, and rotting again takes place. I have sent cuttings to more correctly describe what I mean.—F. M.

[Are you quite sure that none of the fungus can reach the plants, as, if so, this would probably be the cause of failure? Or it may be that you are keeping them too wet at the roots, the atmosphere also being damp and close.]

Carnation Deutche Bruant.—In a recent issue of *GARDENING*, "A. W." praises the above tree or winter-flowering kind. The thing that surprises me in the note referred to is that the variety in question is, according to "A. W.," "quite first rate." I would not even class it so high as second rate; indeed, I would not give it room to-day, for I know of no white Carnation that produces so many blind buds, and so much material that is useless. The experience of "A. W." is limited, however, and it would also appear he has disabused his plants by the reference to "about five blooms expanded on a plant." Those are probably the first or crown-buds. If not disabused these will not only be the first, but the last of any value. It is a type of Carnation I could never regard as "first class," for the petals in form is quite third class, and not less so in its smallness. "A. W." compares this kind to *Mlle. Carlé*. There are many who fail to grow this latter with success. Those who do, however, know that in *Mlle. Carlé* almost every flower will expand, while in *Deutche Bruant* the lateral blossoms, when these open at all, are one-sided and inferior. If "A. W." really wants a winter-flowering Carnation to "quite first rate," he has only to get *Ma S. J. Brooks*.—E. J.

Gloriosas.—It is doubtful whether we have amongst warm greenhouse plants climbers that are more gorgous when in blossom than the subject of this note, the *Gloriosa*, and now depending from the roof of a conservatory the flowers are most attractive. One cannot say that the *Gloriosa* is easy to grow in the sense we may speak of *Clematises* or *Paeonifloras*, as, being of a tuberous growth, the plants require more careful treatment, but all that they do not need so much as many people imagine; indeed, in houses where a minimum heat of 55 degs. to 60 degs. is kept up, there the *Gloriosa* will flourish. When the flowering season is over and the dead stems and foliage have been cut away, the pots should be laid on their sides until spring, out of reach of damp and frost. In March the tubers should be carefully taken out of the pots, the old soil removed, and repotted in a compost of peat, loam, leaf-mould, and sand, with cow-manure in equal parts, particular care being taken to see that drainage is perfect. Place the pots in the brisk heat of a propagator, and avoid giving much moisture until growth has commenced, after which water may be given liberally. A moist, humid atmosphere suits *Gloriosas*. Training of the shoots up the rafters should commence early, as if deferred there is a liability of them breaking off. *Gloriosa superba* is one of the best known flowers being orange-red and yellow.—W. F. C.

Lachenalias in pots.—How sad! *Lachenalias* are, yet of late years they seem to have fallen into disrepute, if one may judge by the comparative few that are now met with. They require to be potted in good rich material and grown on all winter in a cool greenhouse temperature well up to the roof glass. The least coddling causes the foliage to become drawn and flabby, and the flower spikes correspondingly poor. Two parts good holding manure and one part thoroughly decayed manure suit them well. Weak liquid manure may also be given three times a week with advantage when the bloom-spikes are developing in the spring. For arranging in baskets with *Cyclamens*, *Primulas*, and small Ferns they are most useful. Some gardeners grow them in ornamental wire baskets in a compost of loam, Moss, and manure. The young plants are pricked into the top, bottom, and sides of the basket, which is then suspended from the roof of greenhouse or conservatory, and regularly watered throughout the winter. In March and April their graceful mottled foliage and golden flower-spikes form a pleasing contrast and are very elegant. After flowering, the plants should be placed out-of-doors at the base of a wall where only a small amount of sunshine

reaches them, and be allowed to take care of themselves until September, and when half an inch of new growth has been made they should be shaken out, the flowering bulbs separated from the small new offshoots, and repotted. When the plants are left in the same pots two years in succession both foliage and flowers will be meagre.

CHRYSANTHEMUMS.

CHRYSANTHEMUM PHOEBUS.

Though not a new variety, this is still much grown, partly on account of its clear yellow colour and sturdiness of growth when the plant is allowed to carry but three blooms from the first crown-bud. It was thought when Modesto appeared Phœbus would be ousted,

"big or fat" exhibition flowers which sustain the interest in Chrysanthemums and are the mainstay of the shows. What I do object to is the statement "that the trade make it their business to knock out varieties that have been favourites after a couple of years because old varieties have become plentiful and cheap." As a trade grower and raiser I must take exception to it. "A. Dean" adds further, "that it is done by forcing on growers new varieties that can hardly be said now to show advance or diversity on the old ones," and also, "Chrysanthomum showing has been a fine trade boom, but it has seen its best days, happily." Quite true all the introductions do not turn out trumps, but is it not the same among Roses, Peas, Melons, and other flowers, vegetables, and fruits? The trade must retain a variety long after it is superseded

last two years, and the last-mentioned dozen are practically novelties of the past season. Is there another plant which sustains the same interest, and it was never keener than at the present time! The public (or growers) are not foolish enough to pay year after year several shillings for a variety when an old one equally good can be purchased for the same number of pence.

W. J. GODFREY.

[Is it not a fact that an exhibitor, if he wishes to be in the front rank, has a far better chance if he includes in his twenty-four or forty-eight blooms all the novelties of the past year—we mean those kinds that have been recognised either by the N.C.S., or the R.H.S.? Size now seems to be the rule, and unless a flower has this to recommend it, any other good points it may have are ignored. Raisers concentrate their efforts on size, and we have frequently seen an otherwise good bloom in every way passed over because this attribute, so necessary in the eyes of many, is wanting.—Ed.]

Amateurs' Chrysanthemums.

— It seems somewhat presumptuous on the part of "S." to say how many or how few Chrysanthemums an amateur should grow. Surely that matter is decided by taste, time, and space of each individual. I easily grow fifty to sixty plants, and have done for twenty or more years, formerly exhibiting; but, as I said in the query you were good enough to insert, I am now right away from any place where they are grown in quantity, consequently, have no means of seeing new varieties in growth, and making my own selection. Neither have I sufficient knowledge to know the capacity of a plant by seeing a mere name in catalogues, which, by the way, seem compiled for exhibitors only. Every grower knows there are kinds which only the very highest culture will bring to a satisfactory bloom. On the other hand, there are many varieties up to exhibition standard which will give a very satisfactory result without making too much demand on one's time and strength. Hence my query. As to the number, that is a mere detail, so I will amend it by saying any new (I emphasize new) varieties which answer this description. — NORTH CORNWALL.

Phœbus, a useful Chrysanthemum for market.

but though the colour is a deep golden-yellow, the plant is not nearly so strong in growth. The flower of Phœbus is of good depth when well grown. In growth it resembles Avalanche, and it is a great pity that more of the newer varieties do not take after this, as some of them are far too tall. J. M. B.

CHRYSANTHEMUM BLOOMS IN VASES.

"A. DEAN" has expressed his opinion on page 629, and whilst agreeing with much of what is stated, I must take exception to his remarks in respect to the raisers. I quite agree with him that the exhibition of blooms in vases should be encouraged, but join issue with him respecting the remark that the public are rebelling against the "big or fat exhibition flowers" in vases. I quite appreciate the medium-sized flowers known as "market stuff," but it is beyond dispute that it is the

because some growers will demand it, and it is only when a variety is not asked for that the trade grower can discard it. I have to retain scores of out-of-date kinds because they are ordered, and it would be useless to "knock out" any popular and good variety because it was old. Do not new varieties show any advance on the older ones? I will mention twenty-four Japanese sent out during the past three seasons, and ask "A. Dean" to name the same number sent out previously that are equal to these: W. R. Church, Mrs. G. Mileham, Mrs. Greenfield, Mafeking Hero, Kimberley, Henry Stowe, Chas. Longley, Mrs. Herrewige, Loveliness, Lily Mountford, Miss Alice Byron, Calvat's Sun, Mrs. Bagnald Wilde, Mme. Paolo Radaelli, General Hutton, Bessie Godfrey, Ethel Fitzroy, Duchess of Sutherland, Sensation, Godfrey's Pride, Mrs. E. Hummell, Mrs. J. H. W. Ermouth Crimson, and Ben Webb. Most of these are introductions of the

number, that is a mere detail, so I will amend it by saying any new (I emphasize new) varieties which answer this description. — NORTH CORNWALL.

Lobelia cardinalis.—I note the article on herbaceous Lobelias by "S. W. F." in your issue of January 10th, just to hand. *L. cardinalis* is indigenous here on the borders of swamps, where coarse Grasses crowd around it. Sometimes during our winter months the thermometer falls to 23 degs. below zero, yet this species and its allied form *L. sylvatica* do not succumb. *L. cardinalis* is a shallow-rooted plant, and when brought into my garden and planted either in a rather stiff clay loam or in the finer black soil in which it is found native, it is heaved up with the frozen soil and dies. Laying an inverted sod over the plants in the fall often brings them through the winter safely, but I find that the best way is to winter

the old plants in a cold-frame, tear to pieces and put in the early spring, and plant out later on. My impression is that it is not the severe cold affecting the plant itself that winter kills it, but the upheaving of the shallow roots, which in their habitat are held down by the numerous interlacing roots of the neighbouring Grasses.—H. C. EMAN, *Egansville, Highland Park, Illinois, U.S.A.*

ORCHIDS.

ODONTOGLOSSUM CRISPUM.

ODONTOGLOSSUM CRISPUM was first discovered in 1842, near Pacho, in the province of Bogota, by Carl Theodor Hartweg, when collecting for the Royal Horticultural Society of London, and was described from Hartweg's specimens by Dr. Lindley under the above name. Blunt secured plants in 1863 while collecting for Messrs. Hugh Low and Co. The first plant

months. I do not want to convey that during periods of severe frost the falling of the temperature to 40 degs. inside the house will do the plants harm, provided the atmosphere is dry and the plants also dry at the roots. In the hands of an experienced man no harm will happen with the low reading of the temperature for a short time. The nearer we keep the plants to 55 degs. by the use of artificial heat, if under or by ventilation when the temperature rises, the better. In summer the difficulty arises of keeping the plants sufficiently cool. A house with a north aspect is generally found the most suitable for these plants during the summer. A span-roofed house will meet all requirements from September to April. A cool, pure atmosphere, the latter heavily charged with moisture whenever the normal conditions of 55 degs. are reached, is one of the principal requirements of *Odontoglossum crispum*. Froo ventilation as soon as the normal conditions are reached and the

OUTDOOR PLANTS.

NOTES AND REPLIES.

The Shasta Daisy.—Can you or any of your readers give me any particulars from personal experience of the Shasta Daisy (*Chrysanthemum leucanthemum* hybridum)? (The catalogue describes the flower as a foot in circumference, and another nearly a foot in diameter—a rather wide difference. Are the outside white florets long, or is all the flower taken up with a large centre of tubular florets?—A. G. SAVILE.

Value of carbon.—Can you tell me whether broken pieces of carbon are of any use as a fertiliser either in the fruit or flower garden?—KILINN.

[The stuff you mention would not be of the slightest value in any way to the soil. Plants obtain their carbon from the carbonic acid gas contained in the atmosphere, and in the air of the soil, and these media furnish an unlimited supply.—C. F. FERRIS-PHOSOR.]

Water rats.—I am greatly troubled by these pests, which infest the lake in my garden, and shall be thankful for reliable information how to get rid of them. They have made huge runs in my beds of Japanese Iris, the bulbs of which they devour, and disaster follows their visits to my Marillac Water Lilies; in fact, anything choice

Odontoglossum crispum. From a photograph by G. A. Champion.

to flower was in Mr. John Day's collection at Tottenham. Mr. Bateman failing to recognise the plants sent home by Weir, who collected for the Royal Horticultural Society, mistook them for a new species, and named them *O. Alexandra*, in compliment to our present Queen (at that time Princess of Wales). Reichenbach fell into a similar error in respect to Messrs. Low's plants, and gave them the name of *Odontoglossum Bluntii*.

O. CRISPUM is an alpine species, found in its native habitat at an altitude of 7,500 feet to 8,500 feet elevation, and therefore requires cool-house treatment. I want readers to understand my definition of "cool-house." I saw in one of the gardening papers recently an article written by some one who recommends certain species of Orchids for cool-house culture and gives a temperature of 45 degs. sufficient for winter requirements. With a general statement of this kind I cannot agree. The normal temperature for my cool-house Orchid should be 45 degs. during the winter

outside state of the weather permits is also important.

POTTING of established plants is best done in the autumn about September, but as the plants do not all make growth at the same period, they must be dealt with when they are omitting, or about to emit, new roots from the base of the developing growth. The compost I find suitable is a mixture of Oak or Beech leaf-soil, fibrous brown peat, and chopped Sphagnum Moss, with sufficient rough sand to render the compost porous, surfacing the top with Sphagnum, and pressing moderately firm. In the pots Bracken-roots take the place of the usual potsherds to the depth of about one-third. The plants are procured at a moderate outlay either as unflowered semi-established plants, or in an imported state for a moderate outlay of a few shillings. Why I advise purchasing imported and unflowered plants is because one never knows what such plants may be worth until the flowers have expanded.

seems to particularly attract them, and they are increasing to such an extent that the position, from a gardening point of view, is becoming serious.—M.

[We find common gin-traps will catch them, and in that way you can exterminate them more readily than you can the common rat by the same means. Cats help, and also weasels, if you can afford to have a nest of these any way near. The rats are easily shot with a rat gun.]

Olematisses failing.—Will you please say the nature of the soil required for the successful growing of *Olematissa*? I have tried a great many kinds of this plant, and with the exception of Jackman's they have all failed. When first planted they grew well, but as soon as they attained a height of from 5 feet to 10 feet they died away, and did not come again. My garden was an old orchard, with rather heavy loam, which, in the winter, is inclined to be wet. Thinking that the failure was due to the heavy nature of the soil, I mixed a good quantity of well-decayed leaf-mould and sharp sand with it. I have tried both autumn and spring planting, but without success.—PADDY.

[A light loamy soil is the best for *Olematisses*, and if there is any lime in it all the better. Thorough drainage is indispensable, and want of this is possibly the cause of your failure. Attention must also be paid to feeding, using only a dry, hot soil, and mulching of cow-manure.

whilst on such as yours a dressing of leaf-mould would be useful. It may be, too, that all your plants have been grafted. The stock used is *C. viticella*, and though a vigorous growth is obtained at first, they perish in the end.]

Planting a flower border.—I enclose you a rough tracing from plan of a portion of my garden, which is situated in the country, and where a stiffish soil obtains. Roses, Strawberries, and all kinds of shrubs, etc., thrive well. I am a constant reader of your paper, and also of your books, and I therefore know that my plan of a formal garden will not meet with your approval, but I feel sure you will help me in a little matter where I find some difficulty, and that is in furnishing at not too great an expense the long border "A" with herbaceous plants. As you will note, there is a tall pergola at the back, which, however, has only just been planted with climbing roses, etc., and although eventually they will look all right, at the moment they are gaunt and not pretty. Will the taller herbaceous plants detract from the pergola? Should all the plants be now put in, or is it not too early for some and too late for others (bulbs, etc.)?—F. R. M. *WILTSHIRE*.

[You are misled, like so many others, by the loose talk of the formal garden, and a straight border by a straight wall may and should be planted picturesquely. If a garden with a straight outline be formal, then all the beautiful cottage gardens of England would be so; but it is nonsense. Hardy flowers, we should say, would do very well in the place you describe. There is no royal road to get them. Many are easily raised from seed, many may be got in cottage gardens, many are offered in quantity by some of the trade houses, whose notices you will see in our columns, and many may be got by exchanging with friends.]

Tank leaking.—I have a small pond in my garden, triangular shaped, having sides 15 feet long. It is 3 feet deep, and is formed of concrete and cement, but I am troubled by its continual cracking. I wake up in the morning to find that all the water has run away during the night and left the Water Lilies, etc., dry. As soon as I have one place sealed up its cracks in another, with the same result; and last year, when I was away from home, the aquatics and fish were all destroyed. As it forms, when filled, a very effective ornament to the garden, I intend this spring to have it properly repaired, if this is possible without running the risk of its further breaking. It is on somewhat sloping ground, and has three large trees round it. I am wondering whether I could have it lined with zinc or tin. I shall be very much obliged to you for any advice you can give me, through the medium of your valuable paper, on the subject.—*POXB, Upper Purwood, S.E.*

[As we know by experience that many tunnels exist underground in or near your locality, we have thought the continued breaking may be due to this and the continued oscillation produced. This would need be very great to affect it in the way described, however, and we rather attribute the cause to defective work, and mainly due to lack of strength in the materials employed. If the leakage is due to any subsidence of the ground, which, with a large amount of water continually percolating through the soil, increases rather than otherwise, the idea of lining with zinc would be of no use whatever. Such material must needs be joined, and the seams would quickly open with pressure. Lead is the only safe article in this direction, but it is costly and, of course, exposed to the same objection as the last. In capable hands there should be no great difficulty in making a perfectly water-tight compartment for the plants, and it may be done in the following manner: In making the excavation for the pond, a further depth of 9 inches should be removed to admit of a bed of well-tempered clay being first tightly rammed in position. Even a foot in thickness of this for the bottom and 2 feet high at the sides would be better, but less than 12 inches in a treacherous soil is not advisable. Over this bed of clay may be placed the concrete, composed of cement and ballast of two-and-one strength. A bottom of 9 inches in thickness, tapering to 6 inches at 2 feet high on the sides, should be given. The upper part may be rendered in a less strong manner. Each of these parts should be fairly set before the new material is added above. Finally, the concrete should be covered with an inch coating of cement and washed river sand in equal parts, and this, again, more for finish than safety, be floated neatly in neat cement. We have every confidence that a perfectly water-tight place can be made in this way. If there is any cause for fear through the nearness of the large trees, a trench may be cut at a safe distance from trees and tank, and in this way cover all roots that are found. We agree with you as to the added beauty and interest of these

aquatics to the garden scenery, and trust you may succeed in your endeavours to make it quite satisfactory.]

Violet Princess of Wales.—From Mr. A. B. Mills, Roseville, Lismore, Waterford, come some very fine flowers of this handsome Violet, nearly as large as some of the *Violetta*

GLADIOLUS HYBRIDUS PRINCEPS.

This was first put into general cultivation by Herr Max Leichtlin some three or four years since, at the high figure of 20s. a bulb; but, like high-priced seedling Dahlias, those who buy at the first often find it is cheapest in the end. It certainly is so in this case, for it

New hybrid *Gladiolus* (*G. princeps*), raised by Mr. W. Van Fleet. From a photograph of a spike grown last summer in Messrs. Wallace's nursery at Colchester.

forms of Tufted Pansy. On the other types, such as the *Czar* and others nearly allied, *Princess of Wales* shows a marked improvement, both as regards colour and length of flower-stem. The stems in the case of the flowers sent were quite 6 inches in length. When the size of the individual flowers is considered, it may be regarded as an abundant

reproduces itself by means of bulbils as freely as some of the seedling *G. Lemoinel*. It has a most vigorous constitution, growing 4 feet to 5 feet high, the flower-spikes, fully 2 feet long, bearing some twenty large flowers of an intense bright scarlet, with white markings in the throat. I measured carefully some of my flowers last summer, and they were 11 inches long from petal to petal. I have little doubt

that in a few years this grand new hybrid will find its way into most gardens, and by reason of its rapid increase will become as popular as the old *G. Brenchleyensis*. The raiser of this fine acquisition was an American gentleman, Mr. W. Van Fleet, who read a paper on the hybridisation of Gladioli before the International Plant Breeding Conference, held in New York last September. In the course of his paper he mentioned *G. princeps*, and I cannot do better than quote his remarks:

"My European correspondents report different results from crossing *cruentus* with other species and garden varieties, the seedlings being inferior to the parents in substance or colouring. This is my own experience in the main, but the first batch of hybridised seedlings yielded the magnificent variety since known as *G. hybridus princeps*. It came from a seed of *G. cruentus* and *G. Chibid*. It is not necessary to describe *princeps* farther than to say it almost exactly reproduces *cruentus* in its scarlet-crimson colouring, with white and cream featherings in the lower segments, but the flat, circular flower is expanded to 10 inches in diameter both ways; the plant is doubled in size in all its parts, retaining the dark green, lustreous, and profuse foliage, and is of a vigour of growth and easy increase hitherto unknown in the genus. It appears to succeed wherever tried, and can doubtless be grown anywhere and in any soil. A peculiarity of *G. cruentus* in developing its flower-spikes after the first buds open is fully retained. When the spike first appears it is short and blunt, looking as if only a few blooms would develop, but growth proceeds until often nineteen to twenty-two of these immense flowers are open, the last being about as large and perfect as the first. This progressive growth continues in water, if frequently changed, almost as perfectly as on the plant. From two to four blooms are fully expanded at the same time, thus giving a flowering period of nearly five weeks for a plot of *princeps*, taking into consideration the successive side spikes and extra flowering growth sent up from strong corms. During this period, from the first of August to near the middle of September, a bed of this variety equals in brilliancy an equal expanse of *Scarlet Salvia*."

Colchester.

R. WALLACE.

CORRESPONDENCE.

Questions.—*Queries and answers are inserted in GARDENING free of charge if correspondents follow these rules: All communications should be clearly and concisely written on one side of the paper only, and addressed to the Editors of GARDENING, 17, Furnival-street, Holborn, London, E.C. Letters on business should be sent to the PUBLISHER. The name and address of the sender are required in addition to any designation he may desire to be used in the paper. When more than one query is sent, each should be on a separate piece of paper, and not more than three queries should be sent at a time. Correspondents should bear in mind that, as GARDENING has to be sent to press some time in advance of date, queries cannot always be replied to in the issue immediately following the receipt of their communication. We do not reply to queries by post.*

Naming fruit.—*Readers who desire our help in naming fruit should bear in mind that several specimens in different stages of colour and size of the same kind greatly assist in its determination. We have received from several correspondents single specimens of fruits for naming, these in many cases being strips and slices of the same. In many cases, so differing between varieties of fruits are, that in many cases, it is necessary that three specimens of each kind should be sent. We can undertake to name only four varieties at a time, and these only when the above directions are observed.*

PLANTS AND FLOWERS.

Ambrosia mexicana (J. R.)—Is a half hardy annual with beautifully veined leaves. It has a peculiar but pleasant scent, and grows about 2 feet high. Its stems are covered with small flowers quite to the top. It is said to thrive best in a rich sandy soil, with full exposure to the sun.

A weedy lawn (C. E. R.)—Seeing your lawn is in such a poor condition, the best thing would be to have it dug up deeply, picking out when doing so all the bad weeds, adding at the same time some good manure. Having allowed it to settle, make it firm and level, and procure some good lawn Grass seed and sow it down early in April. No surface treatment will do any good. The Moss shows that the land is very wet, and would be benefited by being drained.

Amaryllis leaf diseased (H. A. Walker)—This *Amaryllis* disease has puzzled many, and given rise to a good deal of controversy, but it is now generally recognised that it is caused by an excess of moisture, particularly just as the bulbs are starting into growth. Collections where it has given a great deal of trouble have been restored to a healthy condition simply by a sparing use of the water-can till the plants were in active growth.

Lilium aratum and L. candidum (R. M. C.)—1. You cannot do better than plant some of the strong-growing kinds. 2. Your query is very indefinite. You do not say whether your bulbs have flowered or not. Neither do you say when you potted them. If you potted them in the autumn leave them alone, and in all probability they will flower in due course. In any case, it is too late to pot now, and the only thing you can do is to find them when they are coming into bloom.

Echinocystis lobata (J. F.)—The *Echinocystis* embraces about fifteen species of stove, greenhouse, or hardy prostrate, or climbing annual or perennial herbs, all American. In *E. lobata* the flowers are greenish-white, small, and produced from July to September. It is a hardy climber, thriving in a moist, rich soil, and is easily reared from seed. Any gritty, loamy soil will answer for the Saxifraga, giving them a good position in the rock garden.

Cyclamens after flowering (A. B. C.)—The plants that have done blooming should be stood in a cold-frame and watered as carefully as if in bloom. They must be covered with a mat if there are signs of frost. Do not crowd the plants, and as the plants show signs of going to rest the water should be lessened, very little being necessary during June and July. After this, if kept a little moister the young leaves will soon start, when the corms may be shaken clear of the old soil and repotted in a mixture of loam, leaf-mould, and sand.

Pelargoniums repotting (A. B. C.)—As no doubt your plants will be leggy, we should suggest cutting them down rather than shifting them on at present. After having been cut down they should be kept rather dry and to a light position till the young shoots make their appearance, when they may be shaken nearly clear of the old soil and repotted. Put them into small pots as the roots can be conveniently got into, shifting on as may be necessary. You may trim the roots a little.

Roman Hyacinths (Dutchman)—As soon as potted they should be given a good watering, and when the surface soil has dried they may be covered with ashes that have been weathered for the open for some time. Quite half the battle is overcome by potting as soon as the bulbs come to hand, which is usually during the month of August. A great point is to have the bulbs well rooted before introducing to heat, as without this the spikes will be poor and insignificant.

Genistas (O'Donnell a Boo)—These may be cut back after flowering, as they will readily push forth new shoots, especially if they are kept close and syringed occasionally. Should they require repotting, reduce the ball of soil, repot, and keep them under glass for a few weeks until they become well rooted. They may be stood in the open air during the summer, being careful as to watering, as if allowed to become in the least dry the plants are likely to lose their foliage.

Tradescantias (J. C. Bloomfield)—The creeping species of *Tradescantia* are very useful for draping hanging-baskets containing other plants. They are also well adapted for growing as an edging to plant-stoves or trailing over rockwork in the stove. The shoots root like weeds at any season if given a moderate heat and shaded from the sun. When rooted they may be potted off singly, and when fairly established put into their permanent quarters. Two good varieties are *T. discolor* and *T. discolor variegata*.

Deutzia gracilis after blooming (Toxteth)—*Deutzias* that have been forced or flowered in the greenhouse should be gradually hardened off, so that when all danger of frost is past they may be stood out-of-doors. At that time any old and exhausted wood should be cut out in order to allow room for the development of young and vigorous shoots, while, if necessary, the plants may be repotted. The great point is to have the wood well ripened by standing them in a sunny position during the summer, taking care that during growth they never suffer from want of water. *Deutzias* will stand for years in the same pots and flower well each season, provided they are occasionally watered with liquid-manure during the growing period.

Plumbago growing (Grateful)—Want of air and consequently a damp, stagnant atmosphere seem to be at the root of your difficulty, and until this is remedied you cannot hope for much success. In your *Plumbago* in a pot? If so, it is a good time to repot it, and alter this be particularly careful not to overwater till the roots take possession of the new soil. As spring advances syringe occasionally and maintain a free circulation of air whenever the weather is favourable. Is the blight to which you refer a form of insect? If so, vaporise with the N.L. All Vaporiser. If mildew, sulphur will help to check it, but renewed vigour will do more.

Spiraea (Hortia Japonica) (W. Clark)—You can purchase the clumps very cheaply in the autumn, when they should be potted and stood in a cold-frame, covering them with ashes. Introduce them into heat as you want them, taking care that when in full growth they never want for water. It is a good plan to stand them in a pan of water when growing freely. When flowering is over stand them in a cold-frame, watering freely until the foliage has ripened. You can then divide them and set them out in good rich soil, keeping them well mulched with rotten manure, and watering freely during the summer. Let them remain thus for two or three seasons, when they may be lifted and again used for forcing.

Renovating lawn (Hastemere)—When referring to any previous reply it is well to mention the date of the publication. When you are advised to pare off and burn foul or weedy turf, of course, it is supposed to indicate that these turves must lie exposed to the weather to dry, and then before being burned have as much of the soil as possible removed from them. If, however, there be the turf, all the same, more Grass than weeds, by far the best plan is to peg away and cut the weeds out, as then you could by top-dressing with fine soil, sowing good seed over it in April, well raking and rolling it in, in time get a really good lawn. The cost of paring off the turf, burning it, spreading the ashes, reworking the soil, and resowing it with Grass seed, will be considerable, and even then there may come up as many weeds as before. Sulphate of ammonia, applied in May, is a capital Grass manure.

Chrysanthemums—growing plants on the decorative system (Amateur)—We have looked through the list of thirty-four varieties submitted to us for an opinion of their merits for decoration, and find that the majority of them are essentially exhibition kinds. Many exhibition Japanese kinds are quite unsuited for developing freely-flowered plants, although, of course, there are among them varieties equally well adapted for decoration as well as for exhibition. The likely sorts in your collection are subjoined, and no time should be lost in commencing their propagation. Best and most paged, therefore, the following varieties: *Australis* Gold, Vivand Morel, Charles Davis, Lady Hanham, Golden Gate (late), N.C.S. Jubilee, Phœbus, Col. W. B. Smith, Florence Davis, Nirveum, Gloire du Rocher, W. H. Lincoln, Lord Brooke (late), Rayonnaute, and Thomas Wilkins. Decorative *Chrysanthemums* should be grown on to the terminal buds, as this ensures a free display of blossoms, and those resulting from a terminal bud selection are rarely known to suffer from damping-off of the petals.

TREES AND SHRUBS.

Staphylea colchica forced (Toxteth)—This plant requires in a thorough ripening of the wood, which is done by keeping the plant under glass after flowering until frost has gone, and then placing in a sunny position outdoors, watering and syringing daily during hot weather. If you have a good stock of plants it would be well to plant out one-half each year in a well prepared bed, forcing the other half. It gives the same treatment as *Azalea mollis* the plants may be kept in pots for several years by top-dressing and repotting every third or fourth year.

FRUIT.

Grafting Plum and Vine (Norvic)—The present time for grafting a Plum-tree is the middle of April. That end you should obtain some stout young shoots from a tree of the variety you propose to graft on to your old Plum-tree, tie them into a bundle, and bury 6 inches of their bottom ends in the ground in a shady place. By doing you keep the grafts resting longer than they otherwise would be left on the tree. You may behead your wild Plum-tree now back to within 2 feet of where you propose to graft it. Whether that will be on two or three branches or on to a single stem you do not say. But to ensure success, rather than attempting to perform a trying operation, you had far better get some local gardener to do it for you, as it is no easy task. With respect to the grafting that should be done at some time. Vines, however, are usually propagated that is, bringing the young stem of a Vine as yet close to a low down green branch from a Vine, slicing a portion of the bark from each, tying the cut parts together, and in time they grow and become united.

VEGETABLES.

Growing Mint (Taber)—In growing Mint it is advisable to have beds in two aspects—one on a south border for early spring use, and the other on a north border to produce green Mint in summer. It does best in rather light well-drained soil, and the addition of road screenings or old mortar-rubbish is better than manure a stiff, adhesive soil. Mint is easily increased by division of the roots when growth is starting in spring, or by cuttings which may be taken with a root attached when the young shoots are 3 inches or 4 inches long. When taking cuttings thrust a knife into the ground, severing the under ground stem. The little shoots will thus come away with plenty of roots, and may be at once planted in a new bed 6 inches apart each way. A top-dressing of leaf-mould the spring just before the young shoots appear is very helpful.

SECRET REPLIES.

P. B. S.—See article on "Garden edgings" in our issue of Jan. 3 of this year, p. 578. —**J. E. Deane**—See article on "Outdoor aviary" in our issue of Dec. 2, p. 628. —**"Pigeon keeping for Amateurs"**, price by post, 1s. 2d. L. Upcott Gill, 171, Strand. We do not reply to queries by post. —**E. M. P.**—The only thing you do do is to persevere, and directly any scale appears it must wash it off. —**E. P.**—All weed killers are poisonous and have to be carefully used. —**City of York**—We have no idea, as we have no knowledge of the street in question in your district. —**J. E.**—See note in our issue of Feb. 22, 1902. —**Bertram Alder**—See article in our issue of Nov. 9, 1901, which may be had of the publisher, price 11d. —**York**—You ought also to get a copy of "The English Flower Garden," in which the subject is fully dealt with. —**Hydrangea**—From the appearance of the leaves you should say that the fumes of sulphur from the stove have been the cause of the mishap. We have had the same thing happen several times. —**Flora**—You cannot do better than follow the advice given to "Flora," "Roses for bank." In our issue of Feb. 7, p. 602. —**Variegata**—You cannot do better than get a variety named *Reine Olga*, the finest *Grape* we have seen for outdoor culture. —**Tyrro**—1 cwt. per acre = roughly 180 lbs. per rod; 5 cwt. (a dressing often given) = about 112 lbs. per rod. If you can mix some old potting soil with it, it will be the better. 2. Cut your *Coronilla* back immediately after flowering, but the less cutting the better. —**Thornhill**—"Hobday's Villa Gardening," from our office, 6d. post free. —**Chill**—Write to some of our best seedsmen, who will be able to advise you. —**Capota**—Just the position for the many beautiful hardy *Ferula* either planted out or in pots. —**R. M. T.**—We suppose you mean the *Belladonna Lily (Amaryllis Belladonna)*. You will find it figured and treatment given in our issue of Nov. 2, 1901, p. 469. —**J. C. P.**—Apply in time Ferry, Winchmore-hill, London, N.

NAMES OF PLANTS AND FRUITS.

Names of plants.—*Cornubia*.—Evidently a form of *Rhododendron Nobileanum*. —**H. Munro**—*Saxifraga verticillata*. —**James Scott**.—The common *Berberis* broom (*Ruscus aculeatus*). —**O'Donnell**.—Specimens insufficient. —**Maud**.—*Pestocia glauca*. —**P. B. S.**—The Sweet Alyssum (*Alyssum maritimum*) increased by cutting. —**Weston**.—The Spring *Saxifraga* (*Leucocjum verum*). —**J. C. Bloomfield**.—The variety you refer to is no doubt *Adiantum capillus-Veneris*. —**Fuendree**.—1, *Polystichum acuminatum*; 2, *Polystichum angulare Kitsonii*; 3, *Polystichum Filix-mas cristata*; 4, *Polystichum vulgare semilacerum*.

FRUIT.

PRUNING THE PEACH AND NECTARINE.

THE pruning of these may well be undertaken in mild weather, though where surplus wood has cut out after the fruit was cleared in early autumn very little will be required. In case this was not carried out at the proper time, these remarks will apply. I prefer to cut out unnecessary wood before the trees are taken down from the wall, as one can the better judge which shoots can be dispensed with. It should be the pruner's aim to keep the wall well covered with wood made the previous year, as this is on this, when well ripened, the finest quite are borne. Ill-ripened or badly-placed shoots should be cut out, also those that bore fruit last season, shortening to a wood-bud likely to form spurs close to the wall. After the pruning done, loosen the trees and wash every particle of wood with a good lather made of soft-soap and flowers of sulphur, using a soft hair-brush, such as painter's use, drawing the same towards you on the bearing wood so as not to knock off the flower-buds. If the wall requires repointing it should be done before training begins, but where the walls are wired, merely colouring will suffice, and in replacing the trees get all the main branches in position first, which should be equally adjusted right and left from the centre, so as to form a fan, which is the best mode or all stone fruits. Next lay in the young wood, which should be about 3 inches asunder, and no objection can be offered to covering old and bare branches with young wood, especially near the base of trees. In nailing or tying see plenty of space is left in shred or raffia, using no more nails than are absolutely necessary to get the branches in position. After the training is finished, clear up all rubbish and work up the border 2 inches or 3 inches deep, and remove the soil, replacing with fresh loam, a little lime or mortar rubble, wood-ashes, and bone-meal, all well mixed together.

J. M. B.

PEACH STONES SPLITTING.

I HAVE a cool Peach-house with four trees that ripen in succession. I found last summer that before the fruit was quite ripe it fell off, and that in nearly every case the stone was split and it was more or less mouldy. I should be much obliged if you could tell me the cause and the remedy through your excellent paper.—H. S. F.

[Some kinds of Peaches are more addicted to stone-splitting than others, though it happens sometimes in a variety not commonly given to that failing. To imperfect fertilisation of the flowers may be traced the origin of some such cases. Stone-splitting is not an outgrowth of indifferent health; indeed, the reverse is more likely to be the case. When Peaches are flowering it is never safe to trust to chance in the setting, for without being fertilised with their own pollen or with that of other flowers by the aid of a camel's-hair pencil, rabbit's tail, or something of a similar character, the fruit may swell away for a time, even to ripening, and then drop from premature softening accelerated by the unsound stone. In this condition the fruit sometimes

falls and appears ripe, but an examination shows that it is soft only on one side, the other being congested and hard. It is among the early sorts that these troubles most frequently occur.

In too rich borders some Peaches drop when nearing the ripening period, and if they remain until they can be gathered they invariably ripen some time before the remainder of the crop is ready, which the expert grower at once recognises as a symptom of stone-splitting. Freshly slacked lime applied in quantity sufficient to whiten the surface is a good remedy in such cases, giving it once or twice during the growing season. With trees that are over-luxuriant, root-pruning, lifting, and placing the roots nearer the surface correct more than the one evil, bringing with it the lessened tendencies to splitting of the stone. Overhead shade from other trees hinders proper ripening of the wood, and without this neither perfect setting nor stoning can be assured. Extremes of root-moisture or drought are both inimical to the progress of the tree's growth in summer, and should be as far as possible avoided, as also should strong doses of animal or artificial manure, because they stimulate an excess of vigour which is undesirable. With a comparatively new border and healthy trees clear water is all-sufficient. It is for older trees in borders fully occupied with roots and carrying heavy loads that feeding is necessary. Lime, however, may be given in small quantity with advantage to Peaches, as this assists the formation of the seed-shell or stone. Unripened wood caused from overhead shade, imperfect fertilisation of the flowers, or an absence of lime in sufficient quantity may, however, give the clue to the failure complained of. Carefully lifting the trees and replanting will correct grossness, the autumn, when the leaves begin to fall, being the most suitable time. A mistake that is often made is neglecting the watering of the borders and syringing the trees after the crop is cleared.]

FILBERTS.

A WELL-ORDERED garden is not complete without a few bushes, and it is not yet too late for planting. In making a selection include the Gosford and Pearson's Prolific, which produce many catkins more freely than some kinds. Any good garden soil will grow Nuts, and in planting allow a spare of 9 feet to 12 feet between each bush, choosing those having a clean stem of 1 foot or more, or else a thicket of suckers will persistently push up, and if not cut out annually the bushes soon get crowded and produce but little fruit. If planted now, defer any pruning until next spring, but established bushes should soon have their annual thinning now the tiny red or pink female flowers are to be seen, reserving as many twigs as possible having fruit-blossom on, neither must too clean a sweep of the catkins be made, as on the two depends a great deal what sort of a crop we get. Should the male catkins be few and far between, it would repay to cut a few twigs of the common hedge Nut and tie on the bushes while in flower. In

thinning endeavour to keep the centre of the bush well open, so that sun may ripen the growths, as Nuts bear on wood made the previous year. Any robust shoots should be cut back to quite half their length, this thinning to make several branches break out, which, if well ripened, cannot fail to have plenty of fruit-blossoms on next year. Branches inclined to cross each other should be removed, but if looked over each spring little of this should be necessary. A stock may easily be increased by layering in autumn and by cuttings prepared in a similar way to Currants or Gooseberries. It is best not to rely on seedlings, as they are liable to deteriorate. Nuts keep plump for a long time if placed in earthenware jars and a little sand placed with them after they are freed from their husks and thoroughly dry.

EAST DEVON.

THE BEST CURRANTS.

CURRENTS, more especially the black and red varieties, are grown largely for market, and are also in request in most private gardens. In most cottage gardens, too, space is usually found for a few Currant bushes. The white-fruited Currant, compared with the black and red varieties, is cultivated but sparsely. It is, however, useful for the dessert, and is also valuable for clarifying Red Currant jelly.

BLACK CURRANTS.—A great advance has been made, both in size of berry and length of bunch, among those introduced of late years, and there are now many sterling sorts of this description. Of these there are Baldwin's Champion, a large-berried, heavy-cropping kind, good either for market or garden cultivation. This is also known and grown under the name of Carter's Champion in some localities. Lee's Prolific is another highly-esteemed Black Currant which bears heavily, the fruit being large and sweet. Then there are Naples, Ogden's, and Victoria, all worthy of cultivation, and a new kind named Paragon, or Boskoop Giant, is spoken most highly of, and should be given a trial. Black Currants prefer a moist, not a stagnant soil, such as a deep holding loam, and the site for them can hardly be made too rich. Plenty of well-rotted manure should be dug in and incorporated if the subsoil has not been disturbed or broken up for some time. Then trench the plot two spits deep and work a quantity of manure in with the bottom as well as the top spits. Once planted, all that is required is to keep the ground clean, well mulching the surface every winter so soon as the bushes have been pruned. Pruning consists in thinning out the heads of the bushes—i.e., removing the oldest of the wood after it attains full size, and shortening back any shoots that are too long. Never spur the young or side growths in, as with Red Currants, for instance, as the crop is always produced on these. By cutting out a certain proportion of the old wood annually and by keeping the roots in an active condition, the bushes will then be always well furnished with vigorous fruitful wood.

RED CURRANTS.—Among the red-fruited kinds American Wonder is a very large new-

berried sort that stands high in the estimation of market-growers in the West Midlands. It is a vigorous grower, bright red in colour, and flesh firm, which renders it a good traveller. Raby Castle is still one of the best for general use, the bunches being very long, berries large, dark red in colour, and hanging and keeping in good condition till late in the season. This is one of, if not the best, variety to grow on a north wall for very late supply. Cherry, also known as La Versailles, is an exceedingly large Currant, and is, moreover, very prolific. Where large quantities of Currants are required for cooking and preserving, this is the best kind to grow. Comet or Fay's Prolific is another large fruited kind, the bunches being unusually long and the fruit not so acid as that of the Cherry. This is an abundant bearer, and should be in every garden. Red Dutch or Grape is a very prolific old variety, but does not compare with any of the foregoing for size of berry or length of bunch, and is not now so largely planted as formerly. The two best white kinds are White Dutch and Transparent, the latter being, if anything, the finer. Current of the two, and more handsome from the fact of its semi-transparent skin disclosing the seeds and becoming quite a golden colour when fully ripe. Any ordinary garden soil, providing it is enriched with manure, will suit Red and White Currants, and it always pays to treat them liberally in this direction after they are once established, when they continue to yield heavily for years. I once had a break of Raby Castle that had occupied the same site and bore continuous crops of fruit for nearly twenty years. The pruning of these varies considerably from that of Black Currants, inasmuch as once the bushes are properly furnished with main branches, all side shoots must be stopped to form spurs, and when this has been accomplished, the growths emanating from the spurs should be cut back to three or four buds every winter. A little more latitude may be allowed with regard to the shoots issuing from the ends of the main branches, as, if it is desired to extend such branches, they may be left one-half or two-thirds their entire length. It is also good practice to remove an old branch now and again and to train a young one in its place, this keeping the bushes in a healthy condition.

A. W.

NOTES AND REPLIES.

Watering fruit-trees under glass.—When should fruit-trees under glass not have water?—FRUIT.

[There is really no set time when fruit-trees under glass should not have water. Very much less is, of course, required during the winter months when the trees are resting, but even then no good cultivator would hesitate to apply it if he found his borders were approaching dryness. As a rule, borders, if properly constructed, will remain in a moist condition from two to three months in the depth of winter, but it is far the best and wisest plan to ascertain their condition every few weeks, and to act accordingly.]

Pruning a maiden Peach-tree.—I bought a maiden Peach-tree last autumn, and have not yet pruned it. It has four fan-trained branches about 3/4 yard long. Should I shorten them in March, and how much?—F. M. G. P.

[As vegetation is in a forward condition, you may prune your maiden Peach-tree at once. With regard to the distance to which each branch should be shortened back, it is good practice, when the shoots on a maiden Peach are vigorous and the wood well ripened, to merely tip them, and to lay them out in a nearly horizontal or oblique position (which leaves the centre open), and then the shoots break throughout their entire length, which enables the grower to quickly clothe his tree with branches, and a whole season's growth is then gained. Seeing that the branches on your tree are but 18 inches in length, and therefore, we fear, but weak in growth, we would advise you to shorten them back to within four buds, counting from the base of each shoot. These buds, when they break, will supply you with plenty of shoots with which to lay the foundation of the tree this season.]

Pruning fruit-trees.—I have three Peach-trees (Royal George and Hale's Early) that I planted in December last on the wall at the back of an unheated lean-to conservatory, with a view to training them up the wall

(12 feet by 20 feet). How and when should I prune? They are nice fan-shaped trees with some six rods about 4 feet long on each. I have also some standard cooking Pear-trees and Victoria Plums planted in the open in December. How should these be pruned? The Pears have a stem about 4 feet, and then four or five good branches about 3 feet long coming out at the top of the stem. The Plums are on stems about 5 feet high, and have a little nest of weak branches at the top.—BURLING.

[If the growth of the Peach-trees is of last year and has reached a length of 4 feet, the tree is very vigorous, and probably would have few fibrous roots and a tendency towards those of a thong-like nature. If this is so the trees would repay somewhat more severe pruning so as to cause them to break from near the base, which they would not do well if lightly pruned. Should this not be the case the shoots could be shortened to about one half their length. The principal object in dealing with young trained trees is to first get a good foundation, and once they are established and growth becomes more free prune less and tie in the shoots, in some cases without shortening, in others with only moderate pruning. Disbudding and summer pinching may be made the better means of control, as by pinching the vigorous shoots the weaker ones gain an advantage. Many good gardeners find that standard trees are best left unpruned the first year, except so far as thinning-out of those branches that are crowded. The stronger and main shoots are, when left unpruned, a support to the roots, and help to set up a freer root action. Once they have become well rooted, pruning may be modified to suit the tree. If they were not of good shape some would cut them back to, say, 1 foot from the point of issue, and by these means a well-balanced head may be set up. Much depends on root treatment. They do not need manure if good fresh soil, a little burnt refuse, and leaf-mould can be used at planting time.]

Liquid-manure for fruit-trees.—When may this be applied to Peaches, Nectarines, and other wall fruit-trees, either under glass or out-of-doors?—FRUIT.

[Your query opens up a wide question, as liquid-manure is not, we fear, used to anything like the extent that it might be, neither during the growing season nor in the winter months. Provided the drainage is good and the trees fully established, Peach and Nectarine-trees under glass are greatly benefited if the border is thoroughly moistened throughout with liquid-manure, diluted little or much, according to its strength, during the winter, and in the case of a late house this may yet be done. As a general rule, winter applications are best given while the trees are at rest, either in or outdoors, say, during the latter part of November and any time in December. Outdoors you may use it in the winter season for old but healthy trees of Peaches, Nectarines, Plums, and Pears on walls, the two latter fruits out in the open, also Apples, Raspberries, and bush fruits of all kinds, with excellent results. During the growing season liquid, diluted as advised, may be used under glass after Peach-trees have set their fruits, but they will derive the greatest benefit from its employment after the fruits have stoned, when it may be applied whenever water is required at the roots right up to the time the fruits are about to ripen. Figs also come under this category, and in their case it is best to wait until the fruits are taking what is termed the last swelling before applying it in liberal doses. You may also use it during the growing season outdoors for the kinds of fruit already named, with Apricots added to the list, from the time the trees swell off their crops till they are nearly ripe, at the same time remembering in the case of stone fruits that it is safest and best to apply it in larger quantities after the stones have set than before.]

Planting fruit-trees.—If one wishes to plant a garden or a wall with bearing fruit-trees it will cost a deal of money, but young trees may be purchased very cheaply if bought in quantity, and anyone having room might buy the stocks and work his own trees, or, if he did not care to do that, maiden trees might be bought in at a cheap rate, and be planted either in a nursery bed or thinly round or across the vegetable garden, and they would, without costing anything for their keep, be growing into money. In this matter of fruit-tree planting there is much delay—so much waiting till the old is removed before planting

the new. The same thing should be done with wall-trees. Wherever there is room for a young tree let one be planted, and the removal in two or three years' time will just give that check that will throw the tree into bearing.

Pear Bergamotte Esperen.—Five samples of this Pear came before the R.H.S. fruit committee at the Drill Hall on the 13th ult. They were evidently well grown, and from Ginton Park, Suffolk. Some time since efforts were made by some members of the committee to obtain for this Pear an award of merit as a recognition of its merits as a late variety. Although defeated, it was to them specially interesting to see it presented at so late a period in such fine form and of such excellent quality. The fruits were of medium size, broadly round, having moderately long stems, and fairly handsome. Many gardeners have shown this Pear well and speak highly of it. It is evident that it is well entitled to rank as a good late Pear with Winter Nellis, Beaumance, Easter Beurre, Josephine de Malines, and Olivier des Serres. Late Pears, as a rule, need wall culture, otherwise the fruits are apt to be rather disappointing.—A. D.

Apple Rymer.—I gathered last year a heavy crop of remarkably fine fruit of the excellent cooking Apple from an orchard standard. Although the past season has been anything but a sunny one, the majority of the fruits were well coloured, and exhibited that polished appearance which is characteristic of this variety. It is somewhat similar to Wellington or Normanton Wonder at first sight, but a close inspection reveals the fact that Rymer is slightly different in shape, and that it has a beautiful reddish-brown cheek—a depth of colour that Wellington never assumes—and a very short stalk. It has a yellowish firm flesh and sub-acid flavour, a sure indication of its cooking qualities, and is in season during December and January. It is a capital cropping Apple when grown as a standard in the orchard, the habit of growth then being spreading, and the crop is, therefore, not so liable to be damaged by high winds. The Apple also succeeds remarkably well in the Midlands, and I have on several occasions seen very highly coloured and fine specimens grown in the neighbourhood of Birmingham, and in a district largely affected by smoke. It is also known under the name of Green Cossing, but the above is the more popular one, and as such I have known it for the past thirty years as a first-rate cooking Apple.—A. W.

Currants on north walls.—It is the gardener's duty to prolong the hardy fruit supply, so that mixed dishes may be had over as long a period during the summer and autumn as the season will allow. This is best achieved by planting on late positions, and, while not claiming that flavour is quite so good as in fruit grown in the full sun, nevertheless, Currants and Gooseberries are very passable for dessert when favoured with hot, dry weather during the months of August, September, and October. I have known the Red Currant hang on well into November in Devonshire, but if not equal to dessert the fruit is most acceptable in the kitchen, and comes in useful to mix with autumn-fruiting Raspberries, Logan Berry, etc. Black Currants I have grown in this position, but the Red are more valuable, the Black unfortunately were dropping when fully ripe, but not so with the Red or White even. The White Currants are not so useful as the Red, neither are they so sweet, even when grown in the open quarter. Three or more shoots can be trained up, shortening back the leading shoot to about one-third its length at the winter pruning until the allotted height is filled, and keeping all side shoots spurred in as with those in the open. To keep these late fruits, netting must be put on soon after colouring commences, or the birds will sample them even ere you are aware of it. Currants enjoy a good, rich soil, so a top-dressing should be given yearly and lightly forked in after the necessary pruning and cleaning-up have been done, and if liquid-manure be applied while the fruits are swelling, and a mulch of straw stable-manure be given, fine berries, clean growth, free of red-spider, should be the result. Keep eyes that caterpillars do not get a footing, or they soon do a lot of harm.—EAST DEVON.

TREES AND SHRUBS.

CEDARS IN A THAMES VALLEY GARDEN.

The multiplicity of catalogues and fine names very often calls attention from the good old things. Half-hardy Conifers and their varieties, pyramidal, prostrate, and all the rest of it, things of doubtful good in various shapcs, have obliterated the handsomest Pine ever brought to England, and the Cedar of Lebanon,

in severe winds and snowstorms, which so often destroy it when standing by itself, it is much more likely to escape disaster. For shade in summer and shelter in winter there is nothing like it, and we hope it will never be neglected in garden planting of the best kind. Like most of the Pines, the Cedar of Lebanon is better planted young, although usually planted rather as a specimen—an expensive and not always successful way. Rabbits are very fond of the young plants, and it must be carefully protected where they abound.

Berberis Aquifolium (Mahonia), and the Tree Ilex. We fear Berberis Darwini and B. stenophylla would not succeed, as these prefer a lighter, sandy loam.]

Lifting Araucaria.—Would you kindly let me know the best time to shift an Araucaria? It is about 5 feet high, and I would like to get it shifted this spring if possible. When is the best time to cut Box edgings?—A. B. C.

[You ought to prepare your Araucaria now by digging a trench round it about 3 feet from the stem and filling in with some good loamy soil to which has been added plenty of leaf-mould. This will encourage fibrous roots, and then you can lift in the spring of 1904. Be careful that you have a good ball of soil when lifting, as otherwise failure will follow. You ought to keep it well watered until the young roots have got a hold of the fresh soil. Cut your Box in April.]

PLANTS AND FLOWERS.

CHRYSANTHEMUMS.

EARLY-FLOWERING CHRYSANTHEMUMS.

SEASONABLE WORK.

It is a mistake to insert the cuttings soon after the plants have ceased flowering in the late autumn. Much better results may be obtained by encouraging the old stools to produce a quantity of nice healthy and stocky growths by the second or third week in February. To achieve this object it is important that some of the old stools should be lifted and plunged in some light and gritty compost on the greenhouse bench; or, failing this, a cold frame may be used. In the latter case the development of the new shoots will not be so rapid as in the case of those placed in the cool greenhouse; nevertheless, advantage may be gained by either method. I propagate the early sorts from the end of the second or third week in February and many succeeding weeks. The increasing length of day as the month progresses is important. Cuttings put in during the dull and dark days of early and mid-winter must of necessity remain in a somewhat dormant condition, and the quality and condition of the cuttings, too, cannot be nearly so good as in those developing later, when the plants have regained the vigour which was lost during their flowering period. The flowering must tax the constitution of the plants, and unless ample time be given to them to regenerate it seems unreasonable to expect them to do well in the succeeding season. These early-flowering varieties do not want codding. The cuttings may either be inserted in shallow boxes

Cedars of Lebanon in Thames Valley garden. From a photograph sent by Mr. P. Hargreaves, 18, Dean Street, Hammersmith.

NOTES AND REPLIES.

Evergreen shrubs for clay soil.—I should be much obliged if you would give me a list of evergreen shrubs likely to grow on a smoky and draughty site? Our hospital buildings lie north and south, and there is a very strong current of air between them in windy weather. Some of the borders are large, 30 feet to 70 feet long, and 20 feet to 30 feet wide. We have a large number of deciduous flowering shrubs in them, but they look so bare in the winter that I wish to introduce more evergreens. The soil is a poor heavy loam over clay, but we have plenty of stable-manure and old road-sweepings. Would Tree-Ilex and Box-trees do among others? I should like to use Berberis Aquifolium, Darwini, and stenophylla, but am doubtful if they will stand the bitter wind.—M. A. B.

(Among suitable plants for your purpose we would recommend Deubaa, Hollies, Box, Cherry Laurel,

containing loam and leaf-mould in equal parts and plenty of coarse silver-sand, all having been passed through a sieve with a rather fine mesh, or they may be inserted around the edge of 3-inch or 5-inch pots. Where a large number of plants is required a kind of shallow trough may be made up on the greenhouse bench, not far from the hot-water pipes. This trough may be made of a length to suit the requirements of the propagator, and if the compost be filled in to the depth of about 3 inches it will answer the purpose intended very well. The cuttings should be dibbled in in rows, and as each new variety is taken in hand a label with

like some other good old things, looks as if it were out of fashion now, owing to the many new things offered in the shape of trees. Here is a tree which after trial of two hundred years is as happy in our climate as in its own. We exempt the town, and yet it makes a hard fight in both Paris and London, in spite of the smuts; but in the open country no native tree is happier. In gardens generally it is too much grown as a separate tree, although its finest effect is, we think, in such a group as is shown in our illustration. Where it has the companionship of its own kind, and is held together as a group, its shade and dignity are no less and

its name should be put in, and thus avoid confusion. A distance between each cutting of about 2 inches, and slightly less than 3 inches between the rows of cuttings, is sufficient. Each cutting should be about 3 inches long. Cut through with a sharp knife, and trim off the lower leaf close to the stem of the cutting. Make a hole of sufficient depth to embed the cutting to the second joint. Before making the hole, sprinkle some silver-sand on the surface of the soil, and by these means ensure a small amount of sand being carried down to the bottom of the hole on which the cutting should rest. Press the soil firmly around the base of each cutting, or it may be left suspended in the hole, and, in consequence, is sure to damp off. There is no need to cover the cuttings with glass. With the temperature maintained at about 45 degs. to 50 degs., the cuttings should be nicely rooted within three weeks. In a few special cases the time may, perhaps, be rather longer. During the rooting, when the soil becomes somewhat less moist than is considered desirable, it is well to give another watering, and an occasional sprinkling overhead when the surface soil is dry is also an advantage. The propagation of the early sorts may be continued right through the spring and until May, or even later. C. H. N.

Chrysanthemums—sturdy plants (*Chrysanthemum*).—We are disposed to believe the reason for your plants being weak and drawn is because you fail to ventilate your cool greenhouse satisfactorily. It is not necessary in their early history to treat the plants to the "air-tight" method which you adopt. This in itself is undoubtedly the beginning of the trouble, and although you have no artificial heat, except on frosty nights, there are periods of bright sunshine at intervals during the day which increase the temperature very considerably. Under such conditions the young plants become drawn and weakly. The soil when first repotting the young plants should be firm. The greenhouse should, at all times, be freely ventilated, taking care, of course, to avoid draughts. The young plants, too, should be arranged on shelves as near to the glass roof as possible. It would be far better, however, to transfer the young plants to cold-frames, where a far harder and more sturdy character of growth may be encouraged. This is what you should strive after, and if you are without a cold-frame you would be well advised to procure one without delay. Plants in cold-frames can be kept up near to the glass, and air is easily afforded. Just a "crack" of air, or a very liberal supply may be given, according to the weather. The varieties mentioned in your letter represent several of the taller sorts, and on this account you cannot very well expect to raise from them a batch of sturdy plants. As there are so many excellent dwarf to medium plants possessing a sturdy habit of growth, and these, too, capable of developing blooms equal in point of merit to those mentioned in your query, we should be disposed to acquire a collection of these more suitable kinds. We shall be pleased to give you a selection if you desire us to do so.—E. G.

OUTDOOR PLANTS.

NOTES AND REPLIES.

Plants for filled-up pond.—Will you advise me as to the best way of planting a cleared space—a filled-up pond—in the middle of a belt of high trees? What sorts of evergreens, Ferns, bulbs, etc., so as to have a screen of shrubs with a carpet of flowers?—E. T. MARSHALL.

[You cannot do better, if the soil is composed of leaf-mould, than plant *Rhododendrons*, hardy *Azaleas*, intermingling with these any of the *Liliums*, such as *L. superbum*, *L. pardalinum*, &c., with *Epilobium*, *Spiraeas*, &c. Among Ferns any of the hardy varieties will answer, including, of course, the Royal Fern (*Osmunda regalis*), while you can plant *Daffodils*, *Snowdrops*, &c., along the edge.]

Flowers in February in the Thames Valley.—The mild weather has brought the flowers a little earlier, not so much on the cold and windy hills and clay flats as in the Thames Valley, from which Messrs. Barr at Long Ditton send us a large collection of their alpine and early flowers, including several

varieties of hardy *Cyclamens* very pretty in colour, various wild *Crocuses* like *C. Tommasianus* and its forms, some early Eastern *Iris*s and *Scilla taurica*, and a very handsome lot of Lenten *Roses*, *Helleborus*, early *Heaths*, *Primroses*, *Hepatica*, and two *Daffodils*, cyclamineous and *minimus*. These ought to show us that in a good collection of hardy flowers beauty is hardly ever absent nine months out of the twelve.

Raising Primrose.—Will you kindly tell me how to raise *Primroses* in quantity for a thin wood in my garden? For two years running I have sown seed, the first year in boxes in a frame, the second in the open ground in the end of April, and it did not come up. This was the common *Primrose*, but *Japonica* failed also. I grudge robbing the woods.—HALLGROVE.

[Be sure your seed is good, and sow in April in leafy soil on a shady border. You may also, as soon as the seed is ripe, which generally takes place about midsummer, sow in boxes or pans, planting out the seedlings in the open ground, and thus having strong plants to flower the following spring. We think you would be more successful with the garden *Primroses*, good seed of which can always be had in the trade. *Primrose* seeds have very hard cases, and should the soil become at all dry, failure to germinate is sure to follow.]

A summer garden.—Will you give me some ideas for a new piece of walled garden I am converting from a kitchen one into a summer flower garden? It will open by an arch into the rosary. It is to have a sundial in the centre. Masses of colour together are wanted, but the corner beds seem too large for one thing. Green angles where plants are wanted coming out of the Grass. There is a border at east side, 70 feet by 10 feet, water filling, Box as a background. I want it quite a summer garden—no *Phlox* or *Michaelmas Daisies*, *Dahlia*s, or those sort of autumn things.—M. S.

[Read the chapters in the "English Flower Garden" on the "Summer Garden Beautiful." Plant Monthly and Tea *Roses* and the best of the half hardy bedding plants. In the corner beds you could have groups (say six or twelve plants) of the best of the Tea *Roses*, with an undergrowth of Tufted *Pansies*. *Carnations* also would answer well.]

Sowing lawn Grass seed.—I have a piece of ground 108 square yards, which is intended for a lawn. It has been well dug over and rolled and levelled, and laid open all the winter. Can you tell me how much Grass seed I ought to get for it, so that I may have a respectable looking lawn this summer? Any hints as to making the lawn will be acceptable. Also, would March be too early to begin, the climate here being somewhat mild? Thanking you very much for your helpful answer a week or two ago.—C. W., Worthing.

[No doubt, in your comparatively warm district, you may sow Grass seed for a lawn so early as March, but generally April is soon enough. You should obtain 2 lb. of lawn seed, and in ordering state whether your soil be light or heavy, loamy or chalky, that you may have Grasses suited for the soil. Before you sow, assuming, as you say, that the soil is settled and well levelled, stir the surface with the point of a fork, or else with a long toothed iron rake, then sow the seed with the greatest care when the weather is quiet, so that it falls on the ground perfectly even, then lightly rake over and well roll it in. Birds must be kept from scratching and eating the seed. Growth should follow in a week, and in a month you should have a thoroughly green lawn. The first mowing should be with a scythe.]

Dividing hardy plants.—I have beds and borders of *Saxifraga Wallacii*, *Tiarella cordifolia*, *Arabis*, etc., that have grown very straggling and untidy, not having been divided and replanted during a long absence from home on my part. When is the best time to lift and replant under these circumstances?—MAIDENCOMBE.

[All of the plants named by you may be taken in hand at once. The *Arabis* and *Saxifraga Wallacii*, indeed, submit to division and replanting at any time during early spring: the *Tiarella* likewise, though in this case being, in some few instances, inclined to send up quite early in spring its flower spikes, it is advisable to take this plant first in hand. You will find little difficulty in increasing it, but we may warn you not to cut through the tufts in any haphazard way, as, owing to its mode of rooting and growth, a large number of root fibres may in this way be sacrificed. By lifting the clumps and washing away the soil, you will find that it is easier to pull this plant to pieces than to attempt to cut it up. We strongly advise the former mode, and if the short rhizomatous growths are firmly replanted, you have done the best possible. In certain instances the young outlying shoots root freely, and this may be so in your old established plants. But at any time when March is with us

you may start, and the sooner the better. The other plants are less difficult to please in this matter, and may be taken in hand almost at any time.]

Californian Bush Poppy (*Romneya Coulteri*).—I wish to plant the Californian Bush Poppy (*Romneya Coulteri*), but as the plant is reputedly tender, I should be glad if, on hearing of the results of the year, you would tell me if it would be likely to succeed? The soil is light, warm, and of fair depth (about 2 feet), inclined to be gritty, and well drained. Its one fault is that it does not retain the moisture well enough during periods of drought, but this is provided against by deep trenching, a layer of manure well down in the bottom, and surface mulching. *Phloxes* have succeeded remarkably in it. *Roses* do well with an admixture of somewhat stiffer soil, and Sweet Peas bloomed continuously until October, both during last summer, which was wet, and the summer before, which was dry. The position intended for the *Romneya* is a bed of irregular outline (all my wall space is filled up) facing south, but not receiving the sun until between 10 and 11 o'clock at this time of the year. It is about 12 feet across in its widest part, and of a similar measure in the perpendicular direction. It is well sheltered on the north and east by high banks, topped by thick hedges some 10 yards distant, but exposed to the north-west wind, the prevalent current here during the winter. The climate is, however, very mild, the sea being about four miles off. It is a rare occurrence for the mercury to fall more than 4 degs. below freezing point. That has not happened yet this winter, and only on one occasion was it down to the 28 degs.—ROMNEYA.

[We see no reason why the *Romneya* should not succeed. It is quite hardy in general soils, enjoying best a warm loam. It does best on warm soils in different parts of the country, so that no one need doubt the fitness of this noble plant for English gardens. The best winter protection is a mulch over the roots of some light porous material, such as Cocoa-nut-fine. During very hard frost a mat may be placed over the branches, but this should be removed as soon as the weather becomes less severe.]

Manuring flower border and *Roses*.—Will you kindly advise me as to the above? The soil is dry. The herbaceous lawn south bed so far I cannot do in top-dressing every season, and I fancy it may be better this spring to give it some artificial manure. What does advise? The *Roses* are in a long bed by themselves. Can I put bone-meal or nitrate of soda down the centre between the rows, forking it in? I want you to advise me to use that manure which will give the best results, and it is because the herbaceous things are so close that I think they will possibly do better if I can feed them well. I find most things do well here, especially *Roses*, and I have all the best kinds, though my garden is small, but I love every inch of it, and enjoy your paper immensely every week.—(MRS.) J. W. EMERY.

[One very important item is omitted—viz., the length of time since the *Roses* and other things were planted. Usually in soils of a clayey character the roots run deep, and the ordinary surface mulch accorded freely to the lighter classes of soils would avail but little in this case. We therefore advise that for the herbaceous plant border a dressing of air-slaked lime be given at once, sowing it thinly between the plants and not too near the crowns. If any difficulty is felt in obtaining the lime, a good dressing of soot may be given. Sow on the surface in each case and lightly point in with a fork. This should be done before mid-March. A month later another dressing may be given from what is recommended hereafter. Obtain 1 cwt. each of bone-meal, kainit, and blood manure, mixing thoroughly together, and then add three barrowloads of comparatively dry potting soil. Thoroughly incorporate soil and manure in one heap by several times turning over, and place in a rather dry shed. After two days this mixture may be used as a top dressing for all your beds. The above quantities would afford three liberal dressings for April, May, and June. If possible, apply the dressing before rain, and if rain does not quickly follow, then wash in the manure with a heavy watering from hose-pipe. The *Roses* and herbaceous things may all be liberally treated, and if in July you could apply a liberal soaking of liquid stable manure you should have the success you desire to obtain.]

Godetias.—*Godetias* are not grown nearly so much as they ought to be, considering how full of blossoms, ranging from pure white to the deepest crimson, they are for weeks together. They are particularly adapted for growing in masses, and I recommend them to the notice of those whose garden soil is poor. *Godetias* give a better display in a town garden than most annuals, and if each plant is given sufficient room to grow, then one may expect a good display. Seed may be sown in the open air in April, thinning freely when the plants are large enough to handle.—TOWNSHEND.

PRIMULA FRONDOSA AND OTHERS.
 THE excellent illustration that accompanies these remarks shows a group of this alpine Primrose, providing an object lesson in the free grouping of alpine flowers that is worthy of

The Bird's-eye Primrose (*P. farinosa*).

widest part only 3-inch broad. The margin is distinctly notched. The whole plant is covered with a thickish meal or farina. In the winter season all that is visible of this pretty-eyed species is a few imbricated mealy buds on the surface, that in the older plants cluster together quite closely. The yearling crown may give but one spike of flowers, but, with this flowering over, as many as three or six crowns may be seen, each of which will flower later in the year. Thus it will be seen that this gem alpine is also a good perennial; indeed, it may worthily be classed among the best alpine Primulas. The plant succeeds quite well in rich loam with plenty of grit and sand, and a free supply of water during the season of growth. Some plants in loam, old mortar, and fine charcoal have made splendid headway of late, and plants having many crowns are the result of a let-alone policy.

P. FARINOSA (Bird's-eye Primrose).—This is one of the most dainty of all Primulas, growing some 6 inches or 9 inches high, and producing blossoms of a lilac colour with a yellow eye. Seedlings vary occasionally in colour, and tints of pink and rose are frequent and pretty. The blossoms are rather less in size than in *P. frondosa*, and the leaves more silvery, perhaps. There is much in common, however, between the plants.

P. SCOTICA.—This is a dwarf or miniature *P. farinosa*, so to speak, but it is a stout and sturdy plant, notwithstanding the 3 inches or 4 inches that it attains. It is an exquisite

soil need not be sandy. Any good fibrous loam, with a little manure finely sifted added thereto, will do quite well. Make the soil moderately firm and level, and use pots, say, 7 inches or 8 inches in diameter. These may be filled nearly three parts full of the soil, and at this level the seeds may be thinly placed. It is important in the raising of these plants from seeds that the pots be sunk in the water sufficiently deep to just cover the seeds, hence the reason for not tilling the pots with the soil. As the seedlings appear—and in the case of *N. Lotus*, *N. L. dentata*, and *N. corulea* it is but a question of weeks—the pots may be sunk a little deeper in the water, and with the appearance of second leaves pot them off singly into pots 4 inches across, using rich loam and manure. A tank placed over the hot-water pipes would answer quite well for the seed raising, or shallow pots or pans placed inside much larger ones would do equally well, inasmuch as all would be under control. The larger pans would require to be perfectly watertight. The three kinds named above may be flowered the first year if grown quickly and allowed to suffer no check. Of these three *N. corulea*, which is synonymous with *N. stellata*, may be grown in the open after June in tanks where the water is warmed, and quite a number of plants may be accommodated in a tank 6 feet square. The other kinds, *N. Lotus* and *N. Lotus dentata*, must be grown indoors, though even in their case it is but a question of a right temperature and quick growth to make them flower in the first year. For these kinds water heated to 70 degs. will be ample, and with a house temperature similar no difficulty should be experienced. The other kind, *N. alba*, is quite hardy and must be treated accordingly, placing the seed-pans in the water in the open air and observing conditions akin to the above. This kind you will not flower in the first year and probably not before the third year, when a rhizome of good size should be forthcoming. When of this age the roots should be given permanent quarters in at least 2 feet deep of water, and with a bushel or two of soil to start into. The former set may be dried off somewhat in winter—that is, the temperature lowered and the water drained away gradually, never permitting the roots to become quite dry or subjected to a lower temperature than 40 degs. This may be done each year and kept up for three months or more. As to space required, *N. Lotus* and *N. L. dentata* are large-leaved kinds, and send their leaves far and wide where opportunity is afforded. At the same time a good flowering may be secured in a way similar to that for *N. corulea*; indeed, the great essential to quick development and an early flowering is heat and water, as already stated. A tank 2 feet in depth will answer, and if possible to arrange for a circular tank in the stove, no better place could be given. The following are all hardy kinds of the colour you wish for: *N. odorata*

imitation. We note some miniature growing alpine plant in blossom, and see all the beauty it reveals by a close inspection, but in the majority of instances no adequate measures are taken to reproduce the one great essential of all alpiners in their mountain home—viz., a free, natural grouping in colonies and the like.

An alpine Primrose (*P. frondosa*). From a photograph sent by Mr. H. S. Fish, Edinburgh.

How suitable is *P. frondosa* for this method of grouping the picture shows, and in turn proves also that the species is easily raised from seeds. In certain of the smaller growing class of alpiners, and in the species of Primulas in particular, the raising of the plants from seed is by far the best method of increasing the stock. Indeed, it is only in this way that a flowering group such as is now seen could be produced. Seeds, therefore, are of the greatest value, and should be preserved in every instance, if only for the rapid increase of any one kind, and more especially on account of the greater vigour of the young seedlings when compared with divided examples. Of those species producing seeds freely, dividing the old plants may be regarded as a waste of time almost, and it is not advised for the above, or even suggested as worth the trouble. Seeds are abundantly produced and young plants easily raised. In the same category with the above-named kind are two other species that for all practical purposes may be treated in the same way. These are *P. scotica* and *P. farinosa*, and the three constitute a most pleasing set in any rock garden where they are treated with a generous hand.

P. FRONDOSA.—This attains to 6 inches high, or, perhaps, rather more occasionally where soil and other things are favourable to its well-being. The blossoms are about 1/2 inch across individually, of a pale lilac, and sometimes a rosy-lilac hue is seen in the younger flowers. The leaves, which are firm and thick for their size, are 3 inches or 4 inches long, and in the

species, and when in flower, colonised as it should be, it forms a sumptuous array of rich purple that the yellow eye but renders the more intense. It is a true British mountain plant, found wild in damp pasture land in the north of Scotland. This fondness for pasture soil should not be lost sight of when the plant is under cultivation, and, in truth, the kinds named above all have a preference for rich, moist loam and of good depth.

In growing these Primroses from seeds it is well to sow them in early autumn, especially home-saved seeds. Where the seeds have to be purchased the present time is excellent, and with progress following a successful batch of seedlings, capital plants will be forthcoming during the season. It is advisable, periodically, to raise seedlings of these last two kinds, as in this way only is a good flowering group maintained from year to year. E. J.

Raising Water Lilies from seed.—I have some Water Lily seeds of the following varieties: *Nymphaea dentata*, *N. Lotus*, *N. alba*, and *N. corulea*. Will you be kind enough to give me directions for the raising of same? I shall also be glad to know how long it will be before they come to maturity, space that should be allotted to each sort, the habit of the plants, and if they will stand the frost? Can you also give me the name of a rose-coloured sort for growth outdoors?—A. L. PLUM-BROOK.

[Only one kind named by you, *Nymphaea alba*, is quite hardy; the others are tender, and *N. Lotus*, with its variety *dentata*, requires, to do you justice, almost a stove temperature. The seeds of all the kinds should be sown in the usual way in pans of soil, but in this case the

The Scotch Bird's-eye Primrose (*P. scotica*).

rosa, *N. e. rubra*, which is pure rose in colour, *N. o. rosacea*, fragrant, *N. e. exquisita*, rose-carmine. In the Marlene hybrids, which are the largest flowers, there are many richly-coloured sorts, *N. M. carnation*, *N. M. rosea*, *N.*

M. ignea, the last of a deep rose-crimson hue. If you could find room for more than one, we recommend the second and last named.]

CACTUS DAHLIA WINSOME.

This, which was given an Award of Merit by the R.H.S. when shown by Hobbies, Limited, Perchaun, on Sept. 23rd last year, is pure white in colour, with the exception of the faintest tinge of yellowish-green towards the base of the centre petals of the flower, and is the first incurved variety in this colour. The petals are long and of good substance. Every bloom is produced boldly above the foliage upon a long, wiry, stout footstalk.

Iceland Poppies.—These are very attractive when planted in groups in the borders, and their blossoms are delightful when arranged in specimen glasses. Their colours are white, yellow, and orange-scarlet. Seed sown at once in heat will provide plants, some at least of which will bloom in the autumn, and will winter safely on a sheltered border. Then, too, there are the alpine Poppies, with blooms similar to those of the Iceland Poppy, but having a greater variety of colours. These being dwarf are particularly suited for the rock garden. These also may be raised from seed sown now. Then one can not lose sight of the perennial hybrids, and the Giant Poppies, which range in colour from palest pink to deepest crimson, and from white to orange, and make a border quite showy, even when one cannot make much use of them when cut on account of their rather objectionable aroma. Who after growing them would care to be without the bright orange-scarlet blooms of the Oriental Poppy in June? Sometimes one needs bright colours in the garden. Poppies, I maintain, will meet such a want. The fear is lest one should overdo the thing in the introduction of glowing coloured flowers in the border.—W. F. D.

Panocratum maritimum.

—"A. E. K." asked on page 580 for information about the above plant. I fear there is but little hope of flowering this beautiful herb in the open, even in the warmest and most favoured spots in England. It is but rarely seen, and in the few gardens in which it is to be met with, which are those where rare and tender plants are made a speciality, it seldom or never flowers. I grow *Panocratum illyricum* and have seen the species in flower also in other gardens, but have never attempted *P. maritimum* on account of its generally unsatisfactory behaviour. Sandy soil at the foot of a south wall is most conducive to success in the case of the former, and from the nature of its habitat the same conditions should be the most suitable for the latter, but there is small likelihood of blooming it except under glass shelter.—S. W. F.

***Campanula persicifolia*.**—A correspondent drew attention a few weeks ago to the Peach-leaved Bellflower, but referred only to the original purple type and its white variety. Neither of these is, however, so extensively grown as the double white, a favourite flower, often cultivated in large quantities for cutting, the blossoms being very lasting. Two forms of comparatively recent introduction deserve especial mention, as they are far superior in every way to the older varieties. These are *C. persicifolia Moorhoimi*, with very large semi-double white flowers, quite twice the size of those of the ordinary double white, which often blooms well into the autumn, and Backhouse's variety, which bears single white bells of great size and whose flower-spike is sometimes nearly 3 feet in height. The culture of these is quite as simple as that of the older and less showy relatives.—S. W. F.

ROSES.

SEASONABLE NOTES.

It will not be too early to dig in the manure which was applied to the Roses in November. Less harm will be done now by the use of the spade among the plants. I do not favour deep digging among Roses at any time, especially where the plants are on Brier cutting or Manetti stock. If on own roots, and the plants are in a light soil, the spade should never be used among such. A far better plan to adopt is to remove a shovelful or two of the soil from about each plant, place some well-decomposed cow or pig manure in the cavity made, and return most of the soil. An annual application such as this will generally prove efficient if supplemented by summer feeding with liquid-manure.

BURIED BRIERS, both dwarf and standard, should now be cut back. The standard Briers are usually budded upon threolateral branches. All other growths are now removed, and these three shortened back to within 3 inches

side, and let both press their heel against the Brier simultaneously. After this treading dig up the alleys to admit air and sunlight. The ground trenched up for dwarf stocks will now be in workable condition for planting seedling Briers. Where it is found at all difficult to procure these, common Sweet Briers, planted out, answer equally as well for Tea and Hybrid Tea Roses. They should not be larger than an ordinary pen-holder. Set them out in rows 2 feet 6 inches apart, and use a dibber sufficiently long to prevent roots from curling. Do not attempt any work on the land when it is wet. Better far wait until the surface has dried.

CUTTINGS INSERTED in the autumn will be found considerably raised out of the ground. They should be carefully gone over and pushed down, so that their base rests on soil. Where land has not yet been dug, it should be at once ridged up ready for later planting in March. This is more especially necessary with heavy soils. I have planted out Roses end of March and early April, and they have succeeded remarkably well and flowered rather later than

Cactus Dahlia Winsome.

or 4 inches of the inserted bud. There is usually found a small portion of the Brier stem at the extreme end that has died back to the lateral branch. This dead stem must now be cut out, taking care to have a sharp pruning saw and secateurs for the purpose, also smoothing over the jagged edges with a sharp knife. The dwarf Briers budded with Teas have their tops trimmed back right to the base, and finally cut back close to the bud at the end of March or early in April. This prevents the buds from starting, to be ruthlessly cut back by frost. When the buds are cut back, shallow digging down the alleys should be performed. Do not expose the buds more than can be helped. If the soil is turned on to them they will not suffer, provided it be not a heavy clod—in fact, the buds are much better covered up until May. They will probably push through the soil, but should a heavy frost cut them back the base buds will be safe.

STANDARD BRIERS planted this last autumn will need securing by pressing the heel against the Brier. It is a good plan for two diggers to perform this work, one on either

the established plants—consequently of much value on that account. Planting may now be done with every prospect of success. All who have missed adding to their Rose garden the many lovely decorative kinds now so popular should do so at once. Kinds like Mme. Abel Chatenay, Mme. Jules Grolez, Killarney, Coralline, Caroline Testout, Mme. E. Bouliet, Mme. Antoine Mari, etc., should be found in every collection, not as single specimens, but in groups of three, five, or more, according to space available. I would also recommend the planting of some of the charming dwarf Teas, Chinas, and Polyantha Roses against any odd bits of wall space available. Princesses de Sagan I have seen 3 feet to 4 feet high in such a position. Naturally, a south or west aspect should be chosen, and good soil provided and thoroughly drained. I think we often make a mistake in planting the rampant growers when those of more moderate vigour would be more suitable. If we can in a few years have a Marie Van Houtte, Safrane, Anna Ollivier, Souvenir d'un Ami, etc., covering a wall, 7 feet to 8 feet high, why is it necessary to plant Mme.

Berard and the like, merely because of a quicker growth? In planting Roses for pergolas at this season of the year, and where response is no object, I would advise pot grown plants for the purpose. These have usually growths some 6 feet to 10 feet long, and need not be pruned back, as is the case with plants from the ground, for the ball of earth will enable the plants to support this growth. Crimson Rambler planted in this way does well the first season. I would also commend to landowners the desirability of planting hedges of Roses about their estates. Surely, if we can do anything to add to the beauty of the landscape at a trilling cost it is a worthy act. I believe we are far behind our American friends in this respect. I have been informed that it is not at all unusual to find a hedge of Crimson Rambler by the public highway. I should like to say a word relative to the Wichuriana Roses as ornamental plants in our gardens. I mean not merely as trailing ramblers, but in pillar form. Plant one against an iron or wood pillar and allow it to gracefully droop over, and I can promise anyone who plants such, a very beautiful and elegant column of growth. Something might be invented for these Roses in the form of a draped column, so that the growths may hang gracefully downwards after attaining the required height. As weepers huddled on tall stems they make perfect and beautiful objects.

ROSA.

NOTES AND REPLIES.

Feeding Roses in pots.—I read with much interest your excellent article on "Roses under glass," by "Flint." Should be glad of further information as to whether and when manure-water should be applied to established plants in pots in a cold-house. I have some two dozen (mostly Teas) bought at a sale from private gardens recently, and they have now been pruned and are starting nicely. Growth is 2 inches long in some cases. Your advice will be much appreciated.—E. U.

[If the pots are well filled with roots you can give liquid manure weak and often as soon as the buds have formed, withholding when you can see the colour to the buds.]

Pruning Roses planted last November.—Last November I planted about a dozen roses of various kinds, chiefly climbers, H.P.'s, and H.T.'s. Up to the present all look healthy and strong. I have used methods of protection as suggested at various times in your paper, but I read further that I should prune them about March. Is this really necessary, except in the case of weak or "dead" buds, as they were considerably cut back when planted? Thanking you for many things learned already.—F. M. H.

[March is the best month to prune such roses, pruning them rather hard—that is, cutting the growths back about half way and thus laying a good foundation. Next year cut out only the weak wood. In the case of the climbing roses one shoot should be selected each year and cut hard back to the ground, thus insuring a constant supply of new wood from below, and thus the baroness at the bottom, so often seen in climbing roses, is avoided.]

Roses for pillars.—Please give me the names of eight good hardy roses, suitable for pillars 6 feet high? Soil is good, also situation, except that it is a little exposed to wind. There are only four pillars, and I would like two of contrasting colours for each pillar, or one good summer flowerer, such as The Garland or Longworth Rambler, and one autumn flowerer.—S. S.

[We should advise you to plant alternately a Rambler rose and one of the Tea, Noisette, or Hybrid Tea tribe, so that your pillars would not be entirely devoid of blossom in the autumn. The frost-growing and hardiest of these latter tribes are Reine Marie Henriette, Gloire de Dijon, Mme. Alfred Carriero, Souvenir de Mme Joseph Motral, Jeanne Desprez, Marie Robert. Revo d'Or, Climbing Devonians, and Climbing Kaiserin Augusta. Victoria are wonderfully vigorous, but, we fear, not sufficiently hardy for the position. Reine Olga du Wurtemberg is a grand kind, but not very free as an autumnal. Six other excellent kinds that would clothe the pillars but would not reach far beyond are Longworth Rambler, Mme. Brard, W. A. Richardson, Waltham Climber No. 1, Pink Rover, and E. Veyrat Hermanos. The best Ramblers for your purpose are Crimson Rambler, Aglaia, Thalia, Floro, Psyche, and Felicite-Perpetue.]

Roses for bank.—Why does not your correspondent, "Flint," try the new Wichuriana hybrids, such as Alberic Barbier and René André? These are crosses between R. Wichuriana and Tea roses, the first named having for parents R. Wichuriana and Shirley Hibbard, and the latter R. Wichuriana and

l'Idéal. Both these varieties have all the vigorous character of the Wichuriana roses, but far finer foliage and larger semi-double flowers. There are other varieties of these hybrids, such as Augusto Barbier, François Fouchard, Adelaïde Moullé, etc., which as yet have not made their appearance in the catalogues of the Rose growers of this country. This is quite a new class of roses, and for the rock garden, rough banks, and similar purposes simply superb. I strongly recommend "Flint" to give the varieties I have mentioned a trial.—M.

INDOOR PLANTS.

LINDENBERGIA GRANDIFLORA.

This pretty but uncommon subject was very noticeable among a group of plants exhibited by Messrs. James Veitch and Sons, Limited, at the meeting of the Royal Horticultural

Lindenbergia grandiflora.

Society on September 2, and visitors to Kew during the autumn and early part of the present winter may have noticed it in good condition in the cool end of the T range there. It is a plant of a sub-shrubby character, and of a somewhat straggling habit, which necessitates stopping when young in order to induce a bushy style of growth, in which condition it bears a considerable resemblance to some of the Salvias, though the flowers are a good deal in the way of those of the common Musk (to which, indeed, it is nearly related), but considerably larger. The colour is a clear, bright yellow, a very effective tint during the dull weather often experienced at its blooming period. This Lindenbergia is a native of the Himalayas, where it occurs at an elevation of 2,000 feet to 6,000 feet, and is in this country essentially a plant for the cool greenhouse. It can be readily propagated by cuttings of the young growing shoots in early spring, treated much as Fuchsias, Salvias, etc.—that is, given a gentle heat and kept somewhat moist and shaded till rooted. During the

summer it may be grown in a cold frame, or even outside. If the cuttings are potted off when rooted and shifted into larger pots when necessary, they will by the autumn be well established in pots 4 inches in diameter, and good for at least three months' flowering. Though it has been known to botanists for some years, this Lindenbergia is at present rare in gardens; but now that attention has once been directed to its merits it will soon be better known. T.

NOTES AND REPLIES.

Growing Chinese Primulas.—Will you kindly tell me how to grow Primula sinensis for conservatory to flower in December? I sowed seed last February, and scarcely any came up, and those that did come up never seemed to grow, and, not being worth keeping, were thrown away.—E.

[To grow Primulas so as to have a good display in November and December, seed should be sown in heat in February or March in boxes or pans of soil composed of loam three parts to two of leaf-soil, with a small quantity of silver-sand, keeping them in the house where the minimum temperature is about 55 degs. If a small hand-light can be brought into use it will be found advantageous to place it over the pans until the seedlings are large enough for pricking off, when thumb-pots should be got ready, potting again later when it is seen they are in need of a further shift. When potting use a little decayed cow-manure, or sprinkle a little guano amongst the compost, but cow-manure is to be preferred, as it is cool. Nothing is better for Primulas than a cool pit, where the plants may be stood on sand or ashes, and where shade may be given them during the middle of the day. Shade, as much as sunshine, is necessary for the ultimate success, and, of course, as soon as the weather permits in May the lights may be removed altogether until September. Almost before they are removed into the pots intended to bloom them in, which may be anything from 5-inch to 7-inch, according to the wish of the grower, flower-buds will show up at intervals in the summer, which should not be retained, as to do this would be at the expense of bloom in winter, besides weakening the plants. As the autumn approaches one should be prepared to give them stimulants. In placing them in position in the greenhouse it cannot be emphasised too much that a light position in the house where air may be unlimited is the very best spot one can assign them, and plants from seed sown in February and March will commence to bloom towards November, and keep up a good display until January or February.]

Asparagus foliage light green.—I have some Asparagus plants, but cannot get the foliage to assume the light green shade that is so much in vogue. I see in the shop windows some is almost yellow. Can you tell me how it is done, and what soil, heat, and feeding are required to produce it like that?—H. J.

[When in a healthy state the Asparagus is naturally of a pleasing light green tint, hence, to obtain this, it is necessary to keep the plants in good condition. A very suitable soil for the Asparagus is fibrous loam two parts, peat or leaf-mould one part, well decayed manure one part, and half a part of sand, the whole thoroughly incorporated together. The temperature required is a minimum of 50 degs. during the winter, rising to 60 degs. on bright days, with, of course, a corresponding increase as spring advances. Indeed, what is

known as an intermediate house—that is to say, warmer than a greenhouse and cooler than a stove—is most suitable to the Asparagus. Feeding should only be given when the pots are full of healthy roots, and then it must not be overdone. A pinch of some artificial manure, or a little manure-water about every three weeks will be sufficient. The long sprays that one sees in the better class shop-windows are usually obtained from planted out specimens—that is to say, a well-drained border is prepared for their reception, and good plants of Asparagus planted therein, the twining shoots being trained up strings, after the manner usually followed in the case of *Myrsiphyllum asparagoides*, popularly known as Smilax.]

Top-dressing plants.—I have in a bed in my conservatory, which faces S., but has no artificial heat except an oil-stove at night to keep out frost, two *Plumbago*, two huge Ivy Geraniums, an *Abutilon*, and a very large Asparagus Fern. The bed has been made three years, and I think, although the plants are doing well, that I ought to renew it a little. Would you kindly tell me how I should do this? I have at my disposal leaf-mould, loam, lime, and sand. I should add that at the foot of the climbing plants are three large common Ferns.—G. A. L.

[Clear off a little of the surface soil, being careful that you do not injure the roots of the plants in any way. Then mix the leaf-mould, loam, and sand, adding at the same time some rotten manure, and top-dress the border well with this.]

Arum Lillies.—Many who grow Arum Lillies lose sight at least of two important factors in their cultivation, and they are these: (1) Comparatively cool treatment; (2) a period of outdoor growth. It is, I think, a mistake to unduly force plants into bloom by placing them in a high temperature, which, so far as these *Richardias* are concerned, is likely to weaken them and make them an easy prey to green-fly, to which they are subject. I long since formed an opinion that planting in a shady part of the garden during the summer months, where they were fed with liquid-manure and liberally supplied with water, was the right course to pursue, as the plants which had been kept in the house were weak and puny in comparison. Those grown out-of-doors were reported in September and again brought under glass, being kept cool and free from frost until March, when they were brought into gentle heat and supplied with stimulants. The spathes produced from them were in every way superior to those on plants which had been kept in the house the year round.—WOODBASTWICK.

Pelargoniums.—It often happens when Pelargoniums are kept in pots in the greenhouse from year to year that they exhibit a leggy and altogether an undesirable appearance. This is brought about very often by their being mixed up with taller-growing subjects, and so they become "drawn." A few short, bushy plants are to be preferred to a number like those described, and should anyone possess plants that really ought to have been cut down last autumn, they will be well advised to bring the knife into use now. I have noticed invariably that whenever Pelargoniums have been allowed to get into this leggy condition the pots containing them have been covered over with that greenness which is a true indication that there is something radically wrong with the drainage. Plants in such a state should, in addition to their being cut back, be repotted, removing most of the old compost and shifting them into clean pots, using a little old turf, with leaf-mould, sand, and bone-meal, keeping them rather close for a few weeks until new growth takes place. Such plants, if stood out in the open in July and August, will give such a supply of bloom in the autumn as will astonish those who have been accustomed to look upon them as almost "having had their day." If, as suggested, cutting back is done at once, the cuttings which are worth retaining will root quickly with a little bottom-heat, and will doubtless be found useful for filling spaces in the borders in June and July rendered vacant by failures that will occur at times, no matter how careful one may be.—WOODBASTWICK.

Mimulus.—Although, strictly speaking, the well-known Monkey-flowers are perennials, they may be easily raised from seed and flowered the same year if sown in heat in March. *Mimulus* are hardy and bloom freely in the open air. It is, however, for indoor blooming that a sowing is suggested during the present month. Seed little more than

covered and kept moist in boxes or pans of very light soil will soon produce plants in a warm greenhouse ready for potting off in April. They are exceedingly showy, and must at all times be kept well supplied with water. Once let them get dry and their beauty is soon marred. They are, however, lovers of sunshine, and no doubt this is one reason why they do so well in rottage windows. *Mimulus* also form a convenient groundwork for standard Roses.—LEAHERST.

ORCHIDS.

ANGREECUM SESQUIPEDALE.

The illustration of this Orchid shows the plant when in flower last January in the gardens at Carton, Co. Kildare. The plant was over 4 feet high, with two growths, and carried ten spikes with 38 flowers. The thick, waxy flowers of this Madagascar Orchid, their ivory whiteness, and their extraordinary form are wonderful. The *Angreecum* are all epiphytal in habit. The specific name—sesquipedale—means a foot and a half, and refers to the long spur. The plant is grown at the warm end of the Orchid-house, with a night temperature not under 60 degs.

Angreecum sesquipedale. From a photograph sent by Mr. V. de O. Hughes, Carrygrane, Edgeworthstown.

by day; 65 degs. to 68 degs. during the winter months. In summer the temperature at night is 65 degs.; by day, 70 degs. to 80 degs. The potting compost consists of Sphagnum, rough crocks, and lumps of charcoal. The plant is never freely watered, but kept in a moderately damp state, not allowing it to get dry even in winter, although much less water is then required. V. DE O. HUGHES.

Coronilla glauca in small pots.

Since *Chrysanthomums* have become so popular this old plant has not been seen so much, which is to be regretted. The *Coronilla* blooms over a much longer period than *Chrysanthomums* and will bear the damp much better. This is of considerable importance to those with cold or only slightly heated houses. Few things are more ornamental than nice, small plants of this for placing in prominent positions, and especially for associating with Ferns, *Euonymuses*, *Veronicas*, etc. A good way to grow these small plants is to root cuttings in the autumn, potting them off early in the year. When the pots are full of roots pot the plants into 4-inch, 5-inch, or 6-inch pots, growing them in the open, in a sunny position, through the summer. When frost

sets in remove into a cold pit or house. These young plants will bloom through most of the winter. They thrive best in a sandy loam.—DORSKOT.

GARDEN PESTS AND FRIENDS.

Fruit-tree Bark-beetle (*Alexander*).—Your letter is attacked by the grubs of the fruit-tree Bark-beetle (*Scytalus rugulosus*), mentioned in *Gardening Illustrated*. I have nothing to add to what I there wrote, except to say that it is of no use trying to kill the grubs with an insecticide, as the latter would have no effect on the pest through the bark.—G. S. S.

The common ant (*A. Concolor* Reader).

—The insects you sent in a glass bottle were specimens of the common garden ant (*Lasius niger*). This species varies very much in size, your specimens were quite small ones, but ants, like all other insects which have attained their perfect condition, never grow. It is only in their immature states that they increase in size.—G. S. S.

Grubs in field (*Cuscuta*).—The grubs you sent are those of the common Cockchafer (*Melolontha vulgaris*). They are decidedly injurious, as they feed on the roots of various plants, and are very voracious. This insect takes three years to undergo its transformations, and the amount of food it consumes is very considerable. The Cockchafers feed on the leaves of trees, and in this country seldom do any appreciable harm to them, but on the Continent, where they are at times very much more numerous than they are here, they injure the trees very much. There are no means of destroying this insect except by turning up the ground and killing all you can find. No insecticide would have any effect on them. Rooks and Pewees are very useful in destroying them.—G. S. S.

Ross scale (*H. M. T.*).—Your Roses are badly infested with the "White Rose scale" (*Anilacaspis rosae*). I should cut away as much as possible of the affected shoots and burn them, and then spray the plant or paint the shoots over with paraffin emulsion, made as follows: Boil $\frac{1}{2}$ lb. of soft-soap in 1 gallon of soft water. When thoroughly dissolved, and while quite hot, add 1 gallon of paraffin, and churn the ingredients together with a syringe until the mixture becomes white and creamy. In this condition it may be kept for some time, and if properly made the paraffin will separate from the soap. Before using, dilute it with nine times the quantity of water. When applying it, either with a brush or spray, be careful not to leave any part untouched by the insecticide. It is well to use it before the buds open, for otherwise this mixture might be too strong for the opening leaves, which are naturally very tender.—G. S. S.

Black Currant mite.—I enclose a few pieces of a Black Currant bush, which seem to be affected with some sort of disease. As you will notice, the buds have already begun to swell, but in the summer months they form into a knot, resembling a Rose about to open. They never get into leaf, however, and seem to remain dormant all summer. The wood seems to be healthy enough, although I have sent a small piece which seems to be affected.—CONSTANT READER.

[We fear you have not fully read your *GARDENING ILLUSTRATED*. If you had you could not fail to have noticed numerous references to the Black Currant mite (*Phytosus Ribis*). It is that very tiny insect which has infested your Black Currant bushes. Every bud which is swollen or burst is a nest of these mites, and the best remedy is to pick those off and burn them. We judge by the appearance of the piece of shoot sent that your bushes sadly need thinning. Do that first, cutting out all crowded or weak branches, then pick off carefully, as advised, every burst or swollen bud, burning those and the prunings. That will partially check the insect this year; you must, however, follow up the bud-picking each winter, doing it early. Any external applications seem to be of no use in helping to destroy the mite. If you can, remove a few inches of the top soil over the roots and replace with fresh soil and some manure. The sample of wood seems to be none too ripe, showing the need for thinning the bushes freely.]

Value of refuse from making acetylene gas.—Can you tell me if the sludge or lime refuse from acetylene gas is of any value as a manure? I know from experience it is most useful in killing slugs, worms, etc.—ESQUIZZA.

VEGETABLES.

WORK IN FROSTY WEATHER.

WHEN the weather is very frosty then is the time to press forward manure wheeling. Then it can be done cleanly, with less than half the effort required when the ground is wet and pasty, and, moreover, the land is so much better without the puddling attendant on wet weather wheeling. The manure on the ground, the work is practically half done. Gardens infested with insect pests are the better for digging and moving about in frosty weather, and it is the best opportunity for trenching for special crops. Some will say do not bury frozen soil because it will make the ground cold, but I have not found in medium and light soils that any injury is done, but rather a benefit, because of the extra depth to which the ground is pulverised and sweetened by frost. The surface of ground that has been recently dug, and on which, maybe, much rain has fallen, we go over and break up with pickaxe if too hard for forks, which at once exposes an additional depth of surface soil to the action of frost. When frost is past, this soil crumbles down finely, and is in prime condition for seed sowing. Clayey soils are, perhaps, not so well for this extra frosting. Those who have had a long experience declare that spring digging gives the best returns on the clay. When the wind is not too cold, and there is a little sunshine, pruning of garden trees can be done much more cleanly when there is just enough frost to harden the soil. It would not be a good practice, when the wood is hard frozen, to prune. Frosty weather makes the gardener keen on covering up his Celery rows, Potato clamp, Endive, and other things likely to suffer, and provide for everyday use by digging up sufficient root vegetables to carry him over a frosty period. It is a good plan to spread some manure over the ground occupied by roots, as this prevents the frost penetrating deeply, and makes it easier to obtain vegetables should the frost be prolonged. Newly-planted trees, shrubs, or Roses need some provision to keep their roots safe: if strawy manure cannot be given, leaves or clippings from shrubs will afford temporary protection. Anything newly planted repays a covering of some non-conducting substance—leaf-mould, animal manure, dry leaves, Bracken, and Cocoa-nut-fibre are each severally of great value should newly-planted, though hardy, subjects be overtaken by severe weather. The dry stems might be gathered up from herbaceous borders, where this has not already been done, and burned, and returned to the soil while yet dry and fresh. Some fertility by these means would be restored to the soil, and the same may be said of the fruit-tree prunings; they can easily be gathered up when frosty, and those of no value as stakes, cuttings, or grafts, charred in a slow fire.

W.

SPRING-SOWN ONIONS.

If there is one vegetable the gardener prides himself upon growing well it is the Onion, nor does it end here, as the cottager and amateur alike are always eager to point out their Onion bed to those interested in vegetable culture. A clean, well-grown, and well-ripened plot of Onions always proves a source of pleasure to the grower. The ground should have been dug early in the year, but it sometimes happens such work gets unavoidably delayed, hence the remarks given here at so late a date. The ground for Onions cannot well be too rich or too deeply dug, trenched if the soil allows; if not, then it should be double dug or bastard trenched, as it is often called, burying part of the manure with the second spit, and the remainder between the two, and digging the soil or throwing it up roughly as digging proceeds. Manure from the piggery takes a lot of beating for this crop, except it be that from the cow-yard, though many of us have to do without either, and rely upon ordinary stable-manure and decayed leaf-soil thoroughly incorporated together, and the application of some approved artificial manure while the crop is in active growth. Gardeners of the old school thought if the seed were not committed to the ground before the 21st of February, the crop would be anything but

satisfactory, but quite as hoovy crops are harvested to-day if not sown until the second week in March. Soot, as every gardener knows, is an excellent fertiliser for Onions, and I always scatter a moderate layer over the plot before breaking down with the fork, with the addition of a thin coat before the rakes are put over it. The soil must be in good working order ere this work is undertaken, as it requires a deal of preparation before and after sowing the seed, and to attempt to put the crop in on heavy soil while at all wet is to court disaster. The soil ought not to adhere to the feet much while the work is being carried out. Light or sandy soils cannot well be too firm, and a bright, windy day should be chosen to prepare it by forking back the piece early in the morning (especially retentive soils), and allowing it to stand over until the next day if fine weather is likely to last. Give a second forking, then tread the ground over thoroughly before raking off the stones, etc. I prefer treading to rolling, which many advise, as I consider the ground can be made more even with the feet. Next draw the drills, which should not exceed an inch in depth. A three-cornered or triangular hoe is the best tool for this, and the rows are better if running north and south, and must be 12 inches or 14 inches asunder. As regards

Sowing, an evil to guard against is using too much seed, which is frequently done. The labour required when thinning has to be done to what is necessary when thinly disposed in the row is very great. Fill in the drills with the feet and tread the whole plot over again before the final raking is given, making the edges neat with the spade. A fairly calm day is necessary for sowing, or the seed is liable to get blown about. Showery weather is best for thinning the crop, which should be undertaken as soon as the plants are large enough to handle, and it may be necessary to lift the soil a bit with a pointed stick in some cases, but this should be made firm again with the fingers, allowing a space of 4 inches or 5 inches between each plant. In the early morning, while the foliage is wet with dew, dust over with soot once a week or so, which will greatly benefit the crop and assist, if not actually ward off the Onion-fly. Weak manurial waterings occasionally will help to swell the bulbs, when, towards September, the grower should be rewarded with firm, solid bulbs that ought to keep well into early summer. J. M. B.

Samphire.—The story is often related of a party of shipwrecked people climbing up the rocks until they discovered a tuft of Samphire, and then they knew they were safe, for the Samphire never grows when the tide can reach it. Is the above statement true? My opinion differs from this, as I have the recollection of gathering Samphire at the head of Morecambe Bay, on a part of the beach covered by the tide at every time of high water. Wild Celery grows in the same locality. Is this the plant from which our garden Celery has been cultivated?—T. EDWARDS, *Oldham*.

[By the seashore the Samphire is gathered from the rocks, where it grows naturally. Yes, the Celery of our gardens is a cultivated variety of the wild Celery (*Apium graveolens*).—Eu.]

Tomatoes in unheated houses.—In the South of England a very large number of glass-houses are erected without any artificial heat, these being mostly employed for Tomatoes during the summer, and for any catch crop that needs protection in the winter. The time has now arrived for starting operations, even in cold-houses, as the borders need deeply cultivating and liberally manuring, adding also a good proportion of new soil. There is no other crop with which I am acquainted that exhausts the soil so much as Tomatoes. To get the plants strong, the seed should be sown at once in gentle heat, and the seedlings grown on into dwarf, sturdy plants, ready for putting out next month. Sow the seed in good new loam, and keep the seedlings moving gently. Do not give guano or other highly stimulating manures until the fruit is set and swelling, or the chances are that over-luxuriant growth will check the production of fruit. As regards varieties, it is better to

rely on good well-known sorts than to risk the loss of a crop by trying novelties. Chemin Rouge and Ham Green are good useful kinds. —J. G., *Gosport*.

GARDEN WORK.

Conservatory.—Hanging Campanulas, *C. isophylla*, blue and white, and others, are among the useful, easily-grown subjects which can be grown in either the large or small conservatory or the poor man's cottage window. They are pretty in a basket, and equally good in a pot standing on a bracket in the room. All the indoor Campanulas may be increased by cuttings or seeds or by division of the crowns. Cuttings rooted now will flower during the summer if helped on for some time in heat and shifted into larger pots when necessary. There are various greenhouse and conservatory plants which may be raised from seeds, and this is the time to sow. Among these are Balsams and Cockscombs. Balsams will grow anywhere if there are heat, moisture, and light. The last is important to keep the plants dwarf and sturdy. We generally sow in a hot-bed, and move the plants to a drier, but still fairly warm, atmosphere for a time before potting off. Equal parts of loam and leaf-mould, or very old manure and some sand, will grow all this class of plants well. The quality of the blossoms depends a great deal upon the parentage; especially is this the case with the Cockscombs. It is not the ordinary purchased Cockscomb-seeds that will produce the large combs exhibited at the shows. I have generally obtained a small supply of seeds from an exhibiting friend, but this large, highly-fod bloom does not produce many seeds, and therefore they do not often reach the seedsman. The Germans used to have a very decorative strain of Cockscombs, not abnormally large but pretty and interesting; the plant, instead of throwing all its force into one large comb, developed quite a number of smaller ones that were very pretty, and there was considerable variety in colour. This house now will be very gay with various spring flowers. Years ago we had many of the New Holland plants in flower at this season, now we grow Narcissi by the thousand, Lily of the Valley, Spiraea, Azaleas, Rhododendrons, and other forced things in large numbers. Well-grown Lilacs are very useful now, and Arum Lilies, either in groups or dotted about, are striking. Basket-plants may be had in flower all the year round by working on a system of change, which is not difficult or expensive to carry out.

The etove—This is the best season for propagating all plants under glass. Plant life seems more alert, and cuttings root quicker and with more power. It is not necessary to particularise anything. One may take the whole range of the etove and take cuttings from any plant which has young shoots 2 inches or 3 inches long. Bouvardias which have been rested and cut back will be breaking into growth, and when the young shoots are 2 inches long they can be cut just beneath a joint, the bottom pair of leaves removed and inserted in pots or pans of sandy soil and plunged in a good bottom-heat. As regards potting off rooted cuttings, they should be lifted out of the striking bed and hardened for a few days before being disturbed at the root, and after they are potted off, should be returned to the bed for a time to get them started into growth to avoid giving a check. Some plants are now going to rest, others are just waking up to a new life. Among the former are the Poinsettias and Euphorbias, and Gloxinias and Achimenes are just commencing another season's work. The last-named were made much of years ago; at many shows a class was created for them, and very handsome specimens they made when well done. A little two-year-old cow-manure will be an advantage in the compost at the last shift when large specimens are made up.

Early Peaches—regulation of the growth.—The proper thinning of the young shoots (commonly termed disbudding) is among the most important operations in Peach-culture. Under glass we are not compelled to think so much about the value of the shelter of the

foliage to the young fruits as in the open air; still, to avoid checks by the removal of too much foliage at once, the work is best done gradually. This extends for several weeks, beginning, of course, by the removal of all badly-placed shoots which cannot be used for training in to fill up open spaces. So long as there is vacant space on the trellis free growth should be permitted in this direction, but in the case of a full-grown, well-furnished tree, the number of shoots required when the thinning is completed is surprisingly small. One good shoot near to base of each bearing shoot is generally all that is required. The leader, also, must be retained, though, if space upwards is limited, the leader may be pinched when a foot of growth is made.

Early Tomatoes.—Whether grown in pots or planted in troughs or boxes, the soil should be open and sweet, though made firm by pressure or ramming. We want sturdy growth that will set its blossoms, and firmness of the soil assists this in hardening the fibres of the growth. Good sound loam, enriched with soot and some bone-meal, will be suitable. Room can be left for top-dressing if in pots or boxes, and when the bottom trusses are set these top-dressings of rich material will add much to the weight of the crop and do away in some measure with the necessity for so much liquid-manure, which, if used in excess, leads to cracked fruits in the final swelling. The question as to which is the best early Tomato is mainly a matter of opinion. I have had good crops of Early Ruby and Comet. The latter I am growing this season. The old Red was a heavy cropper, but its shape will not do now. Chemin Rouge is a good Tomato. Up-to-Date is not bad, but I want something a little larger. Freedom I have had for a number of years, but it is not quite early enough. Holmes' Supreme is very free, but, like Up-to-Date, rather small. For late work, Lawronson's No. 3 is the heaviest cropper I have had yet, though it is rather coarse in appearance. There is, however, any number of varieties to select from. Keep all growth pinched from main stems, and the leading shoots trained in regularly. Keep the roots reasonably moist and ventilate freely in warm weather.

Figs in pots.—Thin the young shoots freely, and when five leaves have been made pinch the ends of the shoots sufficiently to destroy the tissues and stop further growth. The second crop will start from the axils of the leaves of these young shoots. The cause of fruit-dropping generally arises from irregularity in the treatment, especially as regards watering and temperature. Anything in the nature of a chill, either from using cold water or a rush of cold air through the house, may cause the fruit to drop.

Window garden.—Boxes outside may be gay with bulbs or hardy spring flowers, such as Tufted Pansies, Primroses, Wall-flowers, Forget-me-nots, and autumn sown annuals, such as Nemophila and Saponaria, with trailing Ivies and Periwinkles to hang over box. All these things are cheap, and can, later on, be replaced with others that will last through the summer. Boxes can be planted now with Musk, or some other form of Mimulus for shady windows. Other boxes can be sown with Mignonette by those who desire fragrance. In all cases good soil should be used.

Outdoor garden.—All those who have large flower gardens to fill are now busy working up stock. Cuttings of everything in the soft-wooded way will root now in heat, Geraniums in a dry atmosphere, and Heliotropes, Verbenas, and other things in the hotbed, kept close and shaded for a time. Tuberos and other Begonias are being largely used for filling beds now, and may be raised from seeds sown in heat and grown on in a warm pit for some time. Tubers of Begonias in separate colours may be bought as cheaply as Geraniums now. Petanias and Verbenas are easily raised from seeds, and the plants are more robust and do not involve so much trouble as cuttings. Seeds should be sown in heat now, and the seedlings pricked off as soon as strong enough and started again in heat. These and other things should not be kept in a high temperature longer than is necessary to give them a start, as they will be more robust

grown under cooler conditions. The dwarf Camus make splendid beds on the lawn. These are easily propagated by division, but should have heat enough to start them into growth. Of course they can be raised from seeds, but seedlings do not make such a nice group, as the growth is not regular or sufficiently refined for the work. There is yet time to sow seeds of the various fine-foliated plants used for sub-tropical bedding. The large-leaved plants must have time and warmth to get strong before planting time. Hardy edging plants may be replanted now. The House Leeks have disappeared from many gardens. Golden Thyme makes a neat edging.

Fruit garden.—Flower-buds on fruit-trees, especially Pears, are in some gardens almost ready to burst. The Pear crop is, I fancy, in a critical condition, unless some way can be devised for sheltering the blossoms. Plums and Apples are still backward, but Pear-trees always seem excitable in mild springs. Everything in the way of suitable material for affording shelter should be got ready. It is the cold winds and the storms of sleet which do most of the damage. It would be comparatively easy to arrest the frost, which descends perpendicularly from the clouds, by erecting copings over the trees on walls, and drawing a double thickness of fishing-net over pyramids and bush-trees. At the present time, and in the near future, the Pears, Apricots, and Peaches are the trees we must first think about. To keep up a supply of forced Strawberries, fresh plants with plump crowns must be introduced every ten or fourteen days. The latest batch that forms the link between the crop under glass and those altogether outside may come on in cold pit, or be growing on a south border sheltered by frames. I should like to know how those who have adopted what are termed "travelling houses" find them answer? No doubt good crops could be grown under glass in this way by a competent man, but will it pay for the increased outlay and extra wear and tear? Houses may travel easily when new, and all things work smoothly, but what is the result after five or six years?

Vegetable garden.—The land which has been turned up during the winter works splendidly now, and a good many amateurs are busy in the garden. Of course, the practical gardener always has his hands full, and will have his seed bags out sowing various small crops of early things. The main thing, of course, is to get the land into condition, reasonably manured to suit the various crops. No one would apply fresh manure to land intended for Carrots or other tap-rooted plants, neither should the plants which bear pods receive much nitrogen, as they can gather what they require from the atmosphere, and nitrogen runs the plants into straw, and reduces the pods. Basic slag was first brought into notice as a manure for Grass land, but it is now being used for Potatoes and other crops, and its price being reasonable, it is likely to be more called for as a dressing for land deficient in potash and phosphates. Many of the proprietary chemical manures are too high priced for profitable use in our changeable climate, when the absence of rain at a particular season may render the manure of no avail. One of the most valuable crops in the garden now is the Winter Spinach, but the result is often spoiled by sowing too much seed and leaving the crop unthinned. I often see it in this condition in modern-sized gardens. The good gardener, of course, knows better.

E. HODGAY.

THE COMING WEEK'S WORK.

Extracts from a Garden Diary.

March 2nd.—Pruned back Ivy on walls and edgings. Several overgrown shrubs in the backgrounds of shrubberies have been cut back—some of the oldest have been grubbed to make room for better things. Details of this kind of work are done every season. In some cases openings are made for choice Conifers, Hollies, or coloured-leaved trees, as the Purple Beech, Scarlet Oak, or Silver Poplar (P. Boleana). The roller is used often now on lawns and walks.

March 3rd.—Moved from Mushroom house Rhubarb roots which have been forced. The roots are placed outside for winter and sheltered

with a little long litter. By-and-by the strongest crowns will be planted out again to make stock. Sowed several kinds of Onions, including White Globe and James' Long Keeping. For earlier use we sow in boxes and plant out in April. This follows the autumn-sown plants. Parsnips also have been sown. Early Carrots in the frame are now nearly fit to draw. Successions are sown on the warm border. Radishes are plentiful.

March 3rd.—Peas and Beans which have been started under glass have been planted out, the Peas protected by a few evergreen branches on the windward side of the row. Sowed Asparagus-seeds to raise young plants for transplanting. Removed covering the Globe Artichokes, and forked in all the soil material to improve the soil round the plants. By-and-by, when they begin to grow, suckers will be taken from the old plants and new plantations made. We plant a row or so every year, and clear off some of the old stock.

March 5th.—Potted off autumn struck cuttings of Geraniums. Heliotropes, Fuchsias and Marguerites are shifted into 5-inch pots, early blooming, and cuttings of the young shoots are also taken and rooted in hotel. Pruned back winter-flowering Heaths which have done blooming. The vaporiser is used wherever a green-fly is seen under glass on damp, still nights. Late Peach-house is kept drier when trees are in bloom and the ventilation is free, without draughts.

March 6th.—Gloxinia and Begonia bulb-tubers have been started, the former in pots and the Begonias in boxes. Planted a south-span-roofed house with Melons. Temperature at night 65 degs., air given at 80 degs. A moist atmosphere is maintained. Cleared the winter bearing Cucumbers as another lot is now in bearing, and preparation is being made for planting others. Early Lettuces are being grown in pots.

March 7th.—Thinned early Grapes in forcing-houses, are closed early to shut out some of the sunshine and save fire-heat, damping down at the same time. Put in cuttings of Tree-Carnations and White Finks. The latter are now coming into flower and will be useful for cutting. Hydrangeas and other plants coming into bloom are given liquid manure. Shifted on young plants of various kinds. Put in cuttings of Gardenias and other stove plants.

LAW AND CUSTOM.

Witnessing a will (L. S.).—A witness to a will cannot derive any benefit from its provisions. So long as he is concerned any legacy will be void, but the will as a whole will not be void, and the other provisions, if duly executed, will stand good. A husband cannot derive benefit from a will witnessed by his wife, and an individual who has anything to bequeath should employ a solicitor to draw up a will. It is the foolish and extravagant "economy."

A gardener's house.—I am a groom-gardener and occupy a house sub-let to me by my master at an annual rent of £5, payable quarterly, and the quarterly rent is due on March 25th. I am leaving my service in April, and he tells me I must leave the house at the same time, but there was never any stipulation that I must leave the house when my service terminated. I am rated for the house. Can I claim a quarter's notice, or can he turn me out when my service expires?—READER.

(On the facts stated you are a yearly tenant and are entitled to half a year's notice to quit, and the notice must expire with the end of the year of the tenancy. If your master had desired to retain the power of compelling you to quit when your service expired he should have made an express stipulation to that effect.—K. C. T.)

Agreement for letting house and garden.—A fellow-servant has had bequeathed to her by her master a house and garden. She wishes to let same to a suitable tenant, and wants a form of agreement to be drawn up to him at the rent of £1 per four weeks, to pay rates and taxes, and she wishes it to be understood in the agreement that he is not to sublet any part of the property, and that four weeks' notice is to be given either side to determine tenancy, and that the tenant to keep the house in tenable repair. She is unable to read or to sign her name. In what manner was she to affix her mark? Can I witness her mark? I am a gardener by trade, and am over 21 years of age and a house-owner.—DUMMO.

(The following form will suit your purpose. Agreement made this — day of —, 1903, between A. B., of —, hereinafter called the landlord, of the one part, and C. D., of —, hereinafter called the tenant, of the other part. The landlord hereby lets and the

tenant takes all that dwelling-house and garden, with the appurtenances, situate at —, in the parish of —, and known as —, for the term of four weeks from the — day of — next, and thenceforth upon a four-weekly tenancy, at the rental of five shillings per week, to be paid monthly, the first payment to be made on the — day of —. The tenant agrees to pay the said rent in the manner and at the times aforesaid, free and clear of all outgoings, and to pay all rates and taxes and impositions and assessments made or charged upon the said premises. The tenant further agrees not to sub-let or assign or part with the possession of any part of the premises, and that he will keep the house in good and tenantable repair. The tenancy to be determined on any day by four weeks' notice previously given by either of the parties to the other. (Signed)

"A. B.
"C. D."

The landlord should make a cross against her name, and you may sign as a witness.—K. C. T.]

A question of letting and sub-letting (*Continued*).—A cannot determine the tenancy of the allotment ground by a quarter's notice, but I cannot, from the information before me, say precisely what notice is necessary. If you want advice on the point, you must send an exact copy of the whole of the agreement, and you must say what rent is paid for the land in question. I presume that the rent reserved in the agreement is in respect of the dwelling-house, greenhouse, etc., and that a separate rent is paid for the land. In all probability the tenancy of the land can only be determined by a year's notice, expiring with a year of tenancy, but whenever the owners of the land determine A.'s tenancy by a proper notice, B. and C. may be compelled to quit also.—K. C. T.

BIRDS.

Canary troubled with insects (*Continued*).

—An old wooden cage is often infested with parasites which cause distress and irritation to the inmate. You must scald the cage with boiling water, well scrubbing with strong soda and soap and then rinsing with clean water. When quite dry carefully paint the cage with Fir-tree oil. The nits upon the bird can be destroyed by dusting it with Pyrethrum-powder, or paraffin-oil may be used. To do this hold the bird firmly in one hand, and, with a small camel hair brush, dipped into the oil, touch it here and there whilst blowing up the feathers, taking care to use but a small quantity of paraffin, so that the feathers do not become soiled. If the cage is not very valuable it would be advisable to destroy it and provide your bird with a new one.

Treatment of Nonparail (*F. B.*).—This handsome bird should be fed upon dried ants' eggs, ripe fruit, groats, and Millet. The Nonparail, being mainly insectivorous, cannot thrive on a diet of seed alone, and the injudicious feeding has in this case caused the constipation and fits. It is remarkable that the bird should have remained so long in health upon a diet of Canary and Millet. It would be well to give it a cage to itself, suitably regulate the diet, and, to avert the fits, give two grains of bromide of potassium in a little syrup. The Pin-tail or East Indian Nonparail should have, in addition to the above diet, a liberal allowance of Paddy Rice—that is to say, Rice in the husk.—S. S. G.

Mule breeding (*O. W. L.*).—Very beautiful mule birds are produced by mating a male Goldfinch with a hen Canary. It would be well to remove the Goldfinch from the cage before the breeding season commences. The protracted moulting of the hen Canary may be caused by her being kept in an artificial, over heated temperature, and as such loss of feathers weakens the constitution it would be advisable to provide her with a mild tonic by putting a rusty nail or a little gallon in the drinking water. It is too early in the season for the birds to pair, but about the beginning of April you may encourage this by supplying them every other day or so with a little hard-boiled egg, minced fine, and powdered Osmunda biscuit in equal parts, adding a pinch of each

seed, together about a teaspoonful. Some old mortar should then be pounded and mixed with the grit-sand, and building materials provided, which may consist of dry moss as a staple, together with a little soft meadow-lay and cow-hair. For green food give Groundsel, Lettuce, and Dandelion flowers.—S. S. G.

Treatment of Canary (*V. P.*).—You should, if possible, induce your Canary to partake of a larger proportion of Canary-seed. It is much more likely to remain in good health if fed upon a variety of seeds than if allowed to partake of Rape-seed only. It would be well to gradually lessen the supply of the latter till the staple diet becomes plain Canary-seed—the bird will consume more of this as the allowance of Rape-seed is decreased—and then every other day add a pinch of German Rape. On the days you do not give the Rape place a piece of Apple between the wires of the cage for the bird to nibble. A little Poppy-seed or crushed Hemp may be supplied occasionally. For green food give the flowering tops of Groundsel, Watercress, or Chick-weed.—S. S. G.

Death of Goldfinch (*J. J. Martin Purson*).—Consumption of the bowels caused the death of your Goldfinch, which must have been in a very unhealthy condition when it came into your possession. This complaint would arise from the bird having been improperly fed—its feeding greedily was the result of the disease from which it was suffering. The food for Goldfinches should consist of Canary-seed, the small summer Rape, and Hemp-seed, together with Thistle-seed (or the heads when ripe), Plantain, and the flowering tops of Groundsel. Hemp-seed may be supplied more freely to caged Goldfinches than to any other birds, but care should be taken to decrease the quantity towards the moulting time, or the plumage is liable to become darkened, and the natural beauty of the bird lessened. If properly treated, these birds will live long in confinement, and are fairly hardy. Being lively birds and requiring much exercise a large cage should be provided for them—a square, wooden-topped cage is the most suitable. Sharp grit-sand must not be forgotten, while fresh water for drinking must be supplied daily, and for bathing two or three times a week. This appeared to be a young bird, and was in very good plumage.—S. S. G.

POULTRY.

Scaly legs in fowls (*Old Subscriber*).

You should well scrub your fowl's legs daily with soap and warm water, then rub in zinc ointment. You must use your own judgment as to the amount of scrubbing required, as some fowls are affected more than others. It would be well to treat in this way all birds that may be suffering, and we would advise you to limewash and thoroughly clean the roosting places and perches occupied by the ailing birds.

Water-glass for preserving eggs (*H. P. Brown*).—Water-glass, or silicate of soda, is an excellent thing for keeping eggs fresh for a long time. It is sold by most chemists, and as it is put up in varying strengths, the directions of the vendor should, of course, be followed as to quantity to be used. The usual proportions are, however, 1 lb. of water glass to 1 gallon of water. It should be mixed in an earthenware vessel.—S. S. G.

Indian Runners (*E. P. Weston*).—The drake should have a narrow line of white dividing the base of the bill from the head markings, and the cap from cheek markings. The colour of the breast should be divided evenly from the white. The neck should be long, and the head of a bronzy-green colour; the legs and feet bright yellow and beak dark green. The colour of the shoulders and top of wings should form a heart flattened on the back. The chief features by which pure bred birds can be recognised are the long and slender neck, the quick and active run, the upright carriage, and the narrow body.—S. S. G.

Table birds and egg-producers (*Novitich*).—Houlians and Plymouth Rocks are generally considered the best breeds combining beauty and eating qualities. The Houdan and

binos the shape, size, and quality of flesh of the Dorking, with earlier maturity, is a prolific egg-producer, while the chickens are hardy and rapid in feathering. This breed is generally white (some individuals having black spots about the size of a shilling), boarded, and has top knots of black and white feathers falling backward. The comb is somewhat remarkable, being composed of two flattened spikes of long and rectangular form, opening from right to left, which are thick and fleshy; a third spike grows between these two, having the shape of an irregular Strawberry, while another, quite detached from the others, about the size of a Pea, shows between the nostrils and the beak. The Plymouth Rock is hardy and vigorous, being good at winter egg-production, and, consequently, profitable; the chickens of this breed grow quickly and soon attain maturity, the pullets often laying at five months. Being good foragers and small eaters, they furnish more flesh at a less cost than many table varieties. The hens are good sitters, and careful, patient mothers. Some cross-bred fowls also possess the desirable qualities of being good both for egg-producing and for table purposes, such as a cross between the Mulry or Game and the Brahma.—S. S. G.

CORRESPONDENCE.

Questions.—Queries and answers are inserted in *GARDENING* free of charge if correspondents follow these rules: All communications should be clearly and concisely written on one side of the paper only, and addressed to the Editor of *GARDENING*, 17, Farnham-street, Holborn, London, E.C. Letters on business should be sent to the Publishers. The name and address of the sender are required in addition to any designations and addresses used in the paper. When more than one query is sent, each should be on a separate piece of paper, and not more than three queries should be sent at a time. Correspondents should bear in mind that, as *GARDENING* has to be sent to press some time in advance of date, queries cannot always be replied to in the issue immediately following the receipt of their communication. We do not reply to queries by post.

Naming fruit.—Readers who desire our help in naming fruit should bear in mind that several specimens in different stages of colour and size of the same kind greatly assist in its determination. We have received from several correspondents single specimens of fruits for naming; these in many cases being unripe and otherwise poor. The difference between varieties of fruits are, in many cases, so trifling that it is necessary that three specimens of each kind should be sent. We can undertake to name only four varieties at a time, and these only when the above directions are observed.

PLANTS AND FLOWERS.

Good Pompon Dahlias (*W. J.*).—Twelve good varieties are George Brinkman and Snowflake, white; Emily Hopper, yellow; E. F. Jungler, pale yellow; Baccus, marlet; Arthur West, crimson; Nerissa, rose; Captain Boyton and Douglas, maroon; Unionist and Demon, shades of crimson.

Tulips falling (*Helen Shaw*).—We imagine your culture is at fault. Very probably you placed them in the stove, which was far too hot for them before sufficient roots had been formed. They ought to have been plunged in the open air in ashes or Cocoa-nut-fibre, so as to encourage the formation of plenty of roots before the top growth started.

Streptocarpus (*Flora*).—Plants that have done flowering should be kept moderately dry in a greenhouse temperature till the middle of March or thereabouts, when they must be shaken clear of the old soil and repotted in a mixture of equal parts of leaf-mould and loam, with a liberal dash of silver sand. He sipping of the water until growth begins.

The Karaka Nut (*Corynocarpus levigatus* (*Mex. Hartwegii*)).—This is a native of New Zealand, with white flowers in terminal panicles, fruit somewhat resembling a Plum. It grows well in peat and loam, with silver-sand added, and will do well in a warm greenhouse; in fact, the same treatment as is given to the *Ardisia* will suit it. The other plant you ask about we do not know.

Cineraria leaves unhealthy (*A. Constant Reader*).—Your *Cineraria* leaf has been attacked by the grub of the Marguerite Dandy-fly. The best way, if the plant has been attacked severely, is to cut off the leaves and burn them, or if the attack has only just begun, to pinch the leaves at the place where the grubs are. Spraying with an insecticide can do little good, as it would not reach the grubs. It might, however, prevent the flies laying their eggs if the insecticide could be applied at the right time.

Genista fragrans, striking (*A. B. C.*).—The half-pint shoots of the *Genista* and *Sauria* fringed with inserted in sandy soil and the pot plunged in a tub of cold water. They may be also struck during the summer if the cuttings have a bell glass put over them and the glass shaded; but they take much longer to root in this way than they do in heat. Cut down the old plants directly they have finished flowering, and when the young shoots commence to grow repeat, using a compost of equal parts of loam and leaf-mould, with a sprinkling of sand. Stand them out-of-doors during the summer in a sunny position, so as to ripen the wood well, and thus cause the formation of flower-buds.

Potting Tuberous Begonias (*Leon*).—One year old tubers are very suitable for growing on. Pot them in size into 3-inch pots, shifting them on as may be necessary. If you have any more, they will, of course,

need an increased size of pot at first and also later on. A mixture of equal parts of loam and leaf-mould, according to its consistency, will suit Tuberosus Begonias, while as the pots get full of roots a little liquid-manure will be beneficial. Do not allow your plants to carry any seed pods as these are very weakening.

Ericas after flowering (*Mrs. E. M. Bird*).—Cut the plants into shape, shortening back the long, vigorous shoots to one-third their length, then place them in the greenhouse, where they will start into growth. As soon as the young shoots have grown about half-an-inch, repot into sandy peat, pressed very firmly. Keep them in the greenhouse or in a frame kept close till they have recovered from the check, then stand them in the open, watering carefully till the cold nights come, when remove to the greenhouse.

Clematises from cuttings (*L. H. White*).—The usual stock on which Clematises are grafted is the roots of the Traveller's Joy (*Clematis Vitalba*). In increasing from cuttings select the young shoots when about 4 inches long, with a small heel of the old wood, and insert them round the edges of clean, well-drained pots in sandy soil. Then place in a propagating-case in a warm greenhouse, treating in the same way as cuttings of Fuchsias, etc. Layering may also be done now, burying some of the flexible shoots that are handy for the purpose. Tongue the stem below each joint and bury not too deeply in the soil.

Plants for greenhouse (*R. L. Allen*).—Had the question been more explicit it would be possible to answer it in a more satisfactory manner, but a selection of a dozen greenhouse plants without any clue to your requirements, or to the facilities you have for their culture, is almost impossible to give. If for maintaining a display during the coming season, perhaps you would prefer such subjects as Tuberosus Begonias, Pelargoniums of different sorts, particularly the double-flowered Ivy-leaved class, Fuchsias, Heliotrope, Abutilons, flowering Cannas, Lilium longiflorum, Lilium speciosum, and Lilium auratum, with Passiflora Imperatrice Eugenie, the white-flowered Passiflora Constance Kilini, and Plumbago capensis, with pretty light blue flowers. If we have not fallen in with your views please give a more detailed account of your requirements.

Furnishing a window-box (*J. A. W.*).—If you could put in the front of your window-box in May, or so soon as you could after the Crocuses were out of bloom, a few plants at the hardy Caring Jenny, then obtained a dozen or so of Panies of two or three colours, but especially white, and amidst those planted some three or four small white and red Fuchsias, your box, although on a north window-sill, should look gay for the summer. It is not wise to plant too many kinds of plants, but a few such as those named, done well, give the best effects. You should, ere you replant, turn out all the old soil, thoroughly wash the box, then refill with quite fresh soil, largely of fresh loam, with some well decayed manure, leaf-soil, and sand added. See that the holes in the bottom of the box are open, and place a little rubble drainage in the bottom before filling with soil. When so doing, place the rougher portions over the drainage first. The middle at Manchester is hardly a good place for flowers.

Growing Daphne indica (*V. A. G.*).—After flowering keep the Daphne in a greenhouse—that is to say, a structure with a night temperature of 45 degs. to 50 degs., with a rise of 10 degs. or so during the daytime. It should be given sufficient water to keep the soil moderately moist, and is greatly benefited by an occasional syringing during bright weather. It will often stand for two or three years without repotting, but when necessary this operation should be carried out directly the flowers fade. A good soil for this Daphne is a mixture of equal parts of loam and peat, with a liberal sprinkling of sand. When the spring frosts are past it may be gradually hardened off and stood out-of-doors. This is not an easy plant to strike from cuttings. The best cuttings are the shoots of the current season's wood, taken about July when they have become fairly woody. Dibble these into well-drained pots filled with sandy peat, and stand, after having well-watered them, in a little bottom-heat. This Daphne, too, can be increased by layers. In nurseries it is grafted on the Spurge Laurel or the Mezereum, but such plants often die off suddenly.

TREES AND SHRUBS.

Pruning Pyrus japonica (*A. K. L.*).—This will always flower better when allowed to grow naturally than when closely pruned. Such being the case, it should only be cut back so far as is really necessary to keep it within bounds. Any old or exhausted shoots should be cut clean out, as by so doing the young, clean growth on which depends a good deal of the future display is encouraged. A good time for doing this is as soon as the flowering period is over, as then there is a long growing period before it. You may, if you do not wish the plant to grow too far away from the wall, shorten in the season's shoots, and thus induce the formation of spurs or flower-

buds. This can be done, of course, immediately after flowering. Lay in the best of the young wood, and spur back any that is weak.

FRUIT.

Soil for Strawberries (*W. H. N.*).—Any fairly good loamy soil does Strawberries well. If yours is too light and porous, as is so much of the soil about Richmond, the addition to it of some clay from deep drains or sewers, spread on the surface 2 inches or 3 inches thick early in the winter, allowed to lie two months, then dug in and well mixed with the soil, some half-decayed manure being added, should do great good. Failing that, you should obtain, if you can, one or two cartloads of loam from a field where new houses are being erected. A few bushels of fresh soil would be of little use added to a breadth of ground from 2 rods to 3 rods in area. To have any material effect you need much more. If you got from where building is proceeding, a few spadefuls should not cost very much. You can obtain plants from any nursery in your neighbourhood. Runners of last year dibbled out thinly then should be extra strong well-rooted plants now.

Fruit-trees on walls (*C. M. N.*).—As your note refers to Peach as well as Plum and Pear-trees, we assume that you have your trees against walls, and flat-trained. As they were planted but fourteen months since, we hope then that you gave them a fairly hard pruning. It so, it will be the growth of last summer you now refer to. These shoots may well be cut back to from one half to two-thirds their length, as if left full length back buds would not break, and the branches would thus be rather bare. Peach fruit from young wood as well as from spurs; and in pruning them the best or stoutest of the shoots should be nailed to the wall and be partially shortened, weak ones being cut out. Any that break out from the fronts of branches should be cut clean out also. Treat Plum in the same way. These chiefly fruit from spurs, which are formed naturally, or by cutting back in July young shoots to four leaves, then in the winter to two buds, and these eventually form rooting spurs. Pears need similar treatment. Apply manure to the trees in May after the soil has become warm, and then only as a surface mulch.

VEGETABLES.

Growing Land Cress (*H. Johnson*).—The culture of this is very easy. The seed may be sown during the whole of the spring, summer, and autumn in any kind of garden soil. Successional sowings are not necessary, as there is no fear of the plants running to seed too soon. Its produce is not so valuable at that of the Water Cress or the common Garden Cress, as the leaves are always hardish, and their pungent flavour is always accompanied by a certain amount of bitterness.

Manuring garden (*K. L. D.*).—If you have already given your garden a fair dressing of manure, the proposed dressing of artificial manures seems rather superfluous. Most probably you would have obtained far better crops had your ground been trenched 2 feet deep, leaving the bottom soil below, but well broken up, and adding the animal manure to that before putting the top 6 in. of soil on it; that would have encouraged the roots to go deep in search of the manure, and they would have sustained crops in dry weather so very much better. Then you could have forked into the upper soil a dressing of about 5 lb. per rod, of artificial manures. You have in your order of these overdone the phosphate, as superphosphate and bone-flour are practically the same. The phosphate and potash (Kainit), well mixed and crushed, should be cast evenly over the ground at the rate of 4 lb. per rod of 30 square yards at once, and be well forked in; then add a dressing of 1 lb. of sulphate of ammonia soon after crop-growth has begun, well boxing it in.

Growing Cucumbers (*J. O. D.*).—You could raise Cucumber plants from seed in a cool greenhouse, but not very well yet. You must wait till the middle of April, when the sun gives warmth. Set eight seeds in a 5-inch pot, equally distant, in good, fine soil, burying them a little. It would help the seeds to grow if you stood the pot in a larger one, then placed a piece of glass over that, as it would help to box in the sun warmth. You would need four plants for your frame. These should be first got into 4-inch pots singly, or be in pairs in 5-inch pots, and have become strong before they are planted out. If you can fill your pits with some stable-manure and tree-leaves, well mixed and trodden down hard up to within 12 inches of the glass, then on that put 2 inches of turfy loam, and in the centre of each light a mound 5 inches deep, you should put out the plants into those mounds, two in each. Between the dung below and the sun-heat above you should find ample warmth then for Cucumbers.

NAMES OF PLANTS AND FRUITS.

Names of plants.—*Samuel Tuke*.—Kindly send a specimen, and we will name it for you.—*F. L. P.*—1, *Pyrus japonica*; 2, *Comunon Hepatica* (*Anemone Hepatica*).—*Tinsperley*.—Quite impossible to name from only one flower.—*Flash*.—*Kuscus racemosus*.

SHORT REPLIES.

E. P. S.—We doubt very much if you will be able to move your Nectarine tree with any hope of success so late in the season. If you do you must be prepared to sacrifice all hopes of a crop.—*M. C. L.*—Leave the mulching as it is, or if you object to the manure you can sprinkle some soil over it.—*M. B.*—Your best plan will be to write to some large grower of fruit-trees, such as G. Buoyard and Co., Maidstone.—*J. M.*—Apply to Amos Perry, Winchmore-hill, N.—*Mrs. L. Edrington Malton*.—Very possibly it is owing to the unfavourable season we had which prevented the wood becoming properly ripened.—*Hoadenshire*.—You can buy weed-killer readily prepared cheaper than you can make it. Consult our advertisement columns.—*C. T.*—We suppose you mean *Doronicum*, which is known as *Leopard's-bane*.—*J. B. D.*—See reply to J. R. Clements in our issue of Dec. 27, 1902, p. 505, re "Hardy Flowering Plants for shady positions." Of course, any of the hardy native Ferns will do well.—*Buquiter*.—We can find nothing on the Black Current shoots that you send.—*D. M. G. Peck*.—We have no knowledge of what the rule in your neighbourhood is.—*E. Wynora*.—You ought to have protected your blooms with handlights in some way, as then they would develop well and be fine in colour. They have evidently been preyed on by slugs and injured by storms.—*Mrs. E. M. Bird*.—See article on Asparagus, in our issue of Jan. 31, p. 617.—*American*.—Consult our advertising columns.—*A Lover of Flowers*.—Quite impossible to advise unless you can give us some more information as to what conveniences you have for raising and growing plants.—*J. H. Wright*.—You need not be alarmed, only take care that you do not buy any trees that are suffering from American blight.—*A Constant Reader*.—Do you mean an outdoor or an indoor Hibiscus?—*Acton*.—The only cure is to fumigate the house in which the plants are.—*Mac*.—See reply to "S. W." in our issue of Jan. 31, p. 618, and also reply to "S. W." in the issue of Feb. 21, p. 620.—*Reader*.—You will find an article dealing with the City of the Field (*Sternbergia*) in our issue of Nov. 22, 1902, p. 467, which can be had of the publisher, post free, 4s.—*Harold Shaver*.—You will find a fully illustrated article dealing with wall gardens in our issue of Dec. 20, 1901, p. 553, which can be had of the publisher, post free, 1s.—*M. J. K.*—You had best write to the Secretary, Zoological Society, Regent's Park, London, N.W.—*K. N.*—Yes, you might plant the Myrtle, but if the soil is heavy you will have to add some material to lighten it, also taking care that the position is well drained. If the weather is very severe, you will have to protect during the winter.—*Anxious*.—If you not leave the creepers alone altogether? It will die on Nos. 1 and 2, seeing that you will, by cutting the part covering No. 3, have severed the connection with the roots. You cannot compel the owner of No. 4 to cut it off No. 3, but you can do so yourself. It is a pity you cannot allow a little "give and take." The litter of leaves is very slight and only in the autumn, and yet you intend spoiling the effect of a row of creeper-clad houses by laying bare the one in the centre.—*Mrs. Harvey*.—See reply to H. C. Wilcox on Hyacinth culture in our issue of Feb. 7, p. 624. You kept your Hyacinths too warm when first potted, and it is not at all surprising that they have failed.—*Wilde*.—You ought to get a copy of "The English Flower Garden," in which the subject is fully dealt with. We have no objection with the subject in our issue of Feb. 1, 1902, p. 611 (with illustration), which can be had of the publisher, price 1s. See article re "Christmas Roses," in coming issue.—*B. K.*—"Table Decoration," by Wm. Low, Chapman and Hall, publishers, London.—*Obituary*.—Not a gardening question.—*Tulip*.—The Hyacinths you have grown in water are of no value for next year's flowering. You can, of course, lay them in boxes of soil, watering till the foliage dies down, and then treat in the same way as recommended for Hyacinths in pots.—*A. C. G.*—The manure you refer to is of no value, as the wood-shavings will only breed fungus and cause you a deal of trouble.—*H. G. Thomson*.—Far better defer the pruning till the early weeks of March.—*Tulip*.—See reply to your query re Ferns, in our issue of Feb. 14, p. 623, under "Short Replies."

Catalogues received.—Sutton and Sons, Reading.—*Parmer's Year Book and Grower's Manual*.—W. H. Hudson, 34, Chiswick High-road, W.—*List of Bulbs, Lilies, Seeds, and Plants*.—Gartons, Warrington.—*New and Improved Breeds of Farm Seeds for 1903*.—Amos Perry, Winchmore-hill, N.—*Supplement to Paris I and 2 re Hardy Border and Rock Plants*.—Little and Ballantyne, Carlisle.—*Agricultural Seeds*.

United Horticultural Benefit and Provident Society.—The annual general meeting of this society will be held at the Caledonian Hotel, on Monday, March 9th next, at 8 p.m. Mr. John Green, of Dereham, Norfolk, has kindly consented to preside.

END OF VOLUME XXIV.
